

## Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

## Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

- + *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
- + *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
- + *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
- + *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

## Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter <http://books.google.com> durchsuchen.

# Jarris and Gale Lectures

ON THE  
RELATION OF EXPERIMENTAL PHYSIOLOGY  
TO PRACTICAL MEDICINE.

*Delivered at the Royal College of Surgeons, June, 1882,*

By G. F. YEO, F.R.C.S.,

PROFESSOR OF PHYSIOLOGY IN KING'S COLLEGE.

## LECTURE II.—PART II. THE GROWTH OF PHYSIOLOGY.

BUT has experimental research been silent concerning the circulation since the time of Harvey and Malpighi? Certainly not. The great microscopist, Leuwenhoek, working almost at the same time as Malpighi, confirmed his observations and demonstrated the capillary circulation in the frog's web, and other transparent tissues. He discovered the red blood-corpuscles, or globules as he called them, which were afterwards shown by Hewson to be discs. Another fundamental step in the comprehension of the vascular mechanism was made by an Englishman, a doctor of divinity—the vicar of Teddington. The high pressure comes next in importance to the contracting power of the ventricle for the understanding of the blood-flow, which, without a knowledge of this continuing force, the constant overflow from the arteries into the veins through the capillaries cannot be properly understood. Without a due appreciation of the force with which the blood tends to escape from the arteries, how can the surgeon well estimate the means he must adopt to check its flow from a severed vessel? In 1732 Dr. Stephen Hales published his *Statical Essays*, which contained an account of the experiments on living animals which he performed to estimate the force of the heart. By means of the trachea of a goose he connected a long tube with the crural artery of a mare, and he found that the blood rose to the height of some eight feet. On the other hand, he showed that the pressure in the veins was very low, being on an average ten times less than that in the arteries. The manometric method introduced by Hales was greatly improved by Poiseuille who used the mercury gauge. The whole question of hæmodynamics was fundamentally investigated by Volkmann. The graphic method which enables us to preserve such accurate records of the changes occurring in the circulation under different circumstances—the sphygmographic tracings of every well-educated physician—was introduced by Ludwig.

It is remarkable that just about the time when the view of the ancients regarding the active propelling power of the arteries was thought to be satisfactorily refuted, the existence of contractile elements in their walls was first definitely made out. Haller convinced himself of the existence of muscle tissue in the coats of the arteries and of the nerve influences controlling it, although he could not observe it to respond to ordinary stimulation. Cullen, adopting Haller's view, assigned to the arteries the power of controlling the distribution of the blood to the several parts of the body, while the force and frequency of the heart-beat remained the same. The experiments of John Hunter on the contractility of the arteries of the horse next followed. The demonstration of the actual occurrence of the contraction in response to different stimuli in the living frog's web, by Dr. John Thomson, placed the matter beyond doubt. It remained for Claude Bernard to demonstrate by vivisection the paralyzing effect of section of the sympathetic nerves in the neck upon the vessels of the head. Immediately afterwards Dr. Brown-Séquard observed that the electrical stimulation of the distal end of the divided sympathetic caused the small vessels to contract, and thus brought back the pallor of the part. From numerous sets of experiments we now know the wonderful nervous and muscle systems that belong to the vaso-motor mechanisms, which are constantly employed to regulate the blood-supply to the various organs and parts. By means of experiments on living animals almost daily additions are being made to our knowledge of this important subject. The practical value of these details is, I think, sufficiently

No. 3071.

proved by the fact that many of them were discovered during the practical investigation of the processes of inflammation, which lies at the root of all pathological science. I shall, therefore, only remind you of the important facts: (1) That our methods of arresting bleeding have been improved; (2) our means of alleviating cardiac disease have been extended; (3) and our knowledge of the pulse, as well as our method of investigating it, have been completely changed by such additions to our knowledge as those I have just mentioned.

And have we gained any practically useful knowledge of the capillary vessels since the days of Malpighi and Leuwenhoek? We have learned by the vivisections of Waller and Cohnheim that their walls are permeable not only to the fluid but to the solid parts of the blood, and that under certain circumstances the white corpuscles may be seen to creep through the plastic wall of a capillary or small vein without leaving the least trace of their exit. Not only does fluid pabulum pass through the textures, but also protoplasmic units; active formative agents emigrate from the vessels and wander through the interstices of the tissues. From Cohnheim's experiments with emboli in the frog's tongue, we know that when a little area of capillaries is for some time deprived of its blood-supply, the wall of the vessels undergoes some change (arising from malnutrition), loses its power of retaining the blood, which consequently escapes into the textures around. Of the blood itself we also have learned much of recent years that is practically useful. Besides the part played by the fibrin-factors in bringing about coagulation, we have been shown that the lining wall of the vessels bears to the blood a remarkable relationship, by means of which coagulation is constantly held in check. Thus a kind of interaction, a mutually protective or reconstructing interchange, seems to occur between the blood and the tunica intima, particularly in the minute vessels.

From the foregoing examples, it is evident that the general explanation of how the blood—the universal carrier of both food and waste-products—travels through our frame, was from first to last demonstrated by experiments on living animals. I need not pause to inquire what the probable effect of not possessing this knowledge would be even to the most unscientific routine practitioner!

I must now rapidly glance at the function of respiration.

Before Malpighi demonstrated the vesicular texture of the lungs and the passage of the blood through their capillaries, but little was understood of the manner in which the blood passed from the right to the left side of the heart. Though the fact that the blood must pass thus through the spongy lung tissue was, as we have seen, long known, its relation to the air must have remained a complete mystery until the dense meshwork of capillaries, well called the "rete mirabile Malpighi," was discovered. But even when the air cells were familiar to all physiologists, and the mode of exposure of the blood in a wonderful network of vessels had been demonstrated on living animals by the aid of the microscope, the process of respiration was but very imperfectly understood, and the true relation of the respiratory movements to the motion of the heart and the flow of blood in the arteries was quite unknown.

It was the prevalent opinion among the ancients that the air passed through the lung into the pleural cavity. This opinion continued down to the time of Haller (1747) and received the sanction of all the great authorities in the beginning of the seventeenth century, including Harvey, Hales, Boerhaave, &c. This error arose partly from the condition of the parts found in post-mortem examination of the human body, when the lungs are usually in a collapsed state, and partly from experimentation upon birds. It was only by a series of experiments that Haller disproved this theory. Is there anyone who can be so ignorant of the value of the physical methods of examination as not to recognise the practical importance of a correct knowledge of the relation of the pleura to the lung and to the chest-wall? Apart altogether from its physiological importance as an item in the comprehension of the mechanism of respiration, would not ignorance upon this point cut us off from all possibility of physical diagnosis in pulmonary and pleural complaints? Have these experiments of Haller's, then, proved of more than purely scientific value, and have they done more than "satisfy scientific curiosity and quench the selfish thirst for knowledge?"

It was the distinguished English physicist Boyle who first pointed out that the lungs were filled by the atmospheric pressure. The thorax, he said, acted like a bellows; when it

610.5

L2

dilated the air was forced into the trachea and filled the lungs. This he compared to the distension of a bladder into which the atmosphere rushed when the air around it was removed by an air pump, an instrument which was, at that time, a great novelty. But this simple view deprived the lungs of all their vital action in causing the motion of the blood, and, though amply demonstrated, was not received as correct for a long time afterwards.

From an inspection of the anatomy of the thoracic viscera and the beautiful and complicated apparatus by means of which the air and the blood were brought into immediate relationship one to the other, it was but natural to conclude that the use of the lungs was to enable the air to produce some change in the blood. Indeed, before the anatomy, either of bloodvessels or lungs, was understood, we had learned from Servetus that the vital spirit of the air was supposed to have a definite effect upon the blood. From the moisture and warmth of the expired air it was concluded by the more cautious physiologists of olden times that the air removed from the blood some of its moisture and heat, and thus refreshed it as well as added to it new vital spirits. The absolute necessity of constant and uninterrupted respiration was recognised by all, but it was attributed to the mechanical effects produced by the respiratory movements upon the motions of the blood. Boyle showed, however, that the air must be fresh in order adequately to supply the requirements for life and to carry off the moisture and what he called the "recrementitious streams." At this time it was pretty generally believed that the blood gave something to and received something from the air. But what that something was chemistry was not yet ready to state. Mayow, by acute reasoning and a most carefully arranged series of experimental researches, in a great measure performed on living animals, arrived at conclusions that were far in advance of his time. He announced that the air of the atmosphere was a compound body, and that it contained as one of its constituents a substance which he called (on account of its relation to nitric acid) nitro-aerial spirit. To this nitro-aerial spirit he attributed the properties of oxygen. It gave the air the power of supporting combustion, and to it were due the vital properties which the air imparted to the blood during its passage through the lungs. It was this nitro-aerial spirit that made the air useful for respiration, and its absence rendered it unfit to support life. But the knowledge at the time when Mayow lived was not ripe for such views. They fell into disuse, and were almost forgotten by his successors. Even Hales, who paid much attention to the subject, seems to have known but to have disregarded the theory of Mayow.

I need not attempt to follow the various stages in the discovery of oxygen, and the application of this all-important piece of knowledge to the function of the lungs, but I would call attention to the experimental steps in advance made by Black and Priestley at a time which may be regarded as the dawn of our modern chemical knowledge. The fact that what was then called "fixed air" (since commonly spoken of as carbonic acid gas, or now carbon dioxide) was present in the expired air, was shown by Black by experiments on living animals about the year 1759, and about twelve years later Priestley showed the analogy of respiration to combustion, and concluded that the air, in passing into and out of the lungs, lost some of what we now know as oxygen. But the great credit of giving an exact explanation of the chemical changes occurring in respiration is due to the eminent French chemist Lavoisier, and the completeness as well as the accuracy of his views may be traced to the constancy and skill with which he experimented on living animals. The more important principles of his writings have since been fully worked out, and, in the main, confirmed by others, so that we now have an accurate knowledge not only of the chief chemical changes that take place between the air and the blood, but also the exact quantities of carbon dioxide given off and oxygen consumed in the process. Need I attempt to point out even to a layman the value of this knowledge? Has it not strengthened our hands in attempting to prolong life and alleviate human suffering? The merest tyro in hygienic study knows how absolutely necessary a knowledge of such facts must be before one attempts to consider the essential point of ventilation. What would have been the fate of the hundreds of persons who have been revived by artificial respiration had we not known the mechanism of breathing? What would we now do without physical examination of the chest? and how would we proceed did we think the pleural cavity full of air?

Having learned the changes occurring in the air during its visit to the lungs, there still remained the important questions to answer:—What changes take place in the blood? what becomes of the oxygen? whence comes the carbon dioxide? The difference between the colour of the blood flowing through the veins and that in the arteries had long been remarked, and since the time of Galen had been attributed to the vivifying action of the heart itself, the centre from which emanated the heat and vital spirits. The first light thrown upon this point came from a most admirable series of experiments made by Lower. By opening the thorax of a living animal he found that the change in colour took place in the pulmonary capillaries, and not in the heart cavities. Though as clearly demonstrated as any scientific fact so surrounded with difficulty could be, this instructive observation of Lower remained unnoticed by his immediate followers as well as by his contemporaries. Not until Priestley showed the effects of the exposure to the air of a blood-clot was the scarlet colour of arterial blood regarded as a change probably brought about by the air acting on the blood in the lungs. Now that we are well acquainted with the red corpuscles and their colouring matter, and its wonderful relationship to oxygen, it seems difficult to understand why Lower's views did not meet with immediate approval. And now that we know that white blood-corpuscles are the active agents which preside over the repair of our injured or worn-out tissues, that the serum conveys pabulum to these, and that the oxyhæmoglobin supplies them with oxygen, we should shrink with alarm if it were proposed to apply twenty leeches over the apex of the lung of a phthisical patient, or to take thirty ounces of blood from the arm in the early stage of typhoid fever.

The attention of the ancients was exclusively devoted to the stomach as the organ in which the necessary changes took place in digestion. First of all these was supposed to be simply "concoction," a process dependent solely upon the moisture and heat of the stomach. From some of the coarser changes which would be observed in the food stuffs as they passed along the small intestine, it was afterwards supposed by others that the chief change was one analogous to putrefaction. From the elaborate muscular stomachs in birds and some other animals another set of physiologists put forward the view that the only essential in digestion was trituration, a view which, though supported by but slender evidence, required the experimental contradiction of Spallanzani for its complete refutation. In opposition to the latter view the theory of fermentation was stated, which term, however, at the time when the earlier chemists flourished, had a very different signification to that which it now bears. It was not until definite experimental research was instituted that the secretion of the gastric juice became known, and its effects on certain kinds of food were tested by Stephens and Spallanzani. Time will not permit me to mention in detail the numerous series of experiments which showed the chemical composition of the gastric juice and its effects on proteid food as well as its inertness on other food stuffs, nor the investigations which led to the comparatively recent discovery of the widespread activity of the pancreas (to which the ancients assigned the modest function of a protective pad), nor those on the value of the succus entericus. It is sufficient to say that by means of experiment on living animals we have arrived at a fair knowledge as to where and how the various food stuffs are changed in digestion. And I would ask any practitioner, however opposed he may be to experimental research, can he ignore the mode of action of the gastric, pancreatic, and intestinal juices on the different foods when prescribing any special dietary; and is he aware that most of the important points that form the basis of his practice have been elicited by vivisection, possibly during his own lifetime?

In order to appreciate the influence of experimental research on the progress of the knowledge of the physiology of the nervous system, it is well to bear in mind the views of the ancients upon this subject. The brain was deemed by them to be a large gland, secreting certain subtle animal spirits, which were distributed by the nerves to the different tissues of the body. "The nerves," says Galen, "like streams from a fountain, convey to the muscles their powers from the brain." The flow of this nervous fluid being difficult to detect, it was subsequently supposed that merely vibrations occurred in it, and no real material current. When the knowledge of electricity came to enlighten physicists concerning so many difficult phenomena, nerve

force was supposed to be traceable to its influence—or, in short, to be electricity. It is only owing to the numerous experiments on living animals that we now know that a nerve impulse is the rapid transmission of a chemical change or protoplasmic explosion, as it were, passing along the axis cylinder of the fibre. It was in the earlier part of this century that by the experiments of Sir Charles Bell, Magendie, and Johannes Müller the distinction of motor and sensory nerves was definitely established. This was the first great step since Galen, and was the key to the understanding of the functions of the nerve centres. Without it Whytt and Prochaska were but groping in the dark. It was chiefly by following the question of the functions of the roots of the spinal nerves by repeated experiments on living frogs that Johannes Müller was led to his accurate conclusions as to the functions of the spinal cord. But it is, no doubt, to our fellow countryman, Marshall Hall, that most credit is due for both originality of discovery and energy in advocating the laws of reflex action which really form the basis of our present knowledge of the uses of the nervous centres. Now we have a precise acquaintance with the localities in which lie the nerve cells that preside over many of our most important organic motions, such as respiration, deglutition, &c.; and a kind of localisation of higher functions seems to be promised by certain modern methods of experiment, which have so far only given results which tempt the sanguine physiologist to look forward to great advances in psychical therapeutics.

Any account of the growth of physiology would be most faulty which did not give prominence to the name of Albert von Haller. By his exertions as an experimentalist, a teacher, and an author, Haller gave a most powerful impulse to the study and progress of physiology. His original investigations have given us a series of results unequalled in number, accuracy, and importance by those of any other physiologist. But Haller's claims to the gratitude of posterity rest less, perhaps, upon the discoveries which he himself made than by his bringing together in his "Elements of Physiology" all that was known of this science, which had been previously scattered throughout the cumbersome writings of the numerous earlier observers and experimenters. Further, he created a spirit of experimental research which had never before existed, and which, I hope, will never again disappear from our methods of medical study. He gave the first short and comprehensive view of physiology that ever appeared. In short, Haller may be said to have created our science as it now is, and he has been well called the father of physiology. I have here his "Præparatæ Lineæ," which is the oldest and one of the best student's handbooks of physiology. Our science, then, which was conceived in the days of Galen, was only born in the eighteenth century, having undergone a remarkable quickening in the time of Harvey.

It is in connexion with the irritability of muscle, independent of the nervous system, that the name of Haller is most familiarly known, for this was the point raised by him which gave rise to the wide-spread pathological theories which I mentioned in my last lecture. Galen and all his successors believed that the activity of muscle came from the brain or the cord. "All the muscles," says Galen, "have a communication with the brain and spinal marrow; for they must receive from the brain or the spinal marrow a nerve which, though small in appearance, is by no means inconsiderable in power . . . . There is certainly some great power in the nerves, flowing into them from their primary organ, for they have it not in themselves, neither do they originate it in them. This is proved most distinctly by the fact that if you divide any of the nerves, or the spinal marrow itself, the part above the incision and in continuity with the brain will still retain its powers; but the part below will be incapable of producing either sense or motion." The first dissentient from this view seems to have been Glisson; and he also first used the term irritability as applied to a muscle independent of its nerve. Indeed, he also seems to have had an idea of reflex action. According to him muscular fibres may contract in response to three different kinds of stimuli: (1) To those applied to them directly; (2) to a sensory stimulus coming from without through the medium of the nerves; and (3) to a voluntary impulse arriving from the brain. Haller explains the matter much more fully and clearly than Glisson, and applies his views to all the motions of organic life. He says, "Every muscular fibre when irritated contracts itself, and this character distinguishes it from the vegetable fibres, and perpetual irritation alone is the cause of the continuation of motion in the vital organs, after the

animal organs had ceased to move. . . . The irritability of the muscular fibre is independent of the nerves and of all known property." Elsewhere he says: "Irritability is different from elasticity, and from the dead contraction common to all fibres; it seems to constitute a power which is quite peculiar to the muscular fibre, and characteristic of it, so that every muscular fibre may be said to be irritable; and, on the other hand, everything which is irritable may be said to be muscular fibre. It is a power distinct from every other power and to be referred to the sources of motion—of the ultimate cause of which we are ignorant." How apposite is Haller's muscle-force at this moment, when there is a difficulty in explaining some vaso-constrictions which occur without nerve influence and vaso-dilatations which follow nerve influence.

Although Germany be the cradle in which our comparatively young science is now fostered, I think, from the sketch I have given, it may be gathered that England has made a fair contribution to modern physiology.

Are English physiologists now to stop working, or must they proceed with the heavy incubus which has been placed around their necks by the opponents of experimental research?

## COMPOUND SUPPURATING HYDATID CYST OF THE LIVER,

TREATED SUCCESSFULLY ON THE ANTIREPTIC PLAN.

By JOHN COCKLE, M.D., F.R.C.P.,

SENIOR PHYSICIAN TO THE ROYAL FREE HOSPITAL;

AND

WILLIAM ROSE, F.R.C.S.,

SURGEON TO THE ROYAL FREE HOSPITAL.

SIMPLE hydatid cyst of the liver is far from uncommon; its diagnosis is generally easy, and its treatment successful. But simple cysts may change at times into those of compound form by fusion or otherwise, and yield a high death-rate from the accidents of size, situation, laceration, or change in the nature of their contents, and occasionally from the very means adopted for their destruction. The case to be described would fall under this second division, and may be thought worthy of notice, not only from its special complexity or the freedom of the operative procedure, but from the unusually large amount of hydatids discharged during the progress of the treatment (to state the number; at two thousand would probably be an under-estimate), and also from the apparent completeness of the cure, without the occurrence of any untoward symptom of more than transient duration.

Thos. M—, aged thirty-seven, unmarried, was admitted into the Royal Free Hospital, under the care of Dr. Cockle, on Nov. 22nd, 1881, with the following history. He comes of a healthy family. Was formerly a commercial traveller, but for the last four years has been in the police force. He has been subject at times to a cough in the winter, unattended by any shortness of breath. Has had no previous illness beyond an attack in 1875, supposed to be lumbago, which lasted six weeks. Since then he has suffered at times from wandering pains in the back, and more or less from weak digestion and some failure of the appetite. Within the last year or two he has got thinner and become paler, and eventually observed that his feet and ankles were swollen at night. In the beginning of November he states that he caught cold, followed by shivering, subsequently recurring at irregular intervals, with severe cough and difficulty of breathing. However, he still kept on night duty, but was at length compelled to go on the sick list for bronchitis. On Nov. 20th he felt great pain in the pit of the stomach, which was relieved by the application of iodine liniment.

*Present condition.*—He presents the appearance of a man originally of good muscular frame, but now considerably emaciated, and he states that he is still losing flesh. His complexion is of a markedly earthy tint, but without the slightest jaundice; the conjunctivæ are quite natural, and the urine clear. His skin is harsh and dry, the tongue coated, and digestion impaired. The left lung generally is unduly resonant on percussion as compared with the right; a few scattered râles are audible at the bases; and dry

sonorous rhonchi at the upper portion of the chest, especially towards the left apex. The expectoration is moderate, clear, frothy, and somewhat viscid, but never tinged with blood; cough is occasional, but not great. The heart occupies, apparently, its natural position; its rhythm and sounds are normal. The pulse is full, soft, and slightly quickened. The area of hepatic dullness is very markedly increased, extending from about the upper border of the fourth rib in the right mammary line to upwards of two inches below the umbilicus; in the mid-axillary line from the lower border of the fifth rib to three inches above the right crista ili. Upon placing one hand posteriorly, and the other over the anterior face of the liver, the antero-posterior depth feels greatly increased, yielding a sense of resistance. The entire right lobe on its anterior face felt tolerably firm and smooth, without any particular bulging or sense of fluctuation at this time, and, from its perfect painlessness and absence of tenderness on pressure, rather suggesting the idea of amyloid enlargement. The enlargement has a remarkably square end to the left of the umbilicus. The position of the organ remains unchanged during respiration, and is probably fixed, at least in places, by adhesion. The splenic dullness seems normal. Very marked oedema of both lower extremities exists. The patient continued in much the same state until Nov. 28th; the bronchitic symptoms were greatly lessened, but he complained of a "tight feeling" at the pit of the stomach.

Dec. 2nd: There was now apparent a marked and visible prominence over the middle of the enlargement, it being tense, elastic, with obscure hydatid fremitus on percussion, and a distinct feeling of fluctuation. Upon firm and sustained pressure over the prominence the fluid in the swelling seemed to be displaced, reappearing slowly with a rebound as the pressure was gradually relaxed.

Leaving for the moment these later physical signs it was necessary, in order to include all the data for accurate diagnosis, to look again into the past history of the case so far back as the supposed attack of flumbugo in 1875. For it is probable that this attack may have been connected with the development of a cyst deep in the liver, near its posterior surface; such a view seems consistent with what is known as to the ordinarily slow and painless growth of a hydatid cyst. Although no particular symptoms immediately followed the attack beyond a wandering pain in the back and impaired digestion, more remotely there occurred, without other obvious cause, gradual loss of flesh, change in the complexion, and, finally, oedema of the lower extremities, the latter result only to be explained by the pressure of a cyst upon the inferior vena cava, for the urine was fairly normal in quantity and free from albumen. Finally, the severe pain at the pit of the stomach, together with the rigors and the comparatively rapid development of the anterior fluctuating swelling, led to the diagnosis of a compound suppurating hydatid cyst of the liver.

Mr. Rose was requested to open the cyst by incision, which was done on Dec. 6th under the antiseptic spray, and the antiseptic treatment was continued unintermittingly throughout. All notes from this date were taken daily by Mr. Pollard. An incision, one inch and a half in length, was made just internal to the cartilage of the ninth rib, when a large amount of pus and hydatids escaped through the opening. The number passed at once, and by subsequent manipulation, was about five hundred. The hydatids varied in size from an ordinary pea, or smaller, to cysts whose walls were two inches in diameter. A large-sized caoutchouc drainage-tube was inserted and the wound dressed. In the evening severe pain of a shooting character was complained of. Pulse 100; temperature 98°6'. A quarter of a grain of morphia was administered.

December 7th: Wound dressed; free discharge of pus and hydatids; discharge more serous; drainage-tube left in situ; dressings tinged with bile; odour of sulphuretted hydrogen. Pulse 100; temperature, 98°.—8th: Wound dressed; discharge less free; hydatids tinged with bile blocking tube, which was removed and reinserted. Pulse 84; morning temperature, 98°; evening, 99°8'.—9th: Appetite good; feeling stronger and has less pain. Wound dressed; discharge of feculent odour, tinged with bile; tube removed, shortened, and reinserted. Salicylic cream applied round the wound. Morning temperature, 98°; evening, 99°4'.—10th: Some cough; wound dressed; free discharge of the same character. Temperature 98°.—11th: No discharge has come through the dressing; bowels acted for first time since operation. Morning temperature, 98°6'; evening, 97°2'.—12th: No dis-

charge has passed through; feels comfortable and free from pain. Morning temperature, 97°4'; evening, 100°; has slept through the rise.—13th: Wound dressed; drain blocked by cysts; four ounces of muco-biliary matter evacuated. Morning temperature, 98°; evening, 99°4'.—14th: Patient looking clearer and brighter; occasional darting pains in region of liver; complains of presence of the tube; wound dressed; free biliary discharge; fewer cysts. Morning temperature, 97°8'; evening, 98°.—15th: Discharge not through; no pain; looking and feeding well. Temperature, 98°.—16th: Wound dressed; discharge thicker and more grumous; still feculent odour; tube shortened; before reinsertion the dressing forceps had to be used, as the liver appeared to have risen somewhat. Morning temperature, 98°; evening, 97°2'.—17th: No discharge through. Temperature normal.—18th: Slight throbbing pain. Morning temperature, 97°4'; evening, 98°.—20th: Wound dressed; drainage-tube removed; slight serous discharge tinged with bile; free from pain; sat up; protective used for the first time.—22nd: Wound dressed; no special odour with discharge, which is serous, but the protection is blackened.—26th: Dressed; same character of discharge.—29th: Wound open to one inch depth; not much discharge; got up.

Jan. 1st, 1882: Dressed; less discharge, without smell; sinus about the same depth.—4th to 6th: Dressed; no smell detectable since Dec. 18th until Jan. 8th, 1882; temperature ranged between 97°4' and 99°; no hydatids were discharged; patient was up daily.—9th: More pain complained of; the discharge on dressing had again a feculent odour; six hydatids came away; dressed with salicylic cream, spray and deep dressings. Morning temperature, 98°2'; evening, 100°2'.—10th: Some pain complained of; expression of countenance evidently anxious; kept in bed.—11th: Still complains of pain; no change in respect of temperature.—12th: Morning temperature, 101°2'; evening, 98°6'; felt in the evening a rush of discharge from the wound; feculent smell detected two beds off; pulse full; headache; furred tongue.—13th: Incision reopened by inserting and opening drainage forceps; thirty or forty hydatids passed with about six ounces of pus of feculent odour. The cysts measured more than two inches and a half in diameter. The finger introduced detected a kind of shelf, behind which it entered a cavity deep in the liver. A large caoutchouc drainage-tube two inches and a half long was introduced, which, after passing upwards, dipped into the cavity. Morning temperature, 98°4'; evening, 100°.—14th: Dressed; a longer tube of four inches was introduced, the present tube being absolutely blocked by hydatids. The forceps were used and several more extracted, with four ounces of pus of feculent odour. Morning temperature, 99°8'; evening, 98°4'.—15th: Pain in wound less; looks brighter; discharge not through. Morning temperature, 98°; evening, 99°4'.—17th: Dressed; a larger tube introduced; six ounces of pus and more cysts discharged; it seems as if a large mother cyst had existed behind the first which was opened.—19th: Dressed; tube again blocked. A silver tube is to be made of such a size that it cannot be blocked, and will be capable of being cleaned without removing it.—21st: Dressed; pus to a large amount, and with decomposing cysts, escaped. Morning temperature, 100°4'; evening, 98°4'.—27th: Since the 21st the wound has not been dressed, as the discharge has not come through; temperature has varied between 98° and 99°4'; dressed to-day; discharge smelling less, and less abundant; drain shortened.—28th and 29th: Patient more comfortable; discharge not through. Morning temperature, 98°; evening, 99°.—30th: A silver drainage-tube with collar made specially, 6·5 centimetres long, collar 1 centimetre broad, calibre 1·4 centimetres; this was inserted after the removal of the previous tube. Its insertion was followed by a gush of a very large quantity of pus and hydatids, the sheets &c. being soaked in addition. During the night dressing and draw-sheets were soaked. Morning temperature, 98°2'; evening, 99°4'.—31st: Dressed; eight large cysts on dressing and in tube; discharge serous; air enters and is expelled during respiration through the tube, which is protected both by the spray and a piece of gauze dipped in carbolic lotion. Temperature, 100°2'.

Feb. 1st: Dressed; a copious serous discharge, which has coagulated round the tube. Morning temperature, 98°4'; evening, 99°4'.—2nd: Dressed; discharge serous, thinner; no cysts. Patient complains in the evening of the pressure of the tube. Morning and evening temperature, 98°2'.—3rd: Brown serous discharge; tube projecting half an inch;

collar protected by wet gauze, and protective with salicylic cream.—4th: Dressed as yesterday.—5th: Dressed. Night temperature, 101°. Bowels not open for several days; purgative.—6th: Discharge not through. Morning temperature, 98.4°; evening, 99.4°.—7th: Dressed; tube kept half an inch out; serous discharge.—8th: Dressed. If the dressing over the tube is touched much pain is felt, and patient feels as if "something was forcing out the tube."—12th: Dressed; much less discharge; tube in only two-thirds of an inch; well padded with wet gauze.—15th: Dressed; tube forced out; little discharge; liver dullness nearly normal; silver tube finally removed.—17th: Dressed; superficial wound dressed with protective and gauze with collodion to keep it impervious. Patient got up.—23rd: Granulations prominent; probe enters a quarter of an inch, touched with nitrate of silver and dressed with dry gauze and collodion.—26th: Wound healed; covered with collodion; since Feb. 1st the temperature, except on two occasions, has not risen above 99° or fallen below 98°. The patient is now able to go out, and seems quite strong again.

April 9th: The patient expresses himself as perfectly well, and leaves the hospital to-morrow for a convalescent home. He has gained appreciably in weight; his face has again filled out, and the complexion is natural. Both appetite and digestion are now excellent, and every function is naturally performed. The liver has retracted nearly within its normal limits, some slight sense of resistance being still detectable. The shape of the abdomen is quite normal. It may, therefore, be fairly hoped that the cure will remain permanent.

*Remarks.*—The case was probably one in which two hydatid cysts were developed in the liver; the larger and earlier commencing deep in the right lobe, occupying the middle and posterior portions, and eventually communicating with the anterior cyst, which latter, judging from the history of the case and the late appearance of visible bulging, seemed to be of more recent formation. This, at least, may be regarded as the probable order of development, inasmuch as the finger, after passing through an apparent anterior cyst, entered a well-defined opening at its further end, barely admitting it (and which, judging from the thickness and the resistance of the walls, appeared to consist of healthy hepatic tissue), and leading into another cavity, the exact extent of which could not be accurately gauged, but, judging from its contents, seemed to be of very considerable size, sufficient to exert pressure upon the inferior vena cava, and to induce secondary dropsy of the inferior extremities. It will have been noticed that on several occasions during the progress of the treatment discharge of bile took place through the tube. Some biliary duct or ducts had evidently opened into the cavity. Although several of the cyst membranes were stained with bile, large numbers of hydatids were subsequently discharged at intervals apparently quite unchanged, retaining their tense and semi-translucent appearance, seemingly tending to show (contrary to what is usually supposed) that the bile during this period had neither excited inflammation nor exercised any lethal influence over the parasite. In many of the secondary cysts that were entire numerous minute buds studded the germinal membrane, to which they were more or less firmly attached. Such of the undamaged cysts as were microscopically examined contained either hooklets or echinococci. Some cysts were passed ruptured and decomposing. The feculent odour was tolerably persistent, more or less detectable in the discharge through the tube, and probably resulted from the proximity of the mother cyst to the intestine, as usually happens wherever pus forms near the latter; or from some change in the character of the cyst contents. At no period did there exist the slightest ground for supposing that any communication with the bowel existed. If there were, it must have been a mere capillary fissure. In conclusion, it may be observed that considering the high mortality of cases of suppurating hydatid cyst of the liver, treated heretofore by incision in the ordinary way, the advantages of the antiseptic plan are clearly manifest.

P.S.—May 2nd: The patient has returned from the country in excellent health, and is about to resume duty as a constable.

## ON CONVULSIONS IN CHILDREN.

BY EUSTACE SMITH, M.D., F.R.C.P.,

PHYSICIAN TO HIS MAJESTY THE KING OF THE BELGIANS, PHYSICIAN TO THE EAST LONDON CHILDREN'S HOSPITAL AND THE VICTORIA-PARK HOSPITAL FOR DISEASES OF THE CHEST.

THE commotion in the nervous system which goes by the name of eclampsia, or a fit of convulsions, is a common phenomenon in infancy, and is sometimes seen in early childhood. It depends upon an exalted sensibility of the reflex centres seated in the pons and the medulla oblongata, but is attended by no change in those parts capable of being detected on examination of the dead body. The disturbance is essentially a symptom, and may be produced by a variety of causes. Irrespective, then, of the immediate danger to life, the phenomenon may be of serious moment or of trifling consequence, according to the cause which has induced it. It is therefore of great importance to ascertain its mode of origin, for only by this means can we speak with any confidence as regards the influence which the attack is likely to have upon the future well-being of the child.

It is during the first two years of life that the tendency to this form of nervous derangement is most active. At this period of childhood the nervous system of the infant, although immature, is undergoing rapid development, and the reflex centres respond briskly to every form of peripheral irritation. The tendency to eclampsia is not, however, confined to this age. Convulsions may even affect the infant in the womb. Early death of the fœtus and premature labour can be sometimes attributed to this cause, and it is to this accident that some varieties of congenital deformity have been referred—those which are characterised by permanent contraction of special muscles. After birth the proneness to convulsions may continue for a longer or shorter time, according to the natural sensitiveness of the nervous system to external impressions. It is therefore much more persistent in some children than in others, and may endure in exceptional cases to the ninth or tenth year.

There are certain conditions which predispose a child to convulsions. Thus, the liability to eclamptic seizures sometimes runs in families so that all children born of certain parents are found to suffer from these attacks. In other cases the tendency is confined to certain individuals of the family, or even to one sex. Thus, all the boys may have convulsions, while the girls escape. Again, in rickets there is a special convulsive tendency, which is very remarkable; and a very large number of the cases of reflex convulsions are found in children with this constitutional condition. When the predisposition exists, very slight causes—causes often so trifling as to escape recognition—may induce the attacks.

Within certain limits, the state of a child's nutrition does not appear to affect his susceptibility to convulsive seizures. A strong child and a weak one may be equally prone to suffer from this nervous disturbance. When, however, an infant is greatly reduced by long-continued interference with nutrition, a remarkable difference is noticed in his sensibility to nervous impressions. Not only is there no exaltation of reflex function, but the normal excitability of the reflex centres is diminished or annulled; so that in a child so enfeebled convulsions are seldom of reflex origin, but usually indicate grave cerebral disease.

In every case of convulsions we should examine the patient very carefully for signs of disease of the brain or its membranes; more especially as the first question usually asked by the parents, after their excitement and alarm have somewhat subsided, relates to the possibility of any affection of the brain. In infants of twelve months of age and under—if the child be fat and robust-looking, the fit is in all probability reflex; if he be under-nourished, weakly, and wasted—i.e., in that condition where all reflex excitability is practically in abeyance, the convulsion is no doubt the consequence of an intra-cranial lesion. In a weakly emaciated infant by far the most common cause of a convulsive seizure is general tuberculosis with secondary tubercular meningitis.

The character of the fit itself will give some indication. Cerebral convulsions are often partial; therefore if the spasms are limited to one side of the body, or to one limb, we should search carefully for signs of cerebral disease. Paralysis of

THE Société contre l'Abus du Tabac offers a prize for the best essay on the question, "Do there exist characteristic symptoms sufficient to warrant the conclusion that amaurosis or defect of sight is caused by the excessive use of tobacco?" The prize consists of books to the value of 200 francs and a bronze medal.

the face remaining after the end of an attack is indicative of a cerebral lesion. Thus, drawing of the mouth to one side, ptosis, or inequality of pupils are symptoms never seen in true uncomplicated eclampsia. A squint persisting after the convulsion has passed off must be regarded with anxiety; for although not necessarily a grave symptom, it is often indicative of a serious lesion, and if accompanied by signs of heaviness or tendency to stupor, must be looked upon as of unfavourable omen. Again, convulsions, general or partial without loss of consciousness, should lead us to suspect disease of the brain. Another important sign is the condition of the child after the attack. In true eclampsia consciousness is recovered quickly after the seizure; and if any drowsiness remain it is over in a few hours. Signs of persistent stupor or dulness of the senses would point to a cerebral lesion. Mere temporary loss of power in a limb is no proof of centric origin; but if the paralysis continue longer than a few hours, or a day or two, especially if contraction of muscle occur, we may conclude that some centric lesion, either primary or secondary, is present. Even if the convulsion leave behind it conclusive evidence of a cerebral lesion, it does not follow that the lesion was the cause of the fit. One consequence of eclamptic seizures is congestion of the brain; and if the nervous attack be prolonged, serous effusions and perhaps minute capillary hæmorrhages may occur and lead to very serious consequences.

Convulsions taking place at the end of the exanthemata and other febrile diseases are commonly attributed to cerebral congestion, although it seems probable, from the observations of Dr. Bastian, that embolic plugging of minute cerebral arteries takes a large share in their production. These attacks never come on except at an advanced period of the illness, when the state of the patient is evidently very serious, and they quickly terminate his sufferings. It must be remembered that a fit may be the first sign of secondary tuberculosis. Tubercular meningitis, when it occurs in the course of an acute illness, has its own early symptoms masked by those proper to the primary disease, and only reveals its presence by the more violent phenomena which are characteristic of the third stage of the intracranial lesion. Appearing in this form—as a part of a general formation of the grey granulation all over the body—tubercular meningitis is not uncommon in babies of a few months old. If, then, in a child of any age, suffering from an acute inflammatory disease, such as an attack of catarrhal pneumonia, convulsions come on, we should strongly suspect tuberculosis, and if the fit is followed by squinting and irregularity of pupils, with or without rigidity of joints, we can speak confidently of the existence of tubercular inflammation in the skull cavity.

In cases where no serious cerebral lesion is suspected, it is important to distinguish an eclamptic attack from an epileptic seizure. At the time this is impossible, for the state of the patient requires all our attention, and, if only to quiet the alarm of the relatives, it is urgent that something should be done. When, however, the subsidence of the spasms gives us leisure to make inquiry, we should try to discover some source of irritation to which the convulsion may be attributed. We should look for signs of rickets—the condition which especially predisposes to eclamptic seizures—and inquire for any convulsive tendency in the family. The age is of importance. Up to the time of completion of the first dentition the disturbance is probably not epileptic, and if the gums are tense and hot, or the child has lately swallowed some unsuitable food, we may feel satisfied that the case is one of pure eclampsia. Again, high fever is not a characteristic of epilepsy, therefore if there be pyrexia the fit is probably reflex, or is a nervous disturbance announcing the onset of one of the exanthemata, or of an acute disease. But irrespective of these considerations, under the age of two years epilepsy is rare, while reflex convulsions and the other forms of pure eclampsia are very common.

In older children it is more difficult, often it is quite impossible, to exclude epilepsy. If, however, the fit is a prolonged one, and lasts for an hour or more without intermission, we may conclude that the attack is eclamptic; for the duration of an epileptic seizure rarely exceeds ten minutes, or at the most a quarter of an hour. When the urine can be obtained it should be always examined for albumen, as uræmic convulsions in children are not uncommon. For the same reason the whole body should be carefully inspected for signs of peeling of the skin, as uræmic convulsions towards the end of the desquamative stage of scarlatina are far from rare. The attack of scarlatina is sometimes so mild

as to be overlooked by inattentive or unobservant parents; and even if it be known to have occurred the past illness may be looked upon as immaterial to the present disturbance, and may not be referred to. In all cases we must remember that after the age of three, or at the most four, years eclamptic attacks from reflex irritation are rare. Convulsions occurring in a child of this age, if not due to cerebral disease, are generally either uræmic or are premonitory of some acute febrile disease.

As long as any cause can be discovered for the attack the fit is probably eclamptic. It is the convulsion occurring without evident cause which is so suspicious of true epilepsy; and if a child of four or five years of age or upwards be visited while in apparent health by such a seizure we are justified in fearing the beginning of epilepsy. It must not be forgotten, however, that convulsive seizures at first eclamptic may pass into true epilepsy. There is no doubt that this does happen in cases where there is a strong neurotic inheritance. Where there is no such predisposition I believe that epilepsy only follows in cases where the eclamptic attack has induced a secondary cerebral lesion. In such a case, although the first attack, or series of attacks, may have occurred as a result of some appreciable cause, the after convulsions may arise without anything being discovered to serve as an explanation of the morbid phenomenon.

(To be concluded.)

## ON THE METHOD OF OPERATING IN STRANGULATED UMBILICAL HERNIA.

By RUSHTON PARKER, B.S., F.R.C.S.,  
PROFESSOR OF SURGERY IN UNIVERSITY COLLEGE, LIVERPOOL.

THE communication of Mr. T. F. Chavasse in THE LANCET of May 27th, 1882, is deserving of criticism on several grounds, among which are, the importance of the emergency, the principles concerned in its appreciation, and the question, above all, of practice. The gravity of a condition which, without artificial relief, is almost necessarily fatal, and which formerly seldom proved otherwise, in spite of that relief, cannot possibly be over-estimated; and the traditional importance of the emergency may have not been diminished by the comparative infrequency of its occurrence; may rather, as I think, have been enhanced, seeing that a possible reduction in the mortality may have failed to attract a deserved attention, through sheer poverty of the associated statistics. The amenities of experience (or of what, in default, has to do duty for it) sometimes uttered in the terms "he will never get better," or "such cases always die," are frequently more authoritative than trustworthy; and I confess that I have on that account now and then withheld the complete respect accorded by some to this familiar but despondent wail. In short, the frequent former fatality that attended herniotomy, as performed for umbilical strangulation, has never caused me to view it as the inevitable, or even as the most likely, prospective issue of such cases. But, after all, this statement of my impression must, like that of Mr. Chavasse, or of anyone else, be held subordinate to the great realities, in the light of which the mere impression may be criticised, and eventually justified or rejected.

The former death-rate of umbilical herniotomy, though absolutely high, has been in certain groups of statistics, especially in the hospitals of towns, almost if not quite equalled by that of inguinal and femoral. But an improvement has taken place all round, for reasons that will be differently explained under varying or imperfect impressions. It is certain, however, that of late years an immense immunity from death, in quarters where escape was previously more rare, has been enjoyed after the more common herniotomies; while there are records of conspicuous, if not numerous, successes in even umbilical cases. Much of this success is attributed, and fairly attributable, to the direct protective influence of the antiseptic system and the simplification and multiplication of its cures. But an indirect result of this success has been the removal of unwonted reluctance and delay; in fact men operate earlier, and for some purposes oftener, than they did before, while operations are freely undertaken that were formerly avoided altogether.

The causes of failure, and the means to ensure recovery, in cases of strangulated hernia are not all, however, summed up in the methods employed at the wound or hernial sac, since we have often to reckon with widespread disturbance of intestinal function, to administer opium and proscribe diet, for want of which precautions the most perfect herniotomy, or the most successful taxis without operation, may alike be rendered useless.

I had occasion to cut an umbilical hernia for the relief of strangulation in the summer of 1879. The symptoms were quickly relieved, and the patient made a simple recovery. A complication subsequently arose in the establishment of a faecal fistula, which did not heal spontaneously, but which I effectually closed at a second herniotomy in the summer of 1880. The case is recorded in the *Medical Times and Gazette* for Feb. 18th, 1882, where details are given. A radical cure of the hernial protrusion did not occur (though I attempted it at the second operation), owing to the wideness of the neck, the thickness of its margin, and the inability of my sutures to obliterate the aperture. But the method that proved unsuited to mine succeeded in a case of much larger umbilical hernia, but with a smaller neck, previously operated on by my colleague, Mr. Banks, for the purpose of radical cure alone, and at which I assisted him, in the same summer.<sup>1</sup> Eventually I was enabled to radically cure, by effectually ligaturing the sac alone as deeply as possible, an irreducible omental umbilical hernia,—a method I venture to recommend to all for simplicity and safety.<sup>2</sup>

I can see nothing in umbilical hernia, strangulated or not, to which the known principles of surgery that apply to other herniæ do not equally apply; still less do I see why such a hernia should be, under any circumstances, denied complete reduction, or the supreme advantage of a radical cure. Neither can I imagine that the three patients in these four cases were placed in special jeopardy by manipulation, under suitable precautions, of the umbilical sac or of its contents; or that their simple and speedy recovery can be viewed in the light of a narrow escape.

It is true that in only one instance was strangulation present, and even then of so mild and recent a character as to contrast favourably with similar cases more advanced. But the very fact that the woman was not left till she became moribund, or rather was promptly rescued before signs of actual danger were evinced, is one of the proofs so often and so truly adduced that we must not mistake for consequences of the operation symptoms that never occur when herniotomy is properly and promptly performed. Perhaps one cause of the desperate state into which intestinal irreducibility may drift, in umbilical cases, is the comparative wideness of the neck, facilitating descent, but not strangulation, which is consequently rather prohibited, and, what is worse, is from its more gradual onset apt to be insufficiently noticed by the patient, who fails to connect with the tumour, not differing, perhaps, from its usual daily state, the uneasiness, cructation, and other early symptoms, so much more appreciable to some non-medical intelligences than to others, and so instantly attractive of medical notice. It is truly bad enough for the patient if medical attention be delayed until the unequivocal strangulation has reached an advanced stage of constitutional and even local disturbance. Precisely the same, however, occurs in old inguinal herniæ, from many of which an umbilical differs only and simply in the single item of locality. Even at this juncture the successful advantage of operation is conspicuous enough, but it may go very hard with the patient if his surgeon has to think twice about cutting him, through a perfectly unfounded and superstitious dread of killing, by the means alone capable of keeping him alive. I cannot therefore entertain or further discuss the notion of the special vulnerability of the sac of a strangulated umbilical hernia as distinguished from that of the adjacent peritoneum; the onus of proof rather rests upon those who have invented the idea, which, I venture to think, is not based upon any intelligible principle of anatomy, physiology, or clinical experience. It is at best, and under the easiest circumstances, a roundabout way of attaining what should be a straightforward, intelligent, and even simple end; in gangrenous cases it is the surest way to spill seæ into the peritoneal cavity, while in all it is an obstacle to radical cure, without which no herniotomy can now be said to be artistically complete, and to solely attain which many herniotomies are very properly undertaken.

## SYPHILIS AND MARRIAGE.<sup>1</sup>

By FREDERICK W. LOWNDES, M.R.C.S. ENG.,  
SURGEON TO THE LIVERPOOL LOCK HOSPITAL.

THE following case will serve as a very appropriate introduction to this paper, as well as affording ample reasons for introducing this subject:—In October, 1879, I was requested by our respected honorary member, Mr. F. Worthington, now retired from practice, to see for him a married woman in the last stage of tertiary syphilis. She was in a dying state at the time of my visit, and it would be difficult to convey any idea of the shocking condition in which I found the poor creature, though it may be imagined what it must have been from the subsequent history of her case. The greater portion of her face was gone, her sight was gone; it was with the greatest difficulty that she was fed, and the stench which filled the room was the most sickening I ever encountered. I only saw her once, as she died two days after my visit; and I may here remark as worthy of notice, that her friends were most anxious that the cause of death should not be stated in the certificate, fearing that such would entail a forfeiture of the club money. Circumstances prevented me from taking some medical friend to see the case as I could have wished, or from getting any complete history of it until recently, when, at my request, Mr. Worthington sent me the following details:—

"I cannot," he writes, "find my notes of the case of Mrs. T—, so that I cannot give you more than my recollection of her unfortunate case. Her husband was a sailor and married her when she was seventeen or eighteen. He had had a chancre, and said that a surgeon pronounced him to be thoroughly free from all disease, and that there would not be any risk of infecting his wife if he married. Mrs. T— suffered from syphilis some months after the marriage, and subsequently she was for some months in one of the London hospitals. She came out not much better. She had been under the treatment of two medical men in Liverpool and of Mr. Bickersteth before I saw her. The people in the house in which she lived neglected to carry out Mr. Bickersteth's directions, and he consequently declined having anything more to do with the case. She was then under another surgeon's care for a time. When I first saw her there was necrosis of both the upper and lower jaw. I removed at different times the greater portion of the upper maxillary bone, extending up to the eyelid on the right side. As you know, she was emaciated to a great degree, and could scarcely swallow for some time before her death. Her husband was in the navy, not a common sailor, but what office he held I do not know. He assured me that a surgeon pronounced him perfectly well and safe in marrying. It was the worst case of tertiary syphilis I ever met with; the smell was so horrible that the room was intolerable without the unintermitting use of disinfectants."

I took great pains to find the missing links of this history, and especially that portion of it which referred to treatment in a London hospital. Here I was unsuccessful. St. Bartholomew's, University College, Middlesex, and the Female Lock Hospitals were each indicated as the one in which Mrs. T— was treated, but at none of them could I obtain any information of her. From the landlady of the house in which she died I learned that the deceased had one child which only survived its birth a few months, and was very weakly; also that both the deceased and her sister were always delicate women. She added that Mrs. T— preserved her bearing up to the last, and to a great extent her reason, which only wandered occasionally.

This case suggests very grave reflections. Here was a man knowing that he suffered from a disease which might prejudice his marriage, taking the precaution of seeking medical advice and obtaining medical sanction for it. It would have been interesting to know what interval elapsed between the healing of the chancre and his marriage, as also whether he was treated with or without mercury. It is true that the frightful result was the consequence of a delicate, probably scrofulous constitution, and of neglect as much as of syphilis. It is also probable that under different and more favourable circumstances the deceased might have re-

<sup>1</sup> Abstract of a paper read at the Liverpool Medical Institute, April 20th, 1882.

covered. Still the fact remains that she suffered from syphilis very shortly after her marriage, and that this was the primary cause of her death. It may be urged that this was a very exceptional case. So it was; but it is not generally recognised that the worst cases of tertiary syphilis occur, not among prostitutes, nor the male patients of lock hospitals, but among respectable married women. In September, 1875, I saw in the London Female Lock Hospital a married woman who was the subject of extensive tertiary disease of the bones of the face. She was also covered with rupia; and in spite of the most liberal use of carbolic acid and ample ventilation the stench was intolerable. I subsequently learned, from the able and courteous resident surgeon, Mr. G. H. Bishop, that after a stay in the hospital of over two years all the necrosed bone was removed and a firm cicatrix covered the parts, the nose, mouth, and right eye being one cavity. He adds: "I have a case of extensive necrosis of the skull, the brain protruding in several places. This, again, is a respectable married woman." Fournier, in his recently published work, says,<sup>2</sup> "Every married woman who contracts syphilis under the conditions which we have considered will always be very insufficiently and incompletely treated, and will consequently be exposed to the most serious future dangers. . . . I insist upon it, that nothing is more frequent in practice than tertiary symptoms of syphilis contracted by women in marriage. Such observations are most abundant; I can reckon them by hundreds in my hospital and private notes."

During the last seven years between seventy and eighty married women have been admitted into our lock hospital here, a large number when we consider that there are only two wards opening into each other, in which married women and prostitutes are mixed together, a fact calculated to deter the former from coming in at all. Of these the greater number suffered from syphilis, some having the tertiary form very severely.

Now, it is no less remarkable than true that those men who may with perfect safety marry, never having had syphilis at all except in their own imaginations, are those who are the most anxious and dubious about doing so, consulting their own and other medical advisers, and being with great difficulty persuaded that there is no danger in their marrying. On the other hand, those who take no medical advice on the subject are too often the very ones who ought to do so, taking the irrevocable step of marrying within a recklessly short period of having suffered from syphilis, or even before its primary manifestation has quite disappeared. Hence it follows, naturally, that many married women suffer from syphilis, and suffer very severely, the approach of the disease being to them insidious and mysterious, occasioning great reluctance to seek medical advice until much valuable time has been lost.

A man comes to consult us. He says he is going to be married in a few days, that he has had impure connexion very recently, and he wishes to have some prophylactic against any disease he may have contracted. On examining him we find no disease whatever. But we all know that the period of syphilitic incubation is one of weeks rather than days, and instances of seven, and even eight, weeks have been proved beyond doubt. This is not a mere point of theoretical interest, but one of great practical importance. Although our patient may be perfectly healthy apparently, he may, nevertheless, have syphilis incubating in him, and a few weeks will suffice to remove all uncertainties. Hence, it is manifest that the only prophylactic we can safely prescribe is a postponement of the marriage for at least three months from the date of impure intercourse. I am unable to give any case in my own practice showing the disastrous results of this recklessness, which is much too common; but a very good illustration is given in Fournier's work, under the note "Syphilis contracted before marriage, and developing itself afterwards."<sup>3</sup> The result of the case is thus summed up:—

1. Coitus a fortnight before marriage with a woman afflicted with valvular syphilides.
2. Marriage in full state of health.
3. A fortnight after marriage the appearance of a syphilitic chancre, followed at the usual time by general symptoms.
4. Infection of the young wife by the husband's chancre, the nature of which was misunderstood when it appeared.

Sometimes we are consulted by men with sores on the penis who are about to be married in a few days. Obviously, marriage is out of the question, and must be adjourned *sine die*. I should not think it necessary to say this if I had not seen such cases, and found it very difficult to dissuade at least some men from marrying in such a condition.

But the most frequent and far the most anxious cases are those of men who have undoubtedly suffered from syphilis more or less recently, sometimes being under our own treatment, and who wish to know whether they can safely marry. These cases present grave difficulties, and involve us in very serious responsibilities. We are between two fires. On the one hand, nothing could be so terrible as to incur the responsibility of such a case as that I cited at the beginning of this paper, or, indeed, to sanction any marriage which might result in the syphilitic infection of the wife, in however mild a form. On the other hand, to forbid marriage upon what may afterwards turn out to have been insufficient grounds would be to incur a responsibility only secondary to this. It is generally admitted that no disease is so amenable to treatment as syphilis, and, therefore, the fact of a man having had syphilis does not of itself constitute a bar to marriage. Fournier gives the following as the conditions under which a man who has had syphilis may marry:—

1. Absence of actual specific symptoms.
2. Advanced age of the diathesis.
3. A certain period of absolute immunity since the last specific manifestation.
4. The non-menacing character of the disease.
5. A sufficient specific treatment.

He also gives notes of eighty-seven cases of men who, having suffered from syphilis, married, and subsequently became fathers between them of a total of 156 children absolutely untouched by the disease, and in thirty-five of these cases various symptoms of an unquestionably specific character developed themselves after marriage, without the wives or children of these patients in any way being affected by the disease. While admitting the reassuring aspect of this latter fact, he very properly warns us not to exaggerate its bearing nor to strain it to mean more than it really does.

By the term sufficient specific treatment he explains his meaning to be that mercury and iodide of potassium are to be administered in really active and curative doses, intermittently for at least three or four years. Even then he advises delay before marrying, but gives his consent if the patient has gone on for eighteen months or two years without symptoms, and if he be otherwise in good condition. Mr. Jonathan Hutchinson, who writes the preface to the English translation, says:—"I feel scarcely prepared to go the full length which M. Fournier suggests in the direction of caution and prohibition. . . . Respecting a malady so common as syphilis, whilst it is often our duty to warn, it is also not unfrequently equally our duty to encourage." With this most of us will agree, but I must express my regret at the following sentence of Mr. Hutchinson's: "The surgeon who, on account of past syphilis, forbids marriage to an otherwise eligible man, must remember that he forbids it at the same time to some woman who possibly, if well informed as to her risks, would willingly encounter them." Now, I maintain that no woman should be permitted to encounter such risk, and neither man nor woman is justified in exposing to this risk an unborn child. It seems to me that each case must be judged on its own merits. When the constitution is good, and there has been sufficient specific treatment, marriage may be permitted within a much shorter period than M. Fournier suggests, and with safety. Syphilis alone, and syphilis combined with scrofula, are two very different foes to contend with; and if our patient be of a scrofulous temperament, a delay even longer than M. Fournier's may be desirable. In all doubtful cases we shall do well to seek consultation with one another, specialists consulting freely with all-round physicians and surgeons, and with obstetricians. This should be done to avoid specialism becoming narrow and routine, especially when we remember how that syphilitic diseases penetrate through every nook and cranny of medical, surgical, and obstetrical practice. I have been frequently urged to try non-mercurial treatment, but have always been deterred from doing so by the words of the late Dr. Thos. Edward Beatty, a pupil, be it remembered, of Richard Carmichael, in his address at the annual meeting of the British Medical Association, at Leeds, in 1869: "Mercury given to the man when first diseased would, I

firmly believe, have prevented this terrible calamity—i.e., the syphilitic infection of the wife; and I would now humbly suggest to all who undertake the treatment of venereal disease, that if they have a certainty that their patients will remain celibate all their lives, they may heal up their sores and dispel their eruptions and sore throats in any manner they like; but that they have no right to expose the pure, innocent, high-minded females of society to contamination by marrying men treated without mercury."

## A CASE OF TRANSPOSITION OF HEART.

By CHAS. POPE, L.R.C.P. & L.R.C.S. EDIN.

G. C—, a bricklayer, aged forty-one, was admitted to the South Shields Workhouse Hospital on May 24th, 1882, suffering from pneumonia with distressing dyspnoea and extreme lividity. The heart's impulse could not be detected anywhere on the left side of the sternum, and the sounds on auscultation were distant and muffled. On examining the right side I found the impulse well marked about two inches below the right nipple and two inches on the right of the sternum. On auscultation at this point I heard a mitral regurgitant murmur, which, however, was only audible over a very limited space, about two inches in diameter. It could not be heard in the axilla nor at the lower angle of either scapula. The pulsations could be heard feebly at the back of the right chest low down, but were inaudible at the back of the left. I could obtain no history of pleurisy, empyema, or pericarditis, neither was there any evidence of tumour of any description, the man declaring that until the present he had never had a day's illness in his life. He had always been a hard worker and a good deal addicted to drink. Under the circumstances I was driven to the conclusion that this was a case of transposition of heart.

The patient died on June 4th, and on the following day, assisted by Mr. Robson, I made a post-mortem examination. On opening the thorax we found the heart natural in size and weight, but nearly entirely on the right of the median line, as indicated during life. The aorta ascended to the central part of the thorax, after which it arched at the usual level over to the left, and descended on the left of the vertebral column, giving off in their normal position its three large branches; these were distributed as usual. The pericardium was nowhere adherent. On opening the left side of the heart the anterior flap of the mitral valve was partially adherent to the endocardium, as were also some of the chordæ tendineæ, thus preventing its proper closure, and giving rise to regurgitation; there was also slight fibrous thickening. The tricuspid valve was in every respect normal, but the right side of the heart was full of clotted venous blood. The lungs in appearance and on section presented the usual signs of grey hepatisation; the right lung was markedly smaller than the left, but consisted of three lobes; the left lung consisted of two lobes as usual; there was no fluid in the cavity of the pleura, nor were there any pleuritic adhesions. On opening the abdomen the liver was found in its natural position and healthy, as were all the other organs. This was evidently a case of congenital abnormality.

South Shields.

## DISLOCATION OF THE LOWER END OF THE TIBIA FORWARDS OR OF THE FOOT BACKWARDS.

By GEO. ASHMEAD, L.R.C.P. & L.R.C.S. EDIN.

ON the evening of June 11th I was sent for in haste to the house of an ironworker, who was said to have broken his leg. I found him lying on the sofa with his left leg resting upon its fellow; he was groaning with pain, and on examination I found the lower end of the tibia occupying a position on the instep of the foot; the extensor muscles and the integuments were tightly distended and of a rose-red colour; the toes pointed downwards and the heel drawn upwards. The fibula was fractured near the articulation. By securing the knee and extending the foot with slight flexion on the

tibia, reduction was easily effected without the aid of an anæsthetic, accompanied by a grating sound distinctly audible to those present. Instant relief followed replacement; the foot was bandaged and light lateral splints applied. The easy reduction may be ascribed to the early attendance, the injury having taken place only a quarter of an hour previously. The above is the only example I have met with, and is described by Bryant, Hamilton, and others as extremely rare. Some surgeons have found it very difficult of reduction. The patient had a pair of heavily nailed boots on, and slipped upon some wet glazed bricks, his leg being doubled under him, "tailor fashion," to use his own words. Brierley Hill.

Nulla autem est alla pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

## MIDDLESEX HOSPITAL.

CASES OF SARCOMA.

(Under the care of Mr. J. W. HULKE.)

CASE 1. *Sarcoma beneath the Superficial Muscles of the Calf of the Leg; Excision; Recurrence; Amputation; Secondary Hæmorrhage; Death.*—A cook, aged sixty-nine, was admitted into Regent ward on April 26th, 1880, with a swelling in the right leg, which she thought had begun six years previously. Latterly its growth had been rapid, and it had become very painful. The swelling was caused by an elastic, lobulated mass, reaching from near the heel half-way to the ham. When the leg was extended the mass appeared fixed, but when the leg was flexed, and the superficial muscles of the calf were relaxed, the mass was found to be so movable as to preclude the idea of its being attached to periosteum and bone. Amputation being rejected by the patient, on May 5th it was cut out by a long incision, splitting the gastrocnemius and soleus. It was found to be beneath the fascia covering the tibialis posterior muscle. The posterior tibial artery passed into the tumour, and was necessarily cut away with it; the posterior tibial nerve, which was stretched over its surface, was disengaged from it and saved. The wound was washed out with a chloride of zinc solution, and dressed with boracic lint, and the limb was slung. Healing was slow, as might be expected at the patient's age, and in so extensive a wound, and was not completed till the end of July.

In the following October the patient was readmitted with a recurrence of the tumour. There was now above the inner malleolus a mass of the size of a small orange. The skin over its summit was gangrenous, and for some space around it was inflamed. She complained of much pain in the foot, and plaiting it on the ground caused spasmodic flexure of the leg and foot. Amputation, previously rejected, was now sought by the patient, and on Oct. 13th, the limb was removed by Teale's method, below the knee. The vessels were secured with carbolised catgut ligatures. At the end of one week she had very severe hæmorrhage from the stump, from which she never rallied, and died eight hours later. The primary and recurrent tumours were spindle-celled sarcomata.

CASE 2. *Sarcomatous (?) Tumour of Scapula; Secondary Affection of the Lungs.*—A housekeeper, aged forty-four, was admitted into Regent ward in September, 1881, for a tumour of the right shoulder-blade. It was an oval mass, of the size and figure of a cocoa-nut cut lengthwise, firmly attached to the scapula. Its surface was even and defined, and the skin over it was free. It was not tender when handled, but occasioned severe pain, radiating into the neck and down the arm. The grasping power of the right hand was less than that of the left, and the hand felt numb. No enlarged glands could be felt in the armpit. Her breath was short, and she had a cough. She attributed the origin of the tumour to a fall five months before, and she said that it had grown from the size of a walnut to its present bulk during

the last month. Dr. Cayley, who examined the chest, found dullness of the right side from the collar-bone to the level of the fourth rib, and thought this due to secondary tumour growth. She remained in the hospital for six weeks, during which time the tumour on the shoulder and the pulmonary complication both made great progress. She was allowed to go out with an "exeat" for a few hours, and did not return.

**CASE 3. Large Periosteal Sarcoma of the Upper Arm (Pregnancy); Excision; Recovery.**—A remarkably fresh-looking well-grown maid-servant, aged twenty-two, was sent into the hospital by Mr. Pitts of Chelmsford on July 1st, 1880, for a tumour of the arm, of the presence of which she had only very lately become aware, a fellow-servant having noticed the swelling whilst she was washing, and called her attention to it. The tumour reached from near the shoulder to midway between this and the elbow, forming a very conspicuous swelling of two principal and some smaller lobes. The largest of these was beneath the triceps muscle at the back of the humerus. Another large lobe passed round the inner side of the humerus, pressing out of their course the nerve-cords and large vessels to the front of the bone beneath the biceps muscle. It was thought that the mass was slightly movable on the bone. Its consistence was very soft and elastic. It was not tender when handled, nor, usually, painful, but there were occasionally shooting pains in the distribution of the musculo-spiral nerve. The girth of the arm over the tumour was fourteen inches, that of the other arm at the same level ten inches. The principal mass of the tumour was laid bare by a long incision through the middle of the triceps. It was crossed superficially by the trunk of the musculo-spiral nerve, which it had lifted from its groove. This nerve, with the brachial vessels and nerves at the inner side of the arm, were disengaged, and the tumour was dissected out. It sprang from an oblong spot, one inch and three-quarters in extent, of the periosteum at the upper and back part of the humerus. This part of the bone being found rough after separation of the tumour, was cut away. Except at its attachment the tumour was completely invested with a capsule of dense connective tissue. The wound was washed out with a solution of zinc chloride, and four deep rubber drainage-tubes inserted. Strict Listerian measures were adopted during the operation and the subsequent dressings. On the following day the temperature was 100° F., and the pulse 120. On the fourth day the temperature was 99·6° F., and the pulse 102°. There was great pain in the course of the musculo-spiral nerve. As there was some tension the stitches were cut. Suppuration ensued, and the wound closed by granulation. On August 20th she went home convalescent.

In this case the definite lobular figure, softening and elasticity of the tumour, and the patient's age, were suggestive of sarcoma, and its restricted mobility suggested a periosteal origin. The freshly cut surface of the tumour, of a translucent pinkish-grey colour, was very succulent; the juice was clear, not creamy as in cancer. Microscopic examination showed the tumour to be a round-celled sarcoma. Before the operation the large size and vascular turgescence of her breasts raised the suspicion of pregnancy, but this was allayed by her statement that she continued regular. The recurrence of sickness on several mornings when it could not be regarded as an effect of the ether led to a direct inquiry and an avowal of pregnancy in the third month.

#### LIVERPOOL NORTHERN HOSPITAL.

EXTENSIVE EPITHELIOMA OF PENIS AND SCROTUM; OPERATION; SATISFACTORY RESULT.

(Under the care of Mr. CHAUNCEY PUZEY.)

In our "Mirror of Hospital Practice" of May 20th last was reported a case, from the clinique of Mr. Pearce Gould, of the Westminster Hospital, of operation for extensive epithelioma of the penis, with some remarks upon the various methods of operation which have been practised in such cases. The following record of a very similar case will be of interest, more especially as the operative proceedings were to a certain extent conducted on the same plan, for the same reasons, and with a like satisfactory result.

T. R—, a quartermaster of an ocean steamer, was admitted into the Liverpool Northern Hospital on Jan. 16th of this year. He was suffering from epithelioma of the penis

and scrotum, which was said to be of about three years' duration; and he was in a most wretched condition. The penis had become converted into a shapeless epitheliomatous mass, in which a portion of the scrotum was also involved. A slight trace of the remains of the glans penis and of the upper wall of the urethra could be distinguished, but practically no penile urethra remained, and a scanty and constant leakage of urine was going on from somewhere in the scrotal portion of the disease, the parts round being sodden with decomposing urine.

At first sight the possibility of complete removal appeared doubtful, but on examination the mass was found slightly movable on the pubis. There was enlargement of some of the inguinal glands on the right side, but there was reason to think that this enlargement was due to irritation, not to infection. A remarkable feature in the case was the condition of the abdomen. Tense, full and hard, it presented an appearance almost resembling that of pregnancy, and this was due to the excessively distended bladder, the fundus of which reached to fully half way between the navel and the ensiform cartilage. It appeared on inquiry that the man had long suffered from organic stricture of the urethra, and that for the last three or four weeks he had been unable to pass any urine voluntarily. The general condition of the patient was very bad; his features were pinched and dusky, his extremities cold and bluish, the pulse quick and feeble, and the respiration hurried and imperfect; the last-named conditions probably being due to the distension of the abdomen interfering with the action of the diaphragm. The propriety of immediate aspiration of the bladder was considered, but it appeared so likely that the bladder must be paralysed and that after-leakage of urine into the pelvic cellular tissue might occur, that we decided to leave the bladder distended one day longer—in addition to the three or four weeks already passed—and to operate next day for the removal of the disease. Every effort meanwhile was made to warm and stimulate the patient, and to bring him up to the mark for operation.

Next day (Jan. 17th), the patient having been etherised, the operation was undertaken. It was conducted slowly, all bleeding vessels, distended veins as well as small arteries, being tied as divided, so as to diminish as much as possible the risk of collapse, the man's general condition being still very unsatisfactory. Two curved incisions were made, extending from a little above the pubis to the perineum, including the whole of the disease and all doubtful-looking portions of skin; the dissection was then carried down, with knife or finger, to the pubic bone, the testicles being held away on either side; the suspensory ligaments of the penis were divided, and then it was evident that a healthy portion of the organ had been reached. The corpus spongiosum was cut through well behind the disease and dissected back a little way, and urine at once commenced to flow freely from the urethra; the corpora cavernosa were transfixed as far back as possible with a stout curved needle, behind which a whipcord ligature was tied temporarily. The penis was then cut through bloodlessly; the dorsal arteries and those of the corpora cavernosa were tied, and the temporary ligature was removed. The wound was then extended down the middle line of the perineum, the corpus spongiosum dissected back for some distance, the urethra, which was found much strictured, was slit up freely, and the cut portions fixed by several stitches to the skin of the perineum. A No. 6 gum catheter was tied in the bladder, and the remainder of the perineal and scrotal wound brought together with stitches, a drainage-tube having been previously laid in and left protruding at each end of the wound. Just enough scrotal integument remained to cover in the testicles, the left lying behind the right. The man having been removed to his bed a long rubber tube was fixed to the catheter so that the bladder might empty itself gradually into a vessel placed under the bed, and no attempt was made to hasten the flow of urine, but rather the reverse, so as to avoid any tendency to syncope from the sudden removal of tension from the abdomen.

Next day the man's condition was better in every way, the respiration freer, the pulse better, the face improved both in colour and expression. The appearance of the wound was altogether satisfactory, and over seven pints of high-coloured urine had drained away since he had been removed to the ward, in addition to a considerable quantity which had escaped during the operation.

There is little more to say concerning the progress of the case, which was uninterruptedly satisfactory. Four days

after the operation, the catheter having slipped out of the bladder, urine began to collect again, so the catheter was replaced and kept in for about a fortnight. There was hardly any suppuration from the wound, the greater part of which healed by primary union, the perineal portion, which filled up by granulation, being fully cicatrised by Feb. 22nd, the day on which the man left the hospital.

Quite recently (May 22nd) this patient presented himself for inspection. He appeared absolutely well in every respect, and said he never felt better in his life; he certainly looked years younger. He said he had no trouble about micturition, could hold his urine for twelve hours if he wished, but generally passed it about every five or six hours. He could do so standing up, but found it more convenient to do so in a squatting position. The pubic and and scrotal cicatrix was hardly perceptible, and there was no trace of the original site of the penis. The scrotum was small, soft, and smooth, the testicles, which are small, lying one in front of the other. The enlargement of the inguinal glands had altogether disappeared. So far the case appears a complete success.

*Note by Mr. PUZEY.*—Some years ago at another hospital I saw the unfortunate result of amputating the penis close to the pubis, and trusting to the stitching of the urethral mucous membrane to the scrotal integument. Extravasation of urine and diffuse cellulitis soon led to a fatal termination. The various methods of making a perineal urethra, with the object of avoiding this accident, were so fully discussed by Mr. Pearce Gould in the report already alluded to, that there is little left to add to the subject. It appeared to me that Professor Humphry's plan of leaving the end of the corpus spongiosum protruding from the perineum was likely to be followed by a constriction as the perineal wound cicatrised. Consequently I had decided to slit up the urethra freely, and stitch it to the edges of the wound; and when in the course of the operation the presence of well-developed organic stricture was manifested, it appeared still more desirable to adopt this plan, the result of which has proved most satisfactory. It was remarkable how soon the bladder regained its power of contraction. We had feared that more or less paralysis of that viscus might have followed its long-continued distension; but its muscular structure was evidently hypertrophied (probably owing to the necessity of overcoming the old stricture of the urethra). When partly filled, the bladder could be felt through the abdominal walls firm and hard, like a solid tumour. This muscular hypertrophy was, no doubt, the reason why the bladder so soon recovered its contractile power. How long the stricture had existed we could not ascertain; sailors seldom trouble themselves about such matters until retention occurs. The subject of this report would appear to have been unusually callous, for with all his extensive disease he had been going to sea until three weeks before his admission, by which time the passage of urine *per vias naturales* had been almost completely obstructed, not by the stricture, but by the epitheliomatous disease.

### KASHMIR MISSION HOSPITAL.

#### A CASE OF COMPOUND FRACTURE OF BOTH ARMS.

(Under the care of Mr. E. DOWNES.)

A LAD, about fourteen years of age, had walked to the hospital with his mother for more than twenty miles after meeting with an accident ten days before. The boy was in great pain. When he was placed under chloroform it was found that the radius and ulna of both arms had been broken one and a half or two inches above the wrists; the upper fragments, the periosteum of which was bared for about an inch, were protruding from the wounds. The wounds on both arms were in a dirty and stinking state; the right arm the worse. There were two wounds, one for each bone, and the right hand was swollen, and pus could be pressed up into the wound from the palm. On the left side the wound was a large jagged one, from which both bones protruded; the vessels on both sides appeared not to be injured. After the wounds had been cleaned the ends of the bones were sawn off, the limbs were put up with bracketed splints, dressing the wounds with lint and carbolic oil.

For days the poor lad lived in the greatest agony. His screams in spite of opiates kept the patients awake at night in the wards. He was moved into a house in the

village; the neighbours, when they found out what a noise the lad made, objected and asked that he might be removed elsewhere. Here he sat and lay, yelling night and day, and in a half delirious state he several times tore his splints with his teeth. Still attempts were made to save him as much pain as possible by giving him opiates.

At last, after about a fortnight, improvement came; the discharge became more healthy, the hands looked more natural, the pain diminished, and his appetite improved. He was then taken back to the hospital where the flies were not quite so abundant as in the village and he was quiet. After about six weeks it was found that there was union in both arms. From time to time several sinuses were slit up in which matter had burrowed, and were carefully dressed. After he had been in the hospital between two and three months he was discharged.

At the time he was discharged there was certainly some deformity; the fingers of the right hand were not of much use, the left hand even was somewhat stiff; the hand could, however, be flexed, and the fingers also; he could even hold a stick with his left hand, though his grasp was not firm. Still he possessed his two hands, such as they were, and his life was saved. He was seen in the following spring begging in the bazaar, and he appeared to have succeeded in his new profession, for he looked fat and well.

*Remarks by Mr. E. DOWNES.*—This case shows well how limbs may at times be saved, even after the worst accidents, if the main vessels are not ruptured, especially in the case of young and healthy subjects. At the same time, if one limb instead of both had been injured, or if the case had been one where to save life was the chief consideration, I do not think I could have ventured to attempt to save limbs when the prospect of success appeared so small and the risk so great. In the summer many of the Kashmiris almost live upon mulberries, which they pick and eat on the trees like monkeys. In June, 1878, the famine had continued for about three months, and the people, being weak, fell from the trees by hundreds. That year I had about fifty cases of simple and compound fractures of different bones, which had been caused in this way, brought to the hospital for treatment; some were very bad cases, and this was the worst of all.

## Reviews and Notices of Books.

*Clinical Lectures on Diseases of the Urinary Organs.* Delivered at University College Hospital by Sir HENRY THOMPSON, Surgeon-Extraordinary to H.M. the King of the Belgians. Sixth Edition. London: J. and A. Churchill. (Student's edition.)—A new edition of these excellent lectures is always welcome; and while there is no part that is not valuable and full of practical instruction, imparted in a very pleasant style, those to whom the general teaching of Sir Henry Thompson is already familiar will naturally turn to the chapter on the results of Lithotomy at a Single Sitting with the most interest. In the preface Sir Henry states that he regards this "modern operation" as "superseeding the old operation, and to a great extent the operation of lithotomy;" and that this is no mere general statement of opinion only, is fully shown by the results of the operation in Sir Henry's own hands during the last three and a half years, during which he has employed this method almost entirely; for the last two years he has employed it without any exception. During that period he has operated on 112 consecutive cases of elderly men—that is, on 112 separate individuals. The mean age of these patients has been over sixty-two and a half years, and no case of mere phosphatic concretion is included in the list. The calculi have been thus composed: of uric acid 64, of oxalates 4, of phosphates 39, mixed 14. The number of deaths has been 3 only. Sir Henry's average mortality with the old operation was seven and a half per cent.; and once he had so few as 6 deaths in 112 consecutive cases. We thus see that in the hands of the accomplished operator and chief exponent of the old operation, the adoption of Dr. Bigelow's suggestion has reduced the mortality by more than half.

Sir Henry Thompson has made a new departure in the form in which this edition is published. Following a course which has been recently pursued in works of general literature, he has issued it at less than a fourth of its former price. It now appears printed in double columns, and in a stiff paper cover. The paper is sufficiently good, and the type excellent; and we hope this experiment may be a success, and that it may find many imitators among the more successful of our medical text-book writers.

*Handbook of Therapeutics.* By SIDNEY RINGER, M.D. London: H. K. Lewis. 1882.—Criticism of a work that has already passed through eight large editions is superfluous. Ringer's *Therapeutics* is a deservedly popular work with the profession, and therefore needs no commendation from us to draw attention to its merits. But even if we had been disposed to criticise, the opportunity is hardly afforded, since there is no very material addition to the present edition, and its increase in bulk is due rather to an alteration in the arrangement of the type than to the importation of fresh material. This is one of the disadvantages rapidly successive editions are attended with—they leave little time for the author to collect and arrange new facts. The two years that have intervened between the two editions, however, have been by no means barren in therapeutical research and progress, and consequently we are somewhat surprised at the slight advance noted in this edition. Perhaps, like a prosperous company declaring an unexpected dividend, the present edition must be regarded as an *ad interim* one, and that in the ensuing issue we shall have the bonus and results of the past two years' work more fully given than in the present volume. Dr. Maxwell of Woolwich has, as usual, prepared the Index to Diseases, and this forms one of the most useful and valuable features of the work.

*On Concussion of the Spine, Nervous Shock, and other Obscure Injuries of the Nervous System in their Clinical and Medico-Legal Aspects.* By JOHN ERICHSEN, F.R.S., Surgeon Extraordinary to the Queen, &c., &c. A new and revised Edition. London: Longmans, Green, and Co. 1882.—This book is so well and widely known that it is only necessary to notice the issue of a new edition. The few alterations made in the text are improvements and valuable additions; yet on the whole there is but little difference between this and the preceding edition. As, however, Mr. Erichsen's experience in these injuries is constantly increasing, each time that he issues a new edition his opinions acquire more value and weight. No attempt is made to conceal the exceeding difficulty of the subject; but all surgeons called upon to give an opinion in cases of the kind here described will find Mr. Erichsen's directions of great assistance.

*Manual for the Physiological Laboratory.* By VINCENT HARRIS, M.D., and D'ARCY POWER, M.A. Second Edition, with forty illustrations. London: Baillière, Tindall, and Cox. 1882.—The number of special works on Practical Histology and Physiology is a proof of the great amount of care and thoroughness with which this subject is now taught in medical schools. This, which is one of the smaller manuals, is already well known, and we need only point out that this second edition has been carefully revised by the authors. It contains many valuable additions; in particular an account of some of the more simple physiological instruments, and of the experiments demonstrating the properties of nerve and muscle. Short accounts of the ophthalmoscope, laryngoscope, and the stethoscope have also been added to the book. In future editions we would suggest that only those methods of preparing tissues for microscopical examination which the authors have themselves found to be really trustworthy should be described. In practical manuals of this class this appears to be the only safe rule.

*Household Chemistry for the Non-chemical.* By ALFRED SHILTON, F.C.S. London: White and Co. 1882.—A practical treatise of this kind supplies a want that has been long experienced. We have often felt that the best first step in chemistry for educational purposes is to make the student acquainted with the nature and composition of familiar bodies in daily use, rather than to commence with abstract principles and experiments with rather intangible materials. Mr. Shilton teaches, and is not merely a popular writer. His first chapter consists of definitions, and certain chemical preliminaries for the student to refer to, and he then plunges at once into his subject. He commences with common washing soda, describes its manufacture and chemical relations with common salt, Glauber's salts, and the manufacture of soap and candles. Air, ozone, combustion, &c., are next described, and then follows an excellent chapter on water, with respect to its purity, hardness, &c. The chemistry of the starches, gums, and sugars is fully described, and there are some interesting remarks regarding the chemistry of fermentation in relation to bread-making, brewing, and wine production. The work concludes with a chapter on food and physiological chemistry. We can heartily recommend the work to teachers as sound, practical, and on the whole accurate.

## New Inventions.

### DR. W. P. MORGAN'S SURGICAL NEEDLE FOR WIRE SUTURES.

THIS is a slight modification of the needle in common use in this country for wire sutures. Instead of a solid "eye," this end of the needle is tubular, the tube opening one-eighth of an inch from the end in a slit one-eighth of an inch long. The wire is passed along the tube and out at the slit. Its

end is then doubled on itself, and the loop so made drawn into the slit. If this be done neatly, the wire does not make any projection on the needle, and the suture can be passed with a minimum of friction and force. At the same time, however, we must add that the needle is not threaded so quickly and easily as the gutter-eyed needle.

### STEVENS' PERMANENT THERMOMETER.

THE chief point in the construction of this instrument consists in the formation of two constrictions, about a quarter of an inch apart, above the bulb. The bore of the instrument in the uppermost constriction is bent at an angle, which allows of the whole column of mercury above this point remaining stationary and serving as the index. A separate detached index is thus dispensed with. The graduation is very distinct, owing to the adoption of a blackened surface along the markings; whilst the column of mercury itself is rather thicker than usual. The instrument is a reliable one. It is made by Messrs. Stevens and Son, of Gower-street.

### ABDOMINAL BELT.

MESSRS. SALT & SON have brought out an abdominal belt with some new features, for which several advantages are claimed. The buckles for fastening the belt are placed well forwards, and the fastening can easily be done by the patient. The straps slide over revolving pulleys, and readily yield to every movement of the body. Adequate provision is made for gradual enlargement of the belt when it has to be worn during pregnancy.

## THE GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

THURSDAY, JUNE 29TH.

DR. ACLAND, PRESIDENT, IN THE CHAIR.

### VISITATION OF EXAMINATIONS.

THE Council went into committee for the purpose of further considering the report on the examinations, 1881-82, of the medical and surgical corporations of the United Kingdom, and the remarks of the said corporations on the report.

Mr. TEALE moved the adoption of the first of the "conclusions" of the visitors, "That it is desirable that every 'primary' or 'first part' examination should include dissections by every candidate." He said he had a strong feeling that of late educational matters in medicine had been drifting into difficulties. Different departments of knowledge had been added or enlarged, and the subjects which the students were expected to bring up for examination had been greatly increased. Those additions had brought them face to face with a necessity for thoroughly reconsidering and revising the whole question as to what should be required of the students, so that the outcome of medical examination and education might be the best attainable—much better than the result at present obtained. Certainly the result was not what it ought to be considering the amount of labour bestowed by students, teachers, and examiners; it was disappointing in consequence of the want of a better distribution of time. The whole subject required careful consideration in reference to the method by which they not only tested but regulated the examinations. One leading object of the visitors had been to make their suggestions bear upon the kind of study brought out in the schools, so that there might be a thoroughly practical development of faculties useful in the profession, doing away as far as possible with that which was evidently growing in all directions—a system of cramming and getting up subjects simply because they were required in the examinations. It was very undesirable that clinical teachers should have to conduct their teaching in reference to the examination; their object should be to teach in the best way they could with a view of making their students practitioners of the highest order. He did not desire that the "conclusions" of the visitors should end in becoming immediately recommendations from the Council. He had no desire to put any strong pressure on the various bodies, but the discussion of the subject by the Council would be of great value; and he had no doubt that it would be extensively read not only by the examiners, but by the teachers. He was aware that the conclusion the adoption of which he had moved did not commend itself to all the bodies. The system proposed was carried out by several important bodies, and he thought it was reasonable to conclude that the practice was a "desirable" one. The principal objection to it had come from the College of Surgeons of England. That body did not indeed deny the desirability of what was proposed; but it had not carried it out on account of the practical difficulties in the way. It was not for the visitors, or perhaps for the Council, to go into the question as to whether a thing of that kind was practicable or not. They had described in their report what was done on a considerable scale by the College of Surgeons of Ireland, and the method there adopted having now been described and put forward authoritatively for the first time, other bodies might perhaps find a way of overcoming the difficulties that had presented themselves. The College of Surgeons of Edinburgh also objected to the proposal, and stated that "few anatomists would consider that such dissections as could be made in half an hour by nervous and anxious candidates would be a fair test of their manual dexterity or anatomical knowledge, whilst it would be an enormous waste of time, which could be better spent in testing their real knowledge." They further stated that the method had been tried by their examiners some years ago, and fell through, not because the system was a bad one of testing knowledge, but because of the mechanical difficulties in the way of carrying it out. The visitors believed that

dissections were the very best way of testing "real knowledge." Examinations should be regarded not only as a test, but as a guide to study, and no one could doubt that if a student had to dissect in his examination, he would work more at dissections than he otherwise would, and would be able to produce infinitely better work than he could accomplish by means of plates and spirit dissections.

Sir WM. GULL said he was aware that there were certain mechanical difficulties in the way. It might interest the Council to know that last year at the London University the highest honours in anatomy were obtained by a woman. He had asked her how she had obtained her anatomical knowledge, and what she had dissected, and she told him that she had dissected the whole body carefully twice. The subject of the examination was the bend in the arm, and she was, of course, well prepared for it. He had no doubt the question had been carefully considered by the University authorities, and Dr. Sharpey, who had guided the examinations, would be admitted to be a high authority.

Dr. LYONS, in supporting Mr. Teale's motion, said that at the Anatomical School of the University of Dublin each student was obliged to dissect, and the examinations had given great satisfaction to those who had taken part in them. With regard to the suggestion that time was wasted by dissections, and that there were better modes of testing real knowledge, he was certainly surprised that such an observation should come from the north of the Tweed. The whole subject of anatomical examination was one deserving the closest consideration. There was no subject on which artificial knowledge had been more assiduously foisted on the profession. He knew of no efficient way of testing the real knowledge of the candidates except that of requiring the students to make anatomical dissections of given parts of the body. No doubt when the views of the Council went abroad they would have considerable effect; and, for himself, he should not be afraid of pushing the matter with as much authority as the Council possessed, and stating not only that the practice recommended was desirable, but necessary.

Dr. PYLE said he believed the University of Durham was the first to institute an anatomical examination. Twenty-five years' dissections in the dissecting room formed part of the examination, and they had done so ever since. He agreed with everything Mr. Teale had said as to the importance of the subject.

Mr. MACNAMARA thought that the recommendation proposed was in too milk-and-water a form, and he should like to see it made much more stringent. The Council had already decided that "In examinations in anatomy candidates should understand that they may be called upon to perform actual dissections, and candidates in surgery should understand that they may be called upon to perform one or more operations on the dead body." With regard to the scarcity of subjects, Professor Redfern had said that such a scarcity would be an advantage, because it would enforce a more thorough use of the subject; the student would have to go deeper in his dissections and not be satisfied with superficial work. He entirely endorsed the statement. What was required for the students was what Dr. Hargrave used to call scalpellary anatomy. Any man of experience in conducting an anatomical examination would at once recognise by the way the student handled the scalpel and forceps whether he had been in the habit of using them or not. He begged to move as an amendment the omission of the words "it is desirable that," so that the motion would read "That every 'primary' or 'first part' examination should include dissections by every candidate." He thought that a very decided opinion on the subject should go forth from the Council.

Mr. SIMON said he felt as strongly as anyone the desirability of dissections forming part of all primary examinations; but he thought the recommendation ought not to go forth in the stringent way proposed by Mr. Macnamara, because there were considerable difficulties in the way of carrying it out, and in some places it might for a time be impracticable. In passing the recommendation as proposed by Mr. Teale, the Council would be giving the bodies a hint that it was their duty to get over the difficulties which they at present encountered.

Mr. MARSHALL said that the College of Surgeons of England was not unanimous in thinking that there was a very great advantage in dissecting, though he believed that a large proportion of the Council thought that dissections were desirable. He could support Mr. Teale's resolution,

but if a stronger resolution, which could not be carried out, were adopted by the Council, he thought the result would be mischievous. If Mr. Macnamara's proposal were adopted the result might be to starve the dissecting rooms and interfere with the general education of the student, diminishing his facilities for dissections and operation on the dead body.

Mr. TURNER said it would be entirely impracticable to carry out the method proposed. He maintained that it was quite possible to conduct a satisfactory anatomical examination without submitting the candidate to the test of actual dissection, and he based his statement on personal experience. He objected to all anatomical examinations where there was no dissected body placed before the student; but he thought it was a matter of indifference whether the dissection was made by the student himself or by somebody else. He admitted that all examinations on dried specimens or specimens preserved in spirit were fallacious in the extreme. He could form as accurate an opinion of what a man had done by seeing how he handled the parts submitted to him as by seeing him actually engaged in the work of dissection. Many of the students in the University of Edinburgh were taught and examined by the professor of anatomy and his associate examiner. Many of the candidates were under personal observation from day to day for years, so that their work was well known, and certificates given at the end of the session. That was a much better test than any half hour's practice on the day of examination. He agreed with the recommendation of the Council that candidates should understand that they might be called upon to make actual dissections, because it was a stimulus to lazy students, and might induce them to work at dissections; but to carry out the system suggested would, he maintained, be impracticable, owing to the scarcity of subjects.

Dr. HUMPHRY said that while he admitted that dissections formed a good feature in anatomical examinations, they were not essential, and in many cases it was impossible to introduce them. He opposed Mr. Macnamara's amendment, and supported the more reasonable resolution of Mr. Teale.

Dr. HAUGHTON said that in the University of Dublin it had been the practice for twenty years for the teachers of anatomy to dissect the bodies carefully up to a certain point the day before the examination, and then call upon the students to complete the dissections. He had consulted some of the distinguished anatomical students upon the subject of dissection at examinations, and their view of it was that it was "only skinning the corpse."

Dr. WATSON agreed that dissections at examinations were desirable, but it should be remembered that students were required to obtain certificates not merely as having been in the dissecting room, but of what they had dissected, and how; and such certificates might be reasonably accepted as an assurance that their instruction had not been perfunctory. He would suggest that the proposed recommendation be qualified by the words "where circumstances permit."

Dr. PETTIGREW supported Dr. Watson's suggestion.

Sir WM. GULL said that certificates were fallacious and worthless. If they could be trusted examinations would be needless. With regard to examinations by the teachers themselves, the Council had already laid down the principle that a teacher should not examine his own students.

Mr. TURNER said that the principle laid down by the Council was that a candidate should not be "wholly" examined by his teacher.

Dr. QUAIN said that great advantage would arise from teaching more medical anatomy and dealing less with dissections.

Mr. Macnamara's amendment was then put and lost.

Dr. WATSON moved, as another amendment, the insertion of the words "where circumstances permit."

This was also put and lost, the numbers being for, eight; against eleven.

The original motion was then put and carried.

#### REGISTRATION OF MIDWIVES.

The deputation on the subject of the draft Bill for the Registration of Midwives attended according to appointment. It consisted of the following gentlemen:—Dr. W. Playfair, Mr. Sibley, Mr. Ernest Hart, Dr. J. H. Aveling, and Dr. Holman.

Mr. ERNEST HART made a statement on behalf of the deputation, and referred to the various efforts made by the Obstetrical Society to promote legislation in reference to it. He also recalled the action taken in the matter by the Local

Government Board, by the Duke of Richmond, and the Medical Council. There were, he said, 10,000 or 11,000 women practising as midwives in England and Wales, assuming that title at their own will and pleasure, and fulfilling their duties without previous education, and without being called upon to furnish any evidence as to their moral character or technical skill. It appeared by the statistics of Dr. Hall Davis that the actual mortality of women attended by skilled midwives—those of the Royal Maternity Charity—was less than the general mortality throughout the country, and that, no doubt, was owing to the fact that so many of the general population were attended by midwives the majority of whom were entirely unskilled, their want of skill more than counterbalancing the advantage derived from the skill of medical practitioners in respect of that part of the population attended by them. The object of the framers of the Bill had been to make it as simple as possible, and it was not desired to throw any expense on the Medical Council. The duty of the Council would be to appoint a board, to approve the regulations formed by that board, and to transmit them to the Privy Council. Local examining boards would be created, but they would not have to meet very often, and their fees would not be large. It was not desired to create any new or superior class of educated women, but to provide for the training and registration of midwives for the poorest classes in cases of natural labour.

Dr. W. PLAYFAIR said that the action taken by the Obstetrical Society was simply tentative and with the view of smoothing away any difficulties that might arise in carrying out the object they had in view.

Dr. J. H. AVELING said that 60 per cent. of the poor women in the manufacturing towns and villages were attended by midwives, and many of them had lost their lives or received injuries from the want of skill of those who attended them. The members of the Matrons' Aid Society, composed of midwives who had passed the Obstetrical Society's examination, were now petitioning Parliament that something should be done to improve their status, and it was urgently necessary that something should be done in the direction indicated.

Dr. HOLMAN, as a medical practitioner, corroborated the assertions made by Dr. Aveling, and added that three-fourths of the midwives in the country were not only ignorant, but generally dissolute women.

Mr. SIBLEY considered that the General Medical Council was the natural guardian of the new movement. The duty of the Council would be to nominate the board and control its action. But very little expense would be involved in the exercise of its powers.

Mr. MACNAMARA inquired if the deputation could state why Ireland was omitted from the Bill?

Mr. HART said it was believed that Ireland was in a better position in respect to midwives than England, and that it had been thought wisest to apply the Bill exclusively to England and Wales.

Mr. TURNER asked for some explanations in regard to payment and fees required by the working of such a measure.

Mr. HART said that the framers of the Bill desired to leave as open as possible the questions relating to modes of payment, which might be better adjusted hereafter; but that it was believed that ample funds would be forthcoming to meet all expenses.

Dr. HUMPHRY asked if the deputation could state what was the general feeling of local practitioners throughout the country in regard to the subject under discussion.

Dr. HOLMAN replied that the opinion throughout the country amongst local practitioners was almost unanimous in respect to the value of the Bill.

Dr. HAUGHTON suggested that there were certain difficulties in the Bill as it affected Wales and Ireland.

The PRESIDENT thanked the deputation, and added that the Council was obliged to the members for submitting their views on this important matter. The Council had received from the Government a copy of the Bill, and had already referred it to a committee of their body. The committee and the Council were glad to have heard the views of the deputation, and would give them their fullest consideration.

#### VISITATION OF EXAMINATIONS.

The Council again went into committee, and resumed the consideration of the report of the Visitors of Examinations.

Mr. TEALE moved, in pursuance of the recommendation in the report, "That having regard to the great and increasing

range of chemical and physiological science, candidates should be informed beforehand of the limits of the examination in these subjects." Everyone, he said, would acknowledge that the area of physiology and chemistry had been greatly extended of late years, and it was therefore desirable that in the examinations some such limitation as the visitors had recommended should be introduced.

Sir WM. GULL seconded the motion.

Dr. SMITH said he considered the motion unnecessary, as the proposed limitation was already included in the recommendations of the Council.

After a brief discussion, Mr. Teale modified his resolution as follows: "That in view of the great and increasing range of chemical and physiological science it is particularly desirable, in regard to these subjects, that examining bodies should comply with Recommendation 40 of the Council, and that the candidates should be apprised beforehand of the examinations in these subjects."

Dr. HAUGHTON asked whether the resolution would apply to the universities as well as to the medical corporations. If it did, he should feel compelled to move that it be restricted to candidates for licences from the medical corporations. The University of Dublin wholly dissented from the recommendation, and would never adopt it. It would degrade their examinations in chemistry and physiology to tell the candidates beforehand of what particular branches they would be examined in. It would be impossible for a high class body like the University of Dublin to adopt such a schoolboy programme.

Dr. SMITH called attention to the following statement of the King and Queen's College of Physicians in Ireland, "The College consider that there are serious objections to define the limits of the examinations in the subjects of chemistry and physiology, and believe that these are sufficiently defined by the scope of the lectures required by the medical authorities. In fact, the College have never had any remonstrance from teachers or candidates regarding the indefinite character of the information demanded on these subjects." Such remonstrance would be almost impossible in consequence of the strictly practical nature of their examinations.

Sir WM. GULL said that the University of London had prescribed certain limits in its curriculum.

Dr. STORRAR thought it desirable that attention should be called to the recommendation of the Council already given with regard to the subject referred to in the motion.

Dr. WATSON moved as an amendment that questions of physiology should be considered apart from that of chemistry.

Dr. PETTIGREW seconded the amendment, which was put and negatived.

The PRESIDENT, in putting the original motion, said he thought it was a matter of great importance that the recommendation of the Council should be enforced, and that special attention should be called to it in the way proposed in the resolution.

The motion was then put and carried.

Dr. HAUGHTON moved, as an addition to the resolution, the words, "For ordinary licences to practise"; but withdrew it on the suggestion that the position of the Universities would be in no way affected.

#### FINANCE.

The Council having resumed,

Dr. QUAIN presented the following report of the Finance Committee:—

"The Finance Committee reports that the income of the General and Branch Councils for the year 1881 (ending January 1st, 1882) has been £6509 7s. 11d., an amount which is £362 11s. 1d. less than the income of the year 1880. The expenditure during the year 1881 has, however, been only £4786 14s., which is less than the expenditure of 1880 by £517 14s. The Committee has, therefore, the satisfaction of reporting to the Council that the excess of income over expenditure for the year 1881 amounts to £1722 13s. 11d., the excess of income for the previous year, 1880, being £1568 1s. Table B annexed to this report indicates the increase and decrease of the several items of expenditure which have taken place during the years 1879, 1880, 1881. From this Table B it will be seen that the chief item of expenditure wherein there has been an increase, during the year 1881, is the visitation of examinations, which amounts to £920 19s. 6d. In the house expenses there has been an increase of £93 5s. 5d., owing mainly to repairs carried out,

and the production of the Medical Register has cost £28 3s. 3d. beyond the amount expended on this item during the previous year. The principal items of diminished expenditure of the year 1881, as compared with 1880, are as follows:—(1) Fees paid to Members of Council, amounting to £493; (2) publication of the Pharmacopoeia, amounting to £483 5s.; (3) Printing, £253 14s. 1d.; (4) law expenses, £83 19s.; and (5) salaries and retiring allowances, £68 4s. 7d. The latter have now ceased. While, therefore, the total increase of expenditure in respect of certain items is £1050 1s. 2d., the total decrease in respect of other items amounts to £1486 13s. 9d., showing, on the whole, a decrease in expenditure of £436 12s. 7d. [From Table C, which shows the average income and expenditure of the General and Branch Councils during the last seven years, it will be seen that the average yearly income, during that period, exceeds the average yearly expenditure by £434.

"Visitation of Examinations.—The Committee deem it desirable to mention the several items, with the view of comparing them with like expenditure in former visitations. The sum of £1279 17s. 10d. (made up of the following items: Visitors' fees, £791 14s.; travelling and hotel expenses, £135 6s.; and printing, stationery, shorthand writers' fees, &c., £352 17s. 10d.) has already been expended in the visitation of the nine medical corporations, and various other sums in respect of expenses incurred have yet to be paid. Comparing the expenditure thus far with that incurred on previous similar occasions, it will be found that in 1873-4 ten visitations were conducted at a total cost of £598 10s., and in 1874-5 thirteen visitations involved a total expenditure of £1174 19s.

"Dental Finance.—Table D shows the receipts and expenditure of the Dental Registration Fund for the year ending January 1st, 1882. In the receipts, £690 16s. 2d., it will be noticed, there is an increase of £74 8s. 11d. over those of last year, while the expenditure, £1148 7s. 3d., has been less by the sum of £680 3s. 4d., leaving the deficiency of income for the year £457 11s. 1d., compared with a deficiency of £1192 3s. 4d. in 1880.

"Investments.—Pursuant to instructions given to them at the meeting of the English Branch Council in 1881, the treasurers have invested £4015 in the purchase of £4000 Consols, in the names of the trustees of the Branch Council, thus making a total now invested under this trust of £29,000 Consols.

"June 23th, 1882." "RICHARD QUAIN, M.D., Chairman.

The report was unanimously adopted, and the Council adjourned.

#### FRIDAY, JUNE 30TH.

Mr. MACNAMARA asked the President (pursuant to notice) whether it was proposed to take into consideration the report of the Royal Commission.

The PRESIDENT said there was no notice of motion on the programme having reference to the subject, and he had received no private notice of the intention of any member to move in the matter.

#### VISITATION OF EXAMINATIONS.

The Council went into committee to resume the consideration of the report of the visitors on examinations.

Mr. TEALE brought up Conclusion No. 3—viz., "That at the final examination candidates should be examined orally or practically on strictly regional anatomy—that is, on the parts of anatomy which illustrate surgery and medical diagnosis, and not purely descriptive anatomy." This, he said, he proposed to bring forward in a somewhat modified form. Like some of the other conclusions, it was in accordance with the previous recommendations of the Council; but some objections had been taken to the form in which it was expressed. The object of the visitors was to call attention to two main points: one that in the final examinations students often seemed to have forgotten very much of their anatomy; and, secondly, that questions were sometimes put in the final examination which hardly came within the range of anatomy, and might fairly be expected at the primary examination. The primary examination in anatomy should be more or less minute, very much apart from its practical bearing, but in the final examination it should have special reference to its practical application. Whatever anatomy was required at the final examination should be thoroughly good and well brought up, and no more should be required than was fairly reasonable. The requirement

was fairly expressed in Recommendation 30, "The candidate shall be examined in medicine, including medical anatomy, and in surgery, including surgical anatomy." The visitors felt that the knowledge of medical and surgical anatomy was not what it ought to be and might be without putting an undue burden upon the students in their final years of study. At the primary examination of the Society of Apothecaries, London, a very good method was employed for testing the students very accurately in their knowledge of the human body and the position of the various organs, and the same thing was carried out from a surgical point of view by the Royal College of Surgeons. The visitors were much struck by the capabilities of the method of examination shown by those two bodies. With a view of bringing the conclusion into harmony with the recommendation of the Council, he would propose it in the following form, "That it is desirable that at the final examination candidates should be examined in medical anatomy and surgical anatomy."

Dr. HAUGHTON objected to the terms "medical" and "surgical" being applied to anatomy. Anatomy was anatomy, and nothing else. They might as well talk of Catholic mathematics and Protestant mathematics.

After some discussion as to the precise phraseology which should be adopted, the Council agreed to the conclusion in the following form, "That at the final examination candidates should be practically examined in anatomy in its relation to practical medicine and practical surgery in accordance with Recommendation 30."

Mr. TEALE proposed the adoption of Conclusion No. 4, "That it is desirable that in every final examination for a surgical diploma a candidate should, as far as practicable, be required to perform operations on the dead subject, in accordance with the intention of Recommendation 44." Such operations, he said, formed a very valuable feature of the examinations. It was thoroughly carried out in Dublin on a moderate number of subjects, and without requiring an extravagant amount of time. Before seeing that examination he should have been inclined to vote against such a proposal, but he was now convinced that it was an extremely valuable method, not only of testing the students, but of directing their work beforehand.

Sir WM. GULL seconded the motion, and, referring to the difficulty of obtaining subjects, said he believed that that very difficulty tended to beget a spirit of reverence in the minds of the students, which was at the bottom of all true science. The student knew that he could not take a human body, like a piece of wood, and do anything he liked with it; and the very scarcity of the subjects was likely to create a feeling of reverence for every living thing.

Mr. MACNAMARA thought that conclusion should be worded much more strongly. Operations at examinations had been in abeyance at several institutions. It was monstrous for a corporation to certify that a man was a surgeon, and capable of performing important operations, without having tested him to ascertain whether he could perform any operation whatever. The fact that a student knew that he would certainly be called upon to perform certain operations would be of the greatest value in surgical education. If the bodies that had hitherto ignored the recommendation of the Council on that subject would try the experiment, he believed they would find it successful; but if they found that it "starved" the dissecting room, as had been suggested, they could of course abandon it.

Mr. MARSHALL agreed that the recommendation should be carried out wherever it was practicable, but he did not believe in its absolute necessity, and in many cases it would be quite impossible to carry it out. It was impossible to teach the students to perform all operations. In the College of Surgeons the operative classes were well carried out; but even there it was impossible to enable any individual student to perform more than ten operations, and there was a drag upon the anatomical supply to meet even that slender requirement. It was better to teach well and examine imperfectly than to teach imperfectly and examine highly. Their forefathers were not so completely examined, but there were no better surgeons than they proved themselves to be. His own master was not a highly examined man, but he would rather allow him to take off his arm than any person he had ever known.

Dr. CHAMBERS said that the duty of an examiner was to ascertain whether a man had gone through a course of operative surgery, and that could easily be ascertained by seeing how he performed one or two operations.

Mr. TURNER agreed with everything that had fallen from Mr. Marshall.

Dr. HAUGHTON said he should prefer the omission of the words "as far as practicable"; but perhaps they were required by the necessities of the case. He thought that every effort ought to be made to render the method compulsory.

The motion was then put and agreed to.

Mr. TEALE brought forward Conclusion No. 5 in the following modified form, "That it is desirable that the examination in operative surgery should for the most part be directed to emergency operations, such as amputation, deligation of arteries, catheterism, tracheotomy." The object, he said, was not to push the extension of examinations too far. Common sense should of course be brought to bear upon the subject, and it evidently required that a man who went out as a general practitioner should be able to give some sort of guarantee that he knew how to amputate a limb and perform such other operations as he might be called upon to do at any moment. It was not desirable, however, to press things that were not absolutely essential.

Mr. MARSHALL thought it would not be wise to tie the hands of the examiners by limiting the operations which the students were required to perform.

Dr. HAUGHTON said if the particular operations were specified, teachers would teach nothing else.

Mr. TURNER thought a great deal ought to be left to the discretion of the examiners.

Dr. HUMPHRY thought that no recommendation should be passed on the subject. "Emergency operations" could not be defined. The result of such a recommendation would be to restrict the range of teaching without benefiting the examinations.

After some further discussion, Mr. TEALE said that he was satisfied with the discussion that had taken place, and he would therefore withdraw his motion.

The next "conclusion" of the visitors was then read, "That the application of bandages and splints should be required in every surgical and clinical examination."

Mr. TEALE, in moving its adoption, said that the students, in preparing themselves for this part of the examination, would not be wasting time, but would be qualifying themselves for their professional labours without overtaxing their brains.

Sir WM. GULL seconded the motion, but suggested the omission of the words "and clinical."

Dr. HALDANE, in supporting the motion, called attention to the remarks of the visitors in reference to the clinical examinations at the College of Physicians and Surgeons of Edinburgh: "Another weak point was that there was no systematic provision of padded splints for the candidates to select from, as was the case at the Glasgow hospitals; but each candidate had to apply to the ward nurse for the materials he needed, and make the best of what the nurse chose to supply. The Glasgow plan not only economises time, but appears to be a more adequate test of the efficiency of the candidate." The surgical examiners entirely disapproved of these observations of the visitors, believing that it was far better to test the candidates' knowledge by making them select the splints themselves. Each candidate was in the same position as a surgeon in his infirmary; he did not take what the nurse might choose to supply, but asked her for what he wanted. If it were understood that the splints alluded to were not to be padded, but left to the judgment of the candidate, he should agree with the resolution.

The motion was then put and carried.

With reference to Conclusion No. 7, "That the examination of normal and morbid urine should be an essential part of every clinical examination in medicine,"

Sir WM. GULL questioned the propriety of the examiners dealing with one excretion only, and added that he had himself gained more information by the examination of stools than of urine.

Dr. HAUGHTON said that if the conclusion were adopted students would never study anything but urine all their lives.

Mr. TEALE said he would not press the motion, and it was accordingly withdrawn. He then proposed Conclusion No. 8, "That the practical examinations in chemistry should, when feasible, be conducted in a laboratory." He said if the examination in practical chemistry were to be anything like a  *viva voce*  examination of the candidate in a quarter of an hour.

Dr. HAUGHTON suggested the omission of the words "when feasible," and said that it ought always to be feasible. He could not conceive of there being any practical difficulty in the way.

Mr. TURNER asked what was meant by a laboratory.

Mr. TEALE said that the visitors did not mean a permanent laboratory, but would be satisfied with a temporary laboratory fitted up for the purpose of the examination. The object was to have the examination conducted distinctly from the *visd voce* part. The candidate should be able to go to a separate table with appropriate solutions and tests which he should be required to recognise.

Dr. HAUGHTON said that a few solutions on a table would not be sufficient. The candidate should be required to go into a laboratory and do certain things that could only be done there. If the examination were not carried out in that way, he should prefer to have it entirely conducted by written papers.

Mr. TURNER said he presumed that examiners would be satisfied with qualitative analysis and would not require quantitative analysis; a judicious selection of tests, he thought, would be generally sufficient.

Dr. PITMAN said that the examination in practical chemistry of the College of Physicians was conducted in a laboratory especially fitted up for the purpose; and he should be glad if the visitors would inspect it and see how carefully the College had provided for the examination.

Mr. MACNAMARA supported the motion.

Dr. STORRER described the method adopted by the University of London examinations, which, he said, were conducted in a large room fitted up as a laboratory with a series of compartments or boxes for the candidates, who were required to give written answers to the questions as the results of experiments that they were obliged to undertake.

The motion was put and agreed to.

Mr. TEALE then read Conclusion No. 9: "That a practical knowledge of the histology of tissues and chief organs should be required of all candidates for medical or surgical diplomas," which he said he felt inclined to withdraw, as being too much a matter of detail.

Mr. TURNER said that the Council had already issued a recommendation on the subject to the effect that observations with the microscope should form a part of the examinations of the candidates for licences.

Mr. SIMON said that if the recommendation had not been properly carried out (as appeared from the remarks of the visitors), some resolution ought to be passed directing attention to the subject.

Mr. TEALE said that the visitors were of opinion that in the examinations of some of the bodies the recommendations of the Council had not been sufficiently attended to. He then proposed, "That it is desirable that the recognition of microscopical specimens, normal and morbid, should form a part of the examinations for medical and surgical diplomas," which was seconded by Dr. PETTIGREW, and, after a short discussion, was agreed to.

Mr. TEALE then moved, "That in oral examinations, where the time allotted is strictly limited, for instance, to ten minutes or a quarter of an hour, there is a serious risk that candidates of an average ability who have been conscientiously taught and fairly prepared in their work may be rejected owing to misunderstanding or nervousness, and this is a hazard which, reacting as it does injuriously upon study and teaching, ought to be, if possible, avoided by allowing a margin of additional time for satisfying the examiners in all such cases. The actual practice of certain boards, and especially of the Colleges of Physicians, shows that this suggestion is not impracticable, although it may be more or less difficult to carry out where the numbers are very large. The visitors think that no mere difficulty of mechanism should be allowed to interfere with its being adopted as a measure of justice to candidates." The motion, he said, raised a point to which the attention of the visitors was directed—namely, the cause of the numerous rejections. In all the bodies a very large proportion of the candidates, varying from one-third to a half, was rejected. With regard to the College of Surgeons of England, especially, he could not but think that the very perfection of its splendid mechanism not unfrequently led to unnecessary rejections. They all knew that the College of Surgeons was generally reputed to reject candidates who in the opinion of their teachers and fellow-students were thoroughly good, and there was, he thought, sufficient testimony to show that

that happened more frequently than it ought to do. He desired to be understood as speaking only of the primary examination. As an illustration of what he meant he might mention that an anatomical teacher and an examiner in anatomy in another body, who had sent up a dozen candidates for the April examination, told him that he knew that several of the candidates would be rejected, but he could not say which. It was an unfortunate thing if, in a good examination, men who were industrious and well prepared could not have a reasonable certainty of passing, and he could not help thinking that the uncertainty that existed would lead to some amount of cramming, and the spending of a good deal of time in over-preparation in order to make the candidates secure. In order to obtain absolute fairness and impartiality the examination at the College of Surgeons was divided into four stages, each conducted by a different examiner, so that there was no possibility of any general view being taken of what the students had done. Of course, the reasons for continuing that method might be insuperable, but he desired to point out the impressions made upon the visitors that the system of marking adopted led to a certain amount of uncertainty. If, for example, a candidate obtained three marks for his paper on physiology, and then came up for the *visd voce* examination, and the examiners hesitated whether they should give four or five marks, the total aggregate number being eight, their decision would decide the question of his passing; they would not be guided, in arriving at it, by what the candidate had done before, but simply by the part of the examination which they had themselves conducted. If the examiners saw the paper work in addition to hearing the *visd voce* examination, they would be able to give a fairer judgment on the whole matter. Again, so much of the examination was conducted by the rigid quarter of an hour rule that many candidates were unable to do themselves justice. If a candidate were questioned upon a point with which he was not thoroughly familiar, and spent a little time upon it, his chance was almost gone. The examinations appeared to be conducted with the object of seeking for ignorance instead of for knowledge. In so wide a subject it was impossible that every candidate should be thoroughly up in every part of it, and any candidate, therefore, might be questioned upon a point upon which he was weak. Some of the examiners, the visitors observed, acted with great judgment in occasionally helping the candidates where they hesitated, and so economised time. He did not suggest that the Council should ask the College of Surgeons to make any alterations, but it was well perhaps that the Council and the College should know what was the feeling of impartial visitors on the subject, in order that they might take it into serious consideration. At the examinations of the College of Physicians more time was given in the *visd voce* part.

Dr. BANKS seconded the motion.

Mr. MARSHALL said he should be able to show that the "general impression" alluded to by Mr. Teale was incorrect. The visitors had laboured under a great disadvantage from the fact that their visitations were upon a come-and-go principle; and he believed if they had witnessed a year's work of the College of Surgeons, and examined the whole of the statistical results, they would have arrived at a different conclusion. He did not deny that there might be individual cases of hardship; and those cases would, of course, be more numerous where there was a very large number of candidates than in the examinations of smaller bodies. Comparing the rejections at the primary or scientific examinations of the different bodies, he found that the percentage of rejections at the College of Surgeons was lowest of all, being 29½ per cent., which showed distinctly and conclusively that the examination was not so severe as had been suggested. He did not complain that the visitors had brought the subject forward, because it was useful that the examiners of every institution should be occasionally reminded of the peculiarities of their examinations. The visitation was an admirable one, and had done a great deal of good; but in looking at the subject, the Council should view it as broadly as possible, and not always take a candidate's or a teacher's view of the cause of rejection, or even a visitor's view. The examiner was superior to the visitor, knowing the kind of men who presented themselves, and having a duty to fulfil to the College, by whom he was appointed. He considered that there was something a little out of the way in the Council calling the bodies to account for their rejections.

The further consideration of the motion was adjourned.

The case of David Beatson Murdoch was considered in private, and he was summoned to attend the Council on Tuesday.

#### SATURDAY, JULY 1ST.

The Council, in Committee, resumed the consideration of Conclusion No. 10 of the Visitors' Report with reference to the time allowed for examinations.

The PRESIDENT reminded Mr. Teale that the conclusion which he had moved was not strictly in the form of a resolution, and therefore required modification before being submitted to the Council.

Dr. HAUGHTON dissented *in toto* from the recommendation of the visitors, who, he said, had lost themselves in a labyrinth of words. As a practical examiner he could not accept the view that candidates of average ability who had been conscientiously and fairly prepared were likely to fail from "misunderstanding or nervousness." For those two words he would substitute "ignorance or stupidity," which had probably a great deal more to do with the rejections. Mr. Marshall's comparison of percentages completely destroyed the force of the visitors' recommendation. The proportion of the College of Surgeons, 29½ per cent., was the lowest in the table except that of Trinity College Dublin, which was 28 per cent. Some examining bodies boasted of their high proportion of rejections; but the fact was that figures of that kind formed no test of the severity or purity of the examinations; they only showed (assuming that they were pure) the relation of the preparedness of the candidates to the examinations. In some of the best examinations of the University of Dublin, outside the medical school, the proportion of rejections was not 5 per cent. The students knew what the standard was, and it would be a disgrace to their teachers if they were plucked. Mr. Marshall's figures showed that at the College of Surgeons a smaller proportion of candidates was rejected than at other corporations; and he had no doubt that the examination was conducted in such a way as to give a fairly prepared candidate every facility for passing. He could not agree with the visitors in regard to the fifteen minutes' question. He had often found in examining a candidate *vis à voce* that he could make up his mind to pass him in five minutes, while another would require ten. As far as he could judge, a quarter of an hour was quite long enough for testing *vis à voce* in anatomy and physiology. In the examinations at the University of Dublin the whole court of examiners came together to discuss the cases, and no power of veto rested with any of them. He did not think it was well to put such a power in the hands of any examiner. Such a system would be more likely to lead to the rejection of well prepared candidates than any amount of nervousness; and if rejections of that sort were numerous it was evident that something ought to be altered in the system adopted for examination.

Mr. TEALE said he proposed to bring forward his resolution in the following form, "That in oral examinations where the time allowed is strictly limited, for instance, to ten minutes or a quarter of an hour, there is a serious risk that candidates of average ability who have been conscientiously taught and fairly prepared in their work may be rejected for a misunderstanding or nervousness, and this ought, if possible, to be avoided by allowing a margin of additional time for satisfying the examiners in all doubtful cases."

Dr. SCOTT ORR said that Mr. Marshall's observations were worthy of the serious consideration of the Council; but he thought that some latitude should be allowed with regard to the time during which the candidates were examined. Five or ten minutes might be sufficient to test a good candidate or a very bad one; it was the middle men who were the most difficult to test, and many of them might require more than the prescribed time.

Dr. BANKS, in supporting the resolution, said he disclaimed any idea of throwing blame upon anyone. At the final examination of the University of Dublin candidates had frequently complained to him that the time was too short. He did not agree with Dr. Haughton that the slow men were necessarily stupid. There were many who were not quite so bright and ready as the others, but who were by no means stupid, and who, if sufficient time were allowed, would be able to pass the examination.

Dr. LYONS said that some candidates could be tested in a very few minutes, but others, whose comprehension was slower, required a longer time. He thought that an undue

amount of attention was sometimes paid to examinations. He agreed with the late Dr. Stokes, who said he would rather secure a perfect system of education than a perfect system of examination. Slow students often turned out better men than those who were more brilliant. What was wanted was to test the knowledge of average men. The system of examination had its faults as well as its merits, and no doubt many able and useful men were shut out of the public service only by the system of competitive examination, while a number of weedy horses, because they were able to put on a spurt for a moment, were admitted.

Mr. MACNAMARA said it should be borne in mind that the fifteen minutes' *vis à voce* examination was supplemental to the written examination. If a candidate did not know anything about the subject in which he was examined a very few minutes would suffice to ascertain the fact, and a prolonged examination under such circumstances would not be attended with any advantage. It was necessary where there was a large number of candidates that the times should be so arranged as that the students might come on in their proper order. He never heard rejected candidates complain that they had not time enough; probably they had too much, and the longer they were under examination the more reason they had to regret it. He thought it undesirable that the Council should descend to such matters of detail, and that some latitude should be allowed to the corporation in the working of their various systems.

Mr. TURNER said that when he was an examiner at the London University he learned the great value of some latitude being allowed as regards time. At Edinburgh at first there was no such latitude, but at present there was, and he had sometimes occupied as much as half an hour in the examination of a candidate, while on the other hand he had occasionally disposed of one in ten minutes. When the time was limited he was afraid that justice was not always done in the case of sensitive and shy men.

Dr. HUMPHRY said he did not understand what was meant by the expression that some examiners examined as if their object was to find out ignorance, and others as if to find out knowledge. It appeared to him that he could not do the one without doing the other. Examination and education were reciprocal, and if the Council perfected the former it would perfect the latter. At the College of Surgeons, although a veto might be given at a particular table, it must always be by two examiners; and it almost always appeared that a candidate vetoed at one table had not gained sufficient marks at the other tables to entitle him to pass even if he had not been vetoed. If the marks were so near that he would almost have passed, an opportunity was given to the examiners to reconsider their decision. He very seldom found that any of his pupils who he thought ought to pass were rejected by the College of Surgeons. In his opinion the definiteness of period, while having certain disadvantages, had also certain advantages. It caused the examiner to commence at once, and avoided those few minutes when the candidate would otherwise be nervously wondering what he was going to be asked. But there were cases in which a man answered scarcely well enough and the examiners felt in some doubt. Then it was desirable that a larger amount of time should be given. He was therefore willing to assent to the view that some little latitude should be given as to time.

Dr. PETTIGREW supported the motion, because he considered that everything possible should be done to protect the students. Examinations did very little for a man, the teaching and training doing everything. To many men rejection was equal to condemnation, and if a little latitude were allowed many a good man might be saved the mortification of rejection.

Dr. HALDANE said he regarded this question as one of detail, into which the Council should not enter. It was a subject for the bodies and the examiners to decide upon. As stated by Mr. Turner, the University of Edinburgh had changed its system, and a similar change would take place wherever it was found necessary, and therefore the Council need not lay down a formal resolution on the subject.

Dr. PITMAN said that formerly the practice in the College of Physicians was to limit the time to a quarter of an hour, but it was found to be so unjust to the candidate in some cases, that power was given to the examiners to deal as they pleased with the matter of time.

Dr. QUAIN said one point appeared to have been overlooked in the discussion—namely, the sacred duty of the

examiner to the candidate. What could be more unjust to a man than to reject him, when, perhaps, five minutes more would get him over his nervousness? Some examiners, too, committed the fault of trying to display their own knowledge.

Mr. MARSHALL said that the total rejections at the College of Surgeons amounted to 29.75 per cent., and out of 111 rejections only 11 were actually vetoed. On the whole, he was in favour of a fixed time for the examinations; but there might be a qualification permitting an extension in doubtful cases. The practice of the College of Surgeons was in accordance with that principle, and the reason why it did not appear that many men had the advantage of it was that the system of veto was much more gentle in its operation than might be supposed. The large majority of the rejections were of those who failed to get the requisite number of marks, and did not arise from the individual action of one table.

Mr. SIMON did not regard the question as one of mere detail. It was rather whether certain examinations were as certain in their results as they might be. It was of supreme importance that all candidates should be able to expect the greatest attainable certainty of result in all the examinations; and he agreed with the visitors that with a hard-and-fast line as to time such certainty could not be absolutely reckoned on.

Dr. CHAMBERS said at the College of Surgeons, Ireland, the *viva voce* examination was supplementary to the paper work; but at the College of Surgeons, England, the *viva voce* examination was quite independent of the written examination. In the latter case, therefore, more time might be required.

Sir WM. GULL said he was quite sure that in consequence of nervousness a good many men were rejected who ought to pass. The duty of the Council was to protect the students as far as possible, and he thought they might come down upon the examiners a little and see that they did their work thoroughly well.

Dr. PETTIGREW regarded examinations as a necessary evil, and thought the Council would make a great mistake if they attached too much importance to them. He knew one case where a student was rejected, not only at a first, but at a second, examination, but he was now a professor of European reputation.

Dr. BANKS said there were some examiners who when they found a candidate weak upon a subject pertinaciously stuck to that subject, instead of taking him over a large range and endeavouring to find out what he really knew. Under such an examination good men might frequently be rejected. The object should be to elicit what was known, and therefore he strongly advocated the elasticity of examination.

Dr. STORRAR said that some thirty-five years ago Dr. Sharpey, when examining a candidate at the London University, asked, "Can you tell me anything about the circulation of the blood?" The answer was, "The blood goes out of the heart, down one leg, Sir, and up the other." Dr. Sharpey was equal to the occasion, and asked, "And how does it get across?" That was an extravagant illustration of the state of mind that some students got into, and their answers were then no indication of their intellectual powers.

Dr. HAUGHTON said that the report of the visitors left an unpleasant impression upon his mind that there was a charge against the colleges that owing to the absence of some such rule as that referred to in the motion substantial injustice had been done to some candidates. To his mind such a charge was utterly unfounded.

Mr. SIMON said that the question under consideration was not the historical one whether injustice had been done, but whether the tendency of the system was to do it.

Sir WM. GULL said there was an impression abroad in large medical schools that there was an uncertainty in the examination, that a man might be well-informed and yet get rejected.

Mr. MARSHALL said if the resolution were to be associated with such an impression in regard to the examinations of the College of Surgeons, that body would undoubtedly send some answer to the Council. Dr. Chambers had referred to the fact that at the College of Surgeons, Ireland, the written papers were laid before the oral examiners; but what was the use or justice in testing a man's knowledge of having the answers given three days before placed before the examiners in order that they might enable the candidate to correct some errors in the paper? By that time he

had discovered what blunders he had made, and had prepared correct answers. It was much better that the examiners should act independently and give independent reports.

Dr. LYONS suggested that a little verbal alteration in the motion would be advisable, so that it should read, "That in oral examinations, notwithstanding any general rule which limits examinations to ten minutes or a quarter of an hour," &c.

Mr. TEALE, in reply, reminded the Committee that it was an instruction to the visitors to inquire into the causes of the numerous rejections, and that was the ground on which this subject was brought forward. If the recommendation had needed any justification the discussion had afforded it. Mr. Marshall had supported his view by statistics; but the statistics for the last five years showed that the rejections in the primary examination at the College of Surgeons (England) were 33 per cent.; at Edinburgh, for the double qualification, 36 per cent.; and at the College of Surgeons (Ireland), 40 per cent. At the first of these there was a practical sifting before the examination, so that the candidates came up better prepared. He hoped that none of the resolutions on this subject would be taken as reflecting upon anybody. In framing them he was entirely free from any such feeling.

The PRESIDENT said that no one who looked at the whole tenor of the report could doubt for one moment that the suggestions of the visitors were expressions of convictions forced upon their minds after long and laborious investigation of the examinations over the whole country. Anyone who had been in the Council for many years must feel that instead of recriminations between different bodies as to the numbers of persons passed who ought not to have passed, the discussion had been one of the quietest and most serious that had ever occupied the time of the Council. Their object had been to ascertain whether it was or was not true that some examinations were uncertain, and whether that uncertainty implied the occasional rejection of really good men. The total result of the whole discussion was the bringing of the whole force of the representatives of all the examining bodies to see in what way the examinations could be made more perfect in all their parts. He was only surprised that there should be any doubt at all that under the severe intellectual pressure brought to bear upon the candidates many excellent persons failed, not from want of knowledge, but from want of power to endure the strain of the examination.

The resolution was carried with five dissentients.

On the motion of Dr. PITMAN, seconded by Mr. TEALE, the Council resumed.

Mr. MACNAMARA called attention to the case of Mr. Hartley Dixon, concerning whom a letter had been received from the South Australian Branch of the British Medical Association, complaining of certain proceedings on the part of the Apothecaries' Hall of Ireland. He said that this letter was referred to the Executive Committee, who, after ascertaining the facts of the case, forwarded the answer of the Apothecaries' Company to the South Australian Branch of the British Medical Association. He could not understand why the committee had taken such a step, instead of bringing the subject before the Council, and having the whole matter settled. He was satisfied that the governor of the Apothecaries' Hall was ready to prove to the Council that the Company had acted strictly within its legal rights. He therefore thought the subject should now be taken into consideration.

Mr. COLLINS asked if the question would be reopened in case any reply should be received from the South Australian Branch of the British Medical Association.

The PRESIDENT said it was not quite clear what further light could be thrown upon the subject until the reply was received.

On the motion of Mr. MACNAMARA, seconded by Dr. HAUGHTON, the further consideration of this matter was adjourned till Monday.

#### REPORT OF PHARMACOPOEIA COMMITTEE.

Dr. PITMAN moved that the following report of the Pharmacopoeia Committee be received, entered on the minutes, and adopted:—

"The Committee have to state that after due inquiry they have not obtained sufficient information to enable them to report in accordance with the terms of the Council's resolution, 'That it be an instruction to the Pharmacopoeia Committee to report to the Council year by year as to

addenda.' The Committee report further that the present stock of the last edition of the Pharmacopœia amounts to 2550 copies, and that the average annual sale is about 1000 copies; thus a fair estimate may be obtained as to the period at which it will become necessary to supply a new edition. With a view of taking steps towards the publication hereafter of another edition of the Pharmacopœia, the Committee make the following recommendations:—(a) That the Pharmacopœia Committee be a standing committee until the issue of the work; (b) that the Committee be authorised to appoint from amongst its own members a sub-committee, to assign to it such duties as it may think fit, and to take such other steps as may be necessary for fulfilling the duties assigned to it; (c) that a sum not exceeding £100 per annum be placed at the disposal of the Committee.

"June 30th, 1882." "RICHARD QUAIN, M.D., Chairman.

Dr. A. SMITH seconded the motion.

Dr. STORRAR wished for more detailed information as to what the committee were about to do before the Council gave them power to expend £100 a year.

Dr. QUAIN said it was proposed that the sub-committee should take steps to appoint editors who would draw up a report to be submitted to the Council as to what should be done with regard to the Pharmacopœia. No steps could be taken towards issuing the work until the reports came before the Council.

Mr. SIMON expressed a hope that at least one of the editors would be a person well acquainted with pharmacology abroad.

The resolution was agreed to.

The standing orders having been suspended on the motion of Dr. Pitman, seconded by Mr. Turner,

Dr. CHAMBERS moved "That a committee be appointed to consider the abuses which arise from the employment of unqualified assistants by registered practitioners, and to report to the Council whether any means can be adopted for checking these abuses without diminishing the conveniences of the present practice." His reason for bringing forward this motion, he said, was not so much the complaints of the public as the serious injury done both to the good fame and to the pockets of the profession by the abuses complained of. In the north of England the miners preferred bone-setters to properly qualified practitioners, who were often sent for only when the patient was dying.

Mr. BRADFORD seconded the motion.

Sir WM. GULL said there were bone-setters in London who were much more believed in by some people than experienced Fellows of the College of Surgeons; but the Council had no power to deal with that subject. Unless a man's name was on the Register they had nothing to do with him.

Mr. SIMON thought the Council might explain to the profession what they considered an abuse of the employment of unqualified persons.

Dr. HAUGHTON said that His Grace the Archbishop of Dublin employed a bone-setter only six months ago.

Dr. A. SMITH recommended the omission of the words "without diminishing the conveniences of the present practice."

This was agreed to, and the motion was carried unanimously.

The Council then adjourned.

#### MONDAY, JULY 3RD.

The Council resolved itself into committee to resume consideration of the conclusions arrived at by the visitors of examinations.

Mr. TEALE moved the 11th conclusion, "That with a view to the economy of the time of the examiners it is desirable that when a candidate has obtained rejecting marks in the written portions of an examination he should not be required to proceed to the oral." He said he had hesitated as to whether he should bring forward this motion or not, but two members of the Council had expressed a wish that he should do so. The visitors felt that after they had recommended certain points which would seem to impose additional labour on examiners in order to make the examinations more satisfactory, some consideration should be given as to how this could be done without calling upon the examiners to spend more time on the examinations than they did at present. If there was one thing that had struck the visitors more than another it was the amount of voluntary work that was done in the examinations. It was quite clear to them

that unless a large number of leading members and teachers of the profession were content to devote their time to the work of the examination of their bodies from a feeling of *esprit de corps* the bodies could not command the high standard of examiners that they did at present. He was extremely anxious that the examinations should be in the hands of the profession and the bodies themselves rather than relegated to anything like a State appointment, because a State-appointed body would be pledged to one of two courses, either to go to infinitely greater expense to command the services of such men as the bodies now command, or to throw the examinations into the hands of persons very much less experienced. In this point of view economy must be searched for in the method of examinations; therefore it was thought that students who were hopelessly condemned by the marks they had obtained in their paper work should not be dragged through the oral examination. He was quite aware that there were very forcible arguments against this, but the point to be considered was which course was open to the least objection. Akin to this was another suggestion, which, from its novelty, had not been well received, but he was sure that in due time it would receive consideration—namely, that the paper work should be carried on in England at the seats of teaching, thereby candidates might be saved coming up to the centre for examination.

Mr. MACNAMARA seconded the motion. He said that the visitors stated that the difficulty "had been solved by the Irish College of Surgeons in a remarkable manner." Such evidence having been brought forward it would have been a very unsatisfactory thing if the matter had been regarded simply as one of detail, and had not been brought under the consideration of the Council. It was perfectly clear that when a candidate entirely failed in the written paper and then went to the oral examination, a certain amount of useless work was thrown on the examiners. If the written examination was of importance, and a man showed he was wholly unable to pass it, to permit him to go on implied a certain amount of doubt as to the value of the written examination. It had been stated that to adopt the course suggested by the visitors would lead to an insufficient paper examination, but such was not the experience in the College of Surgeons, Ireland. It struck him that it would be advantageous for England if a great portion of the examination was conducted at the local centres, and the papers sent up to the examiners of the College, so that they might frame a list of those who had passed and those who had not passed. Then the candidates would know whether it was of any use their coming up to London for the oral examination. In the College of Surgeons, Ireland, if a man failed at one examination, he did not come up to the next. He was perfectly satisfied that the motion would not be carried, and he had very little doubt that ultimately the Council would see the propriety of endorsing this most important conclusion.

Dr. WATSON said he had been exceedingly anxious that this matter should not be allowed to pass without some remark with reference to a subject which might be said to be germane to the recommendation contained in it—namely, the question of the unfortunate rejected candidates. In most cases, when a candidate was rejected, he had to come up again for examination in the whole of the subjects which constituted the examination, and that appeared to be a great hardship. This condition of things was particularly unsatisfactory to the candidates with reference to the second or practical part of the examination, because the great mass of non-qualified assistants who should, if possible, be got rid of, came from the men who had been rejected in their second examination in the practical part of medicine, surgery, and midwifery. He urged the committee to consider whether some instructions could not be added to the conclusion in the direction of recommending to the examining bodies the propriety of re-examining a rejected candidate only in those subjects which he had previously failed to pass in. The mental condition of some men was such that they were unable to take up more than a single subject at a time to learn it thoroughly. He thought it would be advantageous if some such instructions as the following were added: "And that where a candidate has been referred in his written and oral examination only because he has not obtained pass marks in one or more, but not in all, the subjects, when he again comes up to examination he should not be examined in those subjects in which he had obtained satisfactory marks; and that any candidate who has once been referred may take any of the subjects in detail, and

should not be obliged to present himself for all the subjects included in that examination."

Mr. SIMON said he must at once enter a *caveat* as to some of the principles affirmed in Dr. Watson's speech. They would get into extreme danger with regard to the whole object of education if they admitted the principle of passing by instalments. The meaning of the licence was that at the moment of obtaining it a man was in possession of certain knowledge, not that at some antecedent period of his life he knew such or such a thing. If they were content with successive crams and little bits of passes it would be impossible to say what the worth of the guarantee was. As regards Mr. Teale's proposal, if that were the Council of the Royal College of Surgeons, and he had the honour of being a member of it, he should certainly vote for the resolution; but whether it was worth while for this Council to press it against the feeling of the representative of the College was a different question, and the subject was not one of such importance as to entitle them to take that course. The economy of time would be very small.

Dr. HUMPHREY thought it would not be wise for the Council to pass such a resolution, requiring or recommending a certain method of examination to the several bodies. The bodies should be left to conduct their examinations in such a manner as they themselves found best. He considered that the practice of the Royal College of Surgeons of Ireland to re-examine a rejected candidate from the point at which he had previously stopped was very objectionable. If the several bodies proceeded on that plan it would soon be necessary for the Council to visit the examinations in a different sort of spirit from that in which they had proceeded lately. It would also tend to make the examiners more liberal in their marks, if they felt that a failure in one branch of the examination shut a candidate out from the opportunity of passing in the other branches. A candidate who was rejected had to bear whatever discredit appertained to the plucking, and he ought to be allowed the advantage of going through the whole examination again. He himself had been surprised at the improvement which took place in candidates during the interval between rejection and re-examination, and he attributed it very much to the experience which the men had had of the examination in the first period. It should also be remembered that examinations were one means of lengthening the period of education to the required point. A large number of the more intelligent and diligent students could prepare their subjects in four years, but others could not do so, and were therefore referred back for further study. He felt very strongly that such candidates should have the full benefit of a second examination.

Dr. QUAIN said that the influence which the Council had had on education and examinations had not been obtained by interfering too minutely with the examining bodies, but by laying down general principles. If they went too minutely into these subjects the different bodies would all say, as the College of Physicians in London had said, "We have done it, and we will continue to do it."

Mr. MARSHALL said he should certainly vote against the resolution. If the plan suggested were carried out, the greatest economy of time that it could effect would be no more than one hour per day, and the examiners did not wish for that economy. He regarded the examination as a whole, although for practical purposes it was divided into written, oral, practical, or clinical; and it was decidedly better that a candidate should pass through the whole examination before the result was made known. The education afforded to a man by going through the examination was of very great importance, for it taught him how to prepare himself for the future. If they rejected him on the written examination it deprived him of obtaining any experience from the oral examination. To permit a man to pass on re-examination only in the subject in which he had previously failed would lead the way to an enormous deal of scamping. Students would only prepare for one part at a time. He urged the Council not to go too far and emasculate the bodies, destroying their influence and position, and causing them to lose heart in the work.

Dr. HAUGHTON said he could not comprehend what the meaning of conclusion No. 11 was. He had been quite electrified by some of the fossil principles of examination that had been dug up. He knew what the nine Muses were, and what the three Graces were, but he could not understand what the four vetoes were. It would not be tolerated for one minute in the University of Dublin. He strongly ob-

jected to the resolution as being altogether an improper detail. In the Dublin University there was no such thing as an oral examination in addition to the written examination. The examination was essentially practical—in the dissecting-room, at the bedside, in the laboratory, &c. If that was what was meant by an oral examination, he considered it ten times more important than the written examination. If a man failed in the written, perhaps through nervousness, and then came up and passed a brilliant oral examination, he would be allowed to pass. He was also strongly opposed to passing men bit by bit, and he objected to the *morale* that dictated the resolution, which was the convenience of the examiners, and not justice to the candidates.

Dr. SCOTT ORR considered that going through the whole of an examination was a most valuable lesson to a man. Like Dr. Humphry, he had been struck with the improvement which rejected candidates had shown when they came up for their re-examination. Many candidates who were rejected in the written examination might go away with the feeling that they had not had justice done to them, because they might have redeemed themselves in the oral examination. He therefore could not support the resolution.

Dr. HALDANE protested against the resolution, because it dealt too much with detail, with which the Council had really nothing to do.

Sir WM. GULL considered that it was *ultra vires* for the Council to make arrangements for the economy of the time of the examiners.

Mr. TEALE, in reply, said the *morale* of the resolution was that the visitors pointed out a method by which the difficulties which it had been urged would be experienced in dealing with very large numbers of candidates, if certain details were adopted, might be avoided. He quite agreed with Dr. Humphry that taking the candidate through the whole examination was a kind of education.

Sir WM. GULL moved the previous question.

Dr. LYONS seconded it.

On being put to the vote the previous question was negatived, as was also the original motion, for which only two hands were held up.

Mr. TEALE next moved a resolution embodying the twelfth conclusion of the visitors, "In any future revision of the curriculum, the subjects of hygiene, ophthalmology, and mental disease will command serious consideration, and perhaps admission, under careful limitation, as distinct elements of examination." He thought it was quite clear that the general practitioner ought to know of specialties such portions as would necessarily come under his own treatment at first. For instance, he should be able to undertake a case of ordinary disease of the eye, in order to recognise such a subject as glaucoma.

Mr. COLLINS seconded the motion.

Dr. BANKS said there was no knowledge more necessary for a general practitioner than that which would enable him to decide upon a person's sanity or insanity. Ignorance on the subject might involve the letting a lunatic go at large, or the deprivation of a sane person's liberty. Two years ago this question was brought before the Council, but was shelved. No better example could be followed than that of the London University, which insisted on three months' clinical study in an asylum for the treatment of mental disease, and the Royal University in Dublin had placed a similar requirement in their curriculum. He therefore intended to move, "That in consideration of the absolute need which exists for the general practitioner of possessing a knowledge of mental disease, it be a recommendation of this Council that in any future revision of the examination rules the subject of mental disease be made a part of the examination."

Dr. HAUGHTON said he was prepared to second such a motion.

A long discussion ensued as to whether or not this could be put in as an amendment. Ultimately it was decided to separate the subjects of mental disease, ophthalmology, and hygiene, and to take a resolution on each.

Dr. TEALE proposed, "That it is desirable that the subject of mental disease should have serious consideration in any revision of curriculum and examination rules."

Dr. BANKS seconded the motion.

Mr. TURNER said he was more than doubtful as to the expediency of calling the attention of the medical authorities by resolutions of the Council to this or any other subject as a special one. It should be taken for granted that all such

subjects came within the scope of the study of medicine, and the good sense and zeal of the examining bodies would lead them to put as much into the examinations as they safely could with reasonable justice to the students.

Sir WM. GULL also thought that the object of the Council should be to secure a wide education for medical men, and it was undesirable to split up the subjects too much.

Dr. HAUGHTON said there were five medical authorities in Ireland, not one of which required any training in a hospital for the insane.

Mr. SIMON asked if it was the opinion of the visitors that, in general, mental diseases were not sufficiently examined in.

Mr. TEALE said he did not think the conclusion was drawn so much from anything that was observed, as from a desire to call attention to these points.

Mr. MACNAMARA said there would be great difficulties in some cases in obtaining facilities for the clinical study of mental diseases, and the Council ought to hesitate before making a recommendation which must afterwards be practically disregarded.

On being put to the vote, the motion was lost by 9 to 5.

Mr. TEALE said that the principle having been established by the Council in its vote with reference to mental diseases, he proposed to withdraw from its consideration the remaining matters referred to in the visitors' conclusions.

Mr. MACNAMARA moved, "That this Council note with approval the suggestion, so far as hygiene is concerned, by Dr. Gairdner and Mr. Stokes."

Mr. COLLINS seconded the motion.

Mr. SIMON moved as an amendment, "That, considering how important it is to all medical practitioners to possess a competent knowledge of hygiene and preventive medicine, the Council takes note of the suggestion of Dr. Gairdner and Mr. Stokes that these subjects ought to form a more independent part than they do of the examinations of all corporations."

Mr. TEALE, in seconding the motion, said, although he agreed with his colleagues Mr. Stokes and Dr. Gairdner that hygiene should be taken into consideration, he was not prepared to concur in their suggestion that the matter should now be pressed upon the different bodies as a subject of examination.

Dr. PETTIGREW thought that it would be undesirable to overburden the student with a new subject which might add another year to his period of study. The proper time to consider the matter would be when the curricula of the different bodies were overhauled, a work which would soon have to be undertaken.

Dr. LYONS suggested the omission of the words, "preventive medicine." He thought the term was very objectionable, as being loose and indefinite. A high authority like the Medical Council ought not to encourage *argot* of that kind.

Mr. SIMON protested against Dr. Lyons's description of the term "preventive medicine," which he said had been current for twenty years, and was perfectly well understood.

Dr. HAUGHTON opposed the motion and the resolution, and described the whole discussion on the question as a mere logomachy. In the University of Dublin a person could not have a certificate in State Medicine unless he was a Doctor in Medicine, or a Graduate in Medicine and Surgery of Dublin, Oxford, or Cambridge; and the subjects included law, engineering, pathology, vital and sanitary statistics, chemistry, meteorology, and medical jurisprudence.

The amendment was then put, and carried by 10 votes against 6. When put as an original motion, Dr. LYONS moved as an amendment the omission of the words "preventive medicine."

Dr. SMITH seconded the amendment, which on being put was negatived.

Mr. SIMON's amendment having now become the original motion, was then put to the vote and carried.

The Council then resumed, and on the motion of Dr. CHAMBERS, seconded by Dr. PITMAN, a committee was appointed on "Uses and Abuses of Unqualified Assistants."

Dr. HAUGHTON called attention to the fact that the Council had decided to take into consideration not only the report of the visitors, but the remarks of the corporations visited, and suggested that an opportunity should be afforded to the representatives of those bodies on the Council to make any observations they might desire to offer on the report.

Sir WM. GULL thought it would be a waste of time to go over the ground again, and said that every opportunity had been afforded to the representatives to make any remarks upon the report of the visitors.

Dr. SMITH expressed a hope that the Council, for the sake of its own credit, would not refuse an opportunity to the

representatives of the bodies visited of making observations on the report of the visitors.

Dr. LYONS moved, "That Order No. 3 (the motion of Dr. Haughton for the consideration of the visitors' report and the remarks of the corporations) be discharged."

The PRESIDENT said that upon that motion the representatives of the bodies visited would have an opportunity of making any remarks upon the visitors' report.

Dr. SMITH called attention to the remark made by the King and Queen's College of Physicians, Ireland, with regard to Part III. of the Report, "That the College have only to remark, with regret, the absence of specimens of the answers given by the candidates to the questions printed with the other examination documents of the College." It appeared from the visitors' preface that they had not printed any of the written answers, not feeling that a commensurate advantage would result from the publication of such a large mass of manuscript, but they had collected the answers, or copies of them, selected from the examinations of each body which had been placed in sealed packets among the archives of the Council. As the answers had not been printed, he thought that the visitors ought to have given the Council some information with regard to them, and especially to have stated whether the answers to which they had referred, as showing a defective education, had been taken into account in passing of the candidates.

Dr. HALDANE referred to the statement of the visitors in the preface of their report, "They have refrained from expressing opinions on the judgment formed by the examiners in passing or rejecting candidates, feeling that such judgments ought to rest solely with those who are responsible for the examination; and moreover, that the standard of any examination cannot be fairly taken from the individual opinion of the examiner, especially when given in the presence of visitors, who have to report critically upon the examinations." If the view of the visitors were correct he thought there was no use in having visitations at all. Their object was to discover the weak points in the examinations of the candidates in order that they might be laid before the Council, and an opportunity be given to the different bodies to correct their errors. There were several errors in the report of the visitors to which he desired to allude. With reference to the question as to whether examiners were elected to examine in special subjects, the visitors said with regard to the Royal College of Physicians, Edinburgh, "to a certain extent—i.e., after elections are assigned to special groups of subjects"—that statement was not correct, the examiners being elected purely for their special knowledge in different subjects. The visitors further stated, "The examination for the double qualification of the Glasgow Faculty pertains also to that of the College of Physicians of Edinburgh, but of this examination the 'primary' witnessed by the visitors was conducted almost exclusively by the Glasgow examiners, those from Edinburgh acting simply *pro forma*." That also was an inaccurate statement, an equal share being taken by the Edinburgh and Glasgow examiners. The visitors were further in error in stating that at the College of Physicians examination in the double qualification there was no practical examination in chemistry. There were several other points on which the visitors had been led into error, but they had been referred to in the printed remarks of the different bodies.

Dr. WATSON said it was the duty of the visitors to inquire into and report to the Council as to the efficiency of the examination conducted by the several licensing bodies as to the candidates' fitness to obtain their respective qualifications, and he desired to ask the visitors, with reference to the college which he represented (the Royal College of Surgeons of Edinburgh), whether the tests employed by that body were sufficient for that purpose. He failed to find any such answer in their report. They had stated that "the visitors feel bound to notice certain respects in which the examination (of the Royal College of Physicians of Edinburgh) appeared to fall short of the requirements considered necessary by other examining boards that they have inspected." Either they had not the courage of their opinions or they wished to put the matter in such a way that they could not be made responsible for what they said. The visitors had been required to inspect certain bodies in Scotland, but so far as he could ascertain they had not visited the examination of the Royal College of Surgeons, though they had received information as to when it was to take place. He wished to know the meaning of the statement of the visitors that "at the Royal Colleges of Physicians and Surgeons, Edinburgh, the

very questionable practice still prevails of framing at the beginning of the year the questions for the written part of the several series of examinations," and also of the statement that "in the arrangements for each examination the written answers are read and decided upon by the examiners, who may not have been responsible for the questions put, and the *read voce* part is conducted by different examiners, who may, and often do, ask the same questions as have already been given in writing." With reference to the first statement, he might remark that what the visitors condemned in connexion with the Edinburgh College they praised to the skies in connexion with the London College of Physicians; and in regard to the second statement, he had not been able to find in the report the faintest trace of anything to support the allegation. He might be permitted to mention an absurd error made by the visitors in regard to one of the patients brought under the notice of the candidates. The case was one of hard chancre, but was referred to by the visitors as a case of rupial eruption.

Mr. TEALE said he was the only visitor in the Council, and he did not therefore feel himself in a position to answer the statements that had been made before consulting with his colleagues. He might mention, however, with regard to the question of printing the answers of the candidates, that the cost would be very considerable, and that there were so many difficulties in the way, that the visitors had thought it better to have the papers preserved for the inspection of the Council if required.

Dr. Lyons' motion was then passed, and the Council adjourned.

#### TUESDAY, JULY 4TH.

The whole of the sitting was occupied by the Council on the consideration of the case of David Beatson Murdoch, in regard to whom a communication had been received from the Medical Alliance Association requesting that his name should be removed from the Medical Register "for disgraceful conduct in the practice of his profession." Mr. Murdoch attended before the Council and was examined by Mr. Farrer, the Council's solicitor, with regard to his employment of unqualified practitioners. The Council deliberated in private for three hours, and when strangers were readmitted the President announced to Mr. Murdoch that the Council judged him to have been guilty of infamous conduct in a professional respect, but did not now direct the Registrar to erase his name from the Register, on the ground that he had undertaken to discontinue the acts complained of.

#### WEDNESDAY, JULY 5TH.

The first subject taken into consideration was the communication from the South Australian Branch of the British Medical Association with regard to the case of Mr. Hartley Dixon. After hearing the explanation by Mr. Collins of the circumstances under which the Apothecaries' Hall of Ireland granted their licence to Mr. Dixon, the Council resolved: "That it is unnecessary to take further steps in the matter." In the matter of George Stratten Symmons, who had petitioned the Council to restore his name to the Register, a discussion arose as to whether the Council had power to comply with the petition, and the opinion of counsel on the subject was ordered to be taken.

The name of William Story was ordered to be erased from the Register, he having been convicted in October last at the Bedford Assizes and sentenced to penal servitude for five years for setting fire to a house in his possession.

The remainder of the sitting was occupied with the consideration of the Dental Register. The Dental Association had requested the Council to erase from the Register the names of certain persons who, it was alleged, were not legally entitled to call themselves dentists; but the Council decided that they were not prepared to comply with the request of the Association.

#### THURSDAY, JULY 6TH.

The Council spent some time in considering the report of the Committee of the whole Council on the report of the visitors of examinations. The first seven clauses of the report were adopted with slight alterations; the clause relating to additional time at oral examinations, and the clause respecting hygiene and preventive medicine, were not adopted in the form of positive recommendations, but the attention of the corporations was directed to them, and also to the subject of mental disease. A motion made by Dr.

Pitman, to the effect that persons whose names were struck off the Register under Clause 29 of the Medical Act should *ipso facto* forfeit any medical titles which they might hold from any of the medical authorities was, after some discussion, withdrawn. The remainder of the sitting was occupied with the consideration of a motion by Dr. Smith with reference to an application made by the King and Queen's College of Physicians in Ireland respecting one of its licentiates, who, it was stated, had been improperly accused of malpractice by a fellow-practitioner. Complaint was made that the English Branch Council had not made due inquiry into the matter; and it was resolved that it should be referred to that body for further consideration.

A fuller report of Tuesday's, Wednesday's, and Thursday's sittings will appear next week.

### "THE OPERATION OF 'SPAYING' IN WOMEN."

To the Editor of THE LANCET.

SIR,—I have read your correspondence with Mr. Lawson Tait with much interest, and, as bearing on the point at issue, may I recount my experience with Mr. Lawson Tait not three months ago? And I may add that Dr. Webb of Wirksworth was cognisant of the position Mr. Tait took, and also witnessed the operation, and saw the patient's ovaries after removal.

Mrs. A—, widow, aged thirty-eight, had suffered continuously for twelve years from the distressing physical and mental symptoms of what one physician termed spinal irritation, another aggravated hysteria, another chronic ovaritis, but all in turn, including myself, failed to do her any good. She was thoroughly wretched, and being a sensible and a Christian woman felt her enforced dependence on her brother and her entire inability to carry on her little shop very deeply. I felt certain the source of all her trouble lay in the ovaries, and with a fully descriptive letter I sent her up to Mr. Tait, with the recommendation that he should watch her condition for a time before forming an opinion. This he did, and wrote to me, "I cannot find anything wrong with the uterus or appendages; you had better come up before I send her back. I cannot operate, as I do not see any justification for doing so." In consequence of this I went to Birmingham, and told Mr. Tait that I felt sure the removal of the appendages was the only thing that would benefit her. He still refused to operate unless I would take the entire responsibility of the procedure, which, after a consultation with her friends and herself, I agreed to do. The operation was performed the following morning, with the result of finding the tubes impermeable and bulging with puriform fluid and the ovaries partially filled with inspissated pus. The patient has recovered well from the operation, though slowly; but notwithstanding the second recurrence of her menstrual period since the operation, she expresses herself as feeling less excitable and mentally wretched, and I have every hope that when the uterine function wholly ceases, which it probably will in a few months, she will improve more rapidly and decidedly.

Now, in fairness to Mr. Lawson Tait, you must admit that, had he such a proclivity for "spaying," as you suggest, he would not have refused to operate in the case I have described. Nothing could be more defined or decided than the position he took.

As an interesting incident in relation to these prolonged, distressing, and obscure cases, I well remember some years ago a farmer's wife suffering from a set of symptoms very similar to those of Mrs. A—. She was ill several years, and went from one doctor to another, and at last died under forty years of age. I remember distinctly asking the gentleman under whose care she was at the last what was the matter with her. He replied, "We had a post-mortem, and found her ovaries full of cheese-like pus, nothing else."

I am, Sir, faithfully yours,

Milford, Hants, July 8rd, 1882.

DOUGLAS W. ESHELBY.

\* \* We would call attention to the fact that Mr. Tait removed the ovaries of a patient of whom he said, "I cannot find anything wrong with the uterus or appendages. . . . I cannot operate, as I do not see any justification for doing so." And, to quote Dr. Eshelby, "He still refused to operate unless I would take the entire responsibility of the procedure."—ED. L.

# THE LANCET.

LONDON: SATURDAY, JULY 8, 1882.

THE more the Report of the Royal Commission is studied, the more will it be valued as a contribution to sound legislation. It not only recommends the unification of the licensing authority in each division of the kingdom, and the representation of the individual authorities of each division in a Divisional Board, but also proposes a very material change in the constitution of the Medical Council. Our readers are aware that the present Council consists of twenty-two members and the President chosen by the Council from without. The twenty-two members represent respectively the medical authorities and the Crown. Each medical authority, excepting the four Scottish universities, which have only two representatives among them, sends one representative to the Council, and there are in it six gentlemen representing the Crown. The Royal Commissioners propose to reduce the number of the Council from twenty-two to eighteen. It is but logical, when combining the licensing authorities into one, to do away with their individual representation in the General Medical Council. Accordingly, the Commissioners propose that the Divisional Boards in which every medical authority, or every surviving medical authority, is to be represented, shall choose eight of the members of the new Medical Council to represent them—that is to say, four to be chosen by the English Divisional Board, and two by the Scotch and Irish Divisional Boards respectively. In this way, instead of having seventeen representatives in the Council, the medical authorities will have only eight. The Crown will have six, as at present, and the profession is to have four. The profession, and the public too, will cordially appreciate the view of the Commissioners, very boldly and earnestly expressed, that whilst the Council exists mainly in the interest of the public, its constitution is a matter of vital interest to the whole medical profession. The paragraph of the Report on this subject is so outspoken, and destined, we trust, to have such important consequences, that we give it in full:—

“The direct representation of the profession upon the Medical Council is a question which has been so long and fully argued that we feel it unnecessary to enter upon it further than for the purpose of expressing our conclusion. While we insist that the reason of the existence of the Medical Council is the interest of the public, we cannot but recognise the vital interest of the whole medical profession in the constitution of that body. It seems to us highly important that the profession should have full and complete confidence in the Council, and, seeing that the governing bodies of the medical corporations which now elect members of the Council can hardly be said to represent the great majority of practitioners, we think it advisable to give the general practitioner an effective voice in the body which will be the principal authority of the medical profession. We see no reason to suppose that the members elected by direct representation will be less eminent than those nominated either by the Crown or the divisional boards.”

Such a view of the relation between the Medical Council and the medical profession must commend itself to all medical men who have not learned to look on the profession from the eminence of a corporation like the Medical Council, which, deriving its chief importance from the profession, whose education and registration it supervises, seems to regard its members with very scant respect. It is pitiable to see a man like Mr. SIMON disparage and, as we think, seriously misrepresent—of course unintentionally—the nature of the demand for the representation of the profession in the Council, and to see him joined by Professor TURNER. Their position of Commissioners might have deterred them from taking the action of witnesses and reproducing old and ten-times-answered arguments. When the evidence has been published, the Government and Parliament will have an opportunity of judging how far Mr. SIMON'S representations of the motives and objects of those demanding the representation of the profession, as distinguished from its corporations, is justified, and we very much mistake if they do not come to the conclusion that the Medical Council is a very self-complacent body, and that Mr. SIMON and Professor TURNER have the complacency and the conservatism of the Council in a very pronounced form. The Government will not fail to notice that the report in favour of direct representation has all the support that Sir WILLIAM JENNER can give it, who is in far more direct contact with medical practitioners and with the public than either the learned anatomical professor or the somewhat unsympathetic ex-medical officer of the Privy Council. The Royal Commissioners not only intend the future Council to enjoy the confidence of the profession, but of the public. It is not to be a weak “recommending” body like the present. But is to have “supreme authority” and “larger powers” than it has hitherto possessed. It will have power to vary or annul any resolution of a Divisional Board, and it will be its duty to ensure as far as possible equality in the curriculum and examination between the three Divisional Boards.

The report of a Commission that has so grasped the great questions of medical reform, and that has besides recommended the entrustment of prosecutions under the Medical Act to the Public Prosecutor is not to be lightly esteemed. Despite the conservatism of Mr. HUXLEY, and of Mr. SIMON and Professor TURNER, changes like those suggested by the Commissioners must take place. Mr. MUNDELLA will not be deterred, with the support of Lord CAMPERDOWN, Mr. COGAN, Sir GEORGE JESSEL, Sir WILLIAM JENNER, and Mr. McDONNELL, from proposing changes which are mainly resisted by members of existing bodies. Never yet have bodies been reformed from within. Never yet have their members seen the necessity of changes till they were accomplished against their will. The time has come now to act independently. Government cannot evade the duty, if it would, of teaching the medical corporations that they exist for the public, and that they cannot longer be permitted to compete in lowering the standard of medical education.

It was generally understood that the *magnum opus* of the Medical Council at its recent meeting was to be the Report of the Visitors, and the discussion on it. There were sub-

stantial reasons for thinking so. The Visitors were men of the highest capacity for the work. They visited, or had a commission to visit, all the corporations of each division of the kingdom—those examining bodies, it will be noticed, that are reputed to be so different in their standard, and yet in whose substantial uniformity of standard the public and the profession have so great an interest. The President has told us they were not to be hindered by economical considerations, and were to avail themselves freely of any clerical assistance. The financial facts connected with the Report justify the expectation with which it and the discussion of it have been regarded. As we said last week, the Report itself has taken about £1500 out of the funds of the Council. The discussion of it has extended over four or five days, or parts of days, of the session of the Council. We shall not be far wrong in supposing that, as the Report itself cost £1500, the discussion of it will cost £500 or £600 more—in all over £2000. Will anyone say, regarding either the Report or the discussion, that we have value received? We are tempted to say that if three advanced students had gone to visit the examinations and to report, we should have had a more practical report than the one we have got. The discussion in the Council took the form of a debate on thirteen abstract conclusions of the Visitors. On one or two of these some really pertinent and important speeches were made: notably that of Professor TURNER on the impracticability of the conclusion of the Visitors that every candidate should be required to dissect with the present limited supply for anatomical purposes; and that of Mr. MARSHALL on the conclusion of the Visitors against a sharp limitation of time in examining candidates. In the case of one or two of the conclusions of the Visitors, the Council, after discussing them for a length of time, discovered or remembered that they were already part of their published Recommendations. The Report points out, in the case of most of the bodies, Recommendations of the Council or of previous Visitors which have not been adopted.

We must confess to a feeling of considerable disappointment with the Report, or at least with the inadequate way in which the comparative efficiency of the examinations of the several corporations has been represented to the Council. The public had a right to expect to be plainly informed whether the often-alleged differences of standard between the examinations in London, Edinburgh, and Dublin, really exist. It may be true that they are implied or insinuated in the reports. We think that careful readers, or those who know how much is meant by the euphemistic phrases of the Council and its Visitors, will see that very grave differences of knowledge are accepted as satisfactory by different bodies which ought to do substantially the same work. But this has not been made manifest. Mr. MARSHALL elicited the curious fact, already brought out by Dr. GLOVER before the Select Committee of the House of Commons, that the College of Surgeons of England rejects a far smaller percentage of candidates than the Scotch Corporations. But nobody believes that the standard of examination is higher in the conjoint examinations of the Scottish corporations than in the examination for the membership of the English College. This great and costly visitation of the corporations in all divisions of the kingdom can only be justified by a full and explicit statement by the Visitors, as Dr.

HERON WATSON very properly said, of their opinion of the sufficiency of the examinations. It is only due to Dr. WATSON, as the representative of the Edinburgh College of Surgeons, to say that he challenged Mr. TEALE to express such an opinion as regards the examinations of his own College; but Mr. TEALE declined, without consultation of his colleagues, to do so. Meantime the Edinburgh corporations suffer, notwithstanding a very smart retort upon the Visitors, under such disparaging remarks as these: that in the opinion of the Visitors the major part of their anatomical examination consists "of questions of too elementary a character," and that eight examiners form a judgment of ninety-six papers in Anatomy, Physiology, and Chemistry in less than an hour.

The euphemistic style of the Visitors reaches its climax in the Report on the Examination of the Apothecaries' Hall of Ireland. We commend it as a study in this kind of writing.

AN almost untouched field has been explored by NOTH-NAGEL in his latest study of intestinal function. Of the effect of various chemical substances on unstriated muscle we know almost nothing, and this has been the subject of his investigations, the results of which are of great interest as well as of novelty. The investigations were made on etherised rabbits, the open abdomen being immersed in a warm neutral solution, and the substance to be tried was gently placed, in a solid form, on the external surface of the bowel. It was previously ascertained that the mechanical irritation thus caused was too slight to produce any effect on the muscular tissue.

The first important fact ascertained was that there is a fundamental difference in the action of potash and soda salts, and that this difference depends on the alkali, being irrespective of the combination in which the alkali happens to be. However similar, for instance, in general action is bromide of potassium to bromide of sodium, there is a marked contrast in their effect on the intestine, due to the basic alkali. If a salt of potash is placed on any part of the bowel, large or small (the cæcum for the present being excluded), a strong muscular contraction results, which remains limited to the part touched, or merely extends around the intestine in an annular form. On the other hand, if a soda salt is employed, a contraction is produced which does not remain limited to the spot, but extends from it for several centimetres, and always upwards, towards the pylorus. The result is uniform in cats as well as in rabbits, and there is no reason to suppose that it is not true also for the human intestine. The fact may sometimes be of use to operators. If, for instance, a small piece of the bowel is exposed and it is desired to know which is the upper and which is the lower portion, all that is necessary is to place upon it a fragment of common salt—a perfectly harmless proceeding—and a contraction will occur, and will pass invariably upwards.

The contraction produced by potash, although so limited, is very energetic, completely emptying the bowel at the spot, and the local contracted part may be concealed, being overlapped by the adjacent uncontracted part, so abruptly limited is the contraction. The local contraction does not seem to set up actual peristaltic action, any slight movement of this character which is observed being apparently due to the distension of the bowel above by the

interference with movement of the contents. In order to produce the contraction, the potash salt need not remain in contact more than from half a second to one second, and the interval between the commencement of contact and of contraction is from one-eighth to six-eighths of a second. The contraction always begins at the spot touched. On the other hand, in the case of the soda salts, the contraction sometimes begins at the spot touched, but very often a few millimetres higher up, the spot actually touched remaining uncontracted, a phenomenon never observed with potash salts. The contraction then extends upwards as already mentioned, until six or eight centimetres of the intestine may be reduced to a pale empty cord. The constriction lasts from five to thirty seconds, and then goes off gradually with some slightly irregular peristaltic waves. The duration and intensity of the effect seem to depend to some extent on the degree of irritability. Below the point of application the bowel is for the most part still. The application of the soda salt to the cæcum has almost no effect. A very short application of a soda salt to any part, for less than one second, often has no result. The application has usually to last for two or three seconds. The latent period before contraction begins is from two to ten seconds. The contraction does not last so long as that which is produced by the potash salt. Experiments on cats yielded similar results, the only difference observed depending apparently on the greater development of muscular tissue in the intestine of the cat.

Observations on the action of other substances showed that only ammonium compounds produce the same effect as the soda salts—i.e., an ascending contraction. All other substances examined have a different effect. Common alum causes a slow and comparatively feeble contraction, remaining limited to the point to which the stimulation was applied. The effect of magnesian chloride and sulphate is uncertain; sometimes they cause a local contraction, sometimes none at all. Chloride of calcium produces a somewhat stronger contraction than chloride of magnesium, but sulphate of copper, chloride of silver, and acetate of lead, produce only a local contraction, which comes on slowly and lasts a long time, often several minutes. Sugar and urea have no effect. It is very remarkable that the action of the sulphates of potash, soda, and magnesia, when applied to the outside of the bowel, should be so widely different, although each produces the same effect when taken internally.

In considering the mode in which the effects were produced, only the effects of the compounds of potash and soda were considered. The first question was whether the contractions were to be regarded as the direct result of the stimulation of the muscular fibres, or as the effect of the excitation of any nervous elements. The local character of the contraction produced by potash makes it probable that the action is the result of the local stimulation of the muscular fibres. NOTHNAGEL believes that the soda salts exert an influence, although feebly, on the muscular fibres, but it is very difficult to decide whether the special ascending contraction of the soda salts is or is not due to a nervous mechanism. That it is, is suggested by the striking difference from the contraction produced by the potash salts. Experiments showed, however, that the contraction occurs even when the nerves of the mesentery have been divided, and the only nervous mechanism which could co-operate in pro-

ducing the contraction is the ganglionic arrangement in the wall of the bowel itself. That it does depend on this mechanism is probable from the considerations, first, that the contraction begins not at, but a little above, the point touched; secondly, the longer latent interval; and thirdly, the fact that after the post-mortem peristaltic action has ceased, potash salts still cause the local contraction, and a similar contraction can sometimes be caused by soda, but never the characteristic ascending contraction.

A large number of experiments were made on other organs which are furnished with involuntary muscular fibres, under the same conditions. In the bladder the soda salts caused only a feeble and local contraction, while the potash salts had a much more energetic effect, producing an alteration in the shape of the bladder and not unfrequently the expulsion of some of its contents. Applied to the stomach both salts cause only a local contraction, which is sometimes absent when the soda salt is used. Neither caused any appearance of peristaltic waves. These results show that the potash salt has a more energetic local action on the bladder and stomach than the soda salt, and agree with effect on the intestine if the ascending contraction, observed in the latter, is regarded as produced through the nervous mechanism, and to this view they therefore give indirect support. How this local stimulation is produced is, however, obscure. That it is not due to the simple withdrawal of water is evident from the trifling effect of the chlorides of calcium and magnesium. Still more surprising and mysterious, however, is the remarkable fact that the contraction produced (probably through the nervous structures) by the soda salts should pass invariably upwards. The fact is one which cannot be correlated with any other known facts in the physiology of the intestine, and it affords a glimpse into a class of phenomena of which at present we apparently know nothing.

SOME few weeks ago we called attention to the serious condition of the colonial medical service in British Guiana, which had led to strong expressions of opinion in the local press. Since that date we have received further information, which not only confirms that on which we previously acted, but has furnished us with some of the reasons for the disastrous state of the service. Among these we may mention the following. The medical officers are under the control of the Governor of the colony, and are liable to instant dismissal by him without any right of appeal or protest, and in this respect they are worse off than any other civil officer of the Governor. The statistics to which we have previously referred show that Governors have hitherto not been slack in exercising this "privilege." But a still greater source of difficulty is the fact that the medical officers are allowed no independence of action, and are continually hampered in the discharge of their duties by managers of estates and others, who at times regard them as beneath all consideration. Even in the hospitals to which they are attached, and for the proper and successful conduct of which they are responsible, they are not their own masters, but are subjected to constant interference and grave annoyance by lay authorities, managers, and so forth. The climate of Demerara greatly taxes the health and endurance of Europeans, and those who are actively engaged

with such anxious and exhausting duties as those discharged by the colonial medical officers need opportunities of visiting more temperate and healthy climates at short intervals; but even this meagre measure of justice is withheld or given tardily, grudgingly, and with ill grace. The leave of absence should be a matter of right after but a short service; but the present arrangement is that none is due until after five years, and it may then be postponed or withheld by the head of the medical department if his personal feelings so incline him; and even when the leave of absence is at last granted, its recipient has to forego half his pay. Again there is no security against change, and the medical officers of the service are liable to be sent from one part of the colony to another at the shortest notice, and no allowance is made for the serious expense and inconvenience to which they are exposed. Happily the public press is interesting itself in the case of the medical men, and there is therefore some hope that the complaints may reach official ears. But it is evident that the whole subject demands a full and searching inquiry, and that the medical service of the colony must be put on a better basis. It needs a strong man at its head, commanding the respect of all parties; and the medical officers should be freed from all petty annoyances, frequent removals, and the interference of laymen in their own special sphere; they should also have leave of absence assured to them after three years' service. While the service is in its present disorganised state, we cannot recommend anyone who values his independence of action, or has any wish to uphold the dignity of his profession, to enter this colonial service. A "strike" of candidates is probably the only form of pressure that will tell upon the authorities, who, by their indifference to the complaints and representations of those who have entered their service, seem to show that, so long as there are men to fill the vacancies as they arise, they have no interest in the welfare of their servants. Unless some distinct improvement is soon accomplished, the colonial authorities will, however, find themselves in an unenviable predicament.

## Annotations.

"No quid nimis."

### THE MEDICAL COUNCIL AND SHAM DISPENSARIES.

THE Medical Council has woken up at the eleventh hour. It perceives thus late that it has some duties in connexion with the moralities of medical practice. We shall not determine who is to blame or who is to be praised in connexion with this late display of usefulness on the part of the Council, whether the Medical Alliance Association (which has displayed a creditable amount of energy and public spirit in exposing the working of so-called provident dispensaries in the east of London), or Mr. H. Samuelson, who put a question on Mr. Murdoch's case in the House, or the Home Secretary who answered the question, and in doing so referred Mr. Samuelson to the Medical Council, which, he said, has power to act, by the 21st & 22nd Victoria, in such cases. The Home Secretary further advised Mr. Samuelson to ask the Medical Council to put the Act in force against registered practitioners acting as in this case. As the Medical Council has generally been deaf to the voice of the profession when asked to vindicate professional morality,

most people will be apt now to think that, apart from the magic influence of the words of the Home Secretary, we should have heard nothing in the Council of Mr. Murdoch and his now victorious assistant, "the black doctor," *alias* Colonel Griffin, or "Governaur Hamilton Griffin," who, though entirely without medical qualification, played such a large part in the treatment of cases supposed to be under the care of Mr. Murdoch, and who was also Mr. Murdoch's landlord. Our readers are aware of the main facts of the two cases which were fully brought out at two inquests before Sir John Humphreys. There were really three cases: Naomi Chatfield, Martha Elizabeth Bailey Chatfield, and Henry Arthur Parker. Griffin had been in attendance on Naomi. The parents and friends thought him a qualified doctor, for whom they "had sent to the provident dispensary." When Naomi was dying "the Colonel" sent for Mr. Murdoch. He came, and the child died as he came in. The certificate was in Mr. Murdoch's writing. On this occasion Mr. Murdoch saw Martha Chatfield, but never afterwards. When she died a certificate of death was handed to the parents by Griffin with Mr. Murdoch's name attached. Mr. Murdoch alleges this was a forgery. The facts of the death of the third child, Henry Arthur Parker, are that twice out of thrice it was seen by "the dark gentleman," once by Mr. Murdoch. A certificate was given, which Mr. Murdoch said he had not authorised.

There is much reason to believe that there are too many practitioners in London who, like Mr. Murdoch, have three or four dispensaries, at considerable distances from each other and from the residence of the principal, worked by unqualified assistants whose names even are unknown to the people whom they attend, who take them for the principal whose name covers and protects the whole arrangement. The gentlemen who are in Mr. Murdoch's position will perhaps take warning by what has happened. The Medical Council have stopped short of erasing Mr. Murdoch's name from the Register. But it may be assumed that, after this warning and the sharp call of the Council to duty by the Home Secretary, they will not deal so tenderly with any similar case that may come before them.

### THE CHAIR OF SURGERY IN EDINBURGH.

THE vacant Chair of Surgery in the University of Edinburgh will, we understand, be filled up on July 17th. The appointment is in the hands of the Curators, three of whom—viz., Sir Alexander Grant, Mr. Campbell Swinton, and the Hon. Lord Kinnear,—are elected by the University, four of whom—viz., the Right Hon. Sir T. I. Boyd, Lord Provost, Mr. John Boyd, Mr. Duncan McLaren, and Mr. James Colston,—are elected by the Town Council of Edinburgh. The candidates are Mr. Joseph Bell, Mr. Chiene, Dr. John Duncan, and Dr. P. Heron Watson.

Mr. Joseph Bell graduated as M.D. Edin. in 1859. After acting as resident surgeon under Professor Syme, and resident physician under Professor Gairdner in the Edinburgh Royal Infirmary, he acted for two years as demonstrator of anatomy under Professor Goodsir. For seventeen years he has been a member of the surgical staff of the Royal Infirmary, and is now senior acting surgeon. In the year 1863 he commenced to lecture on surgery, and continued to give a systematic course in the Extra-Mural School until 1878, when he became senior surgeon. He then, in accordance with custom, gave up his systematic course to conduct a qualifying course of Clinical Surgery. Mr. Bell is the author of "A Manual of the Operations of Surgery," and of numerous papers in the *Edinburgh Medical Journal*, of which he is the editor. He is engaged in extensive practice, both medical and surgical.

Mr. Chiene graduated as M.D. Edin. in 1865. He acted

for twelve months as house-surgeon to Mr. Syme, and acted for four years as demonstrator of Anatomy under Professors Goodsir and Turner. Since 1875 he has held the office of additional examiner in anatomy in the University of Edinburgh. He is one of the acting surgeons to the Royal Infirmary, Edinburgh. Since 1870 he has given a systematic course of lectures on Surgery in the Extra-Academical School, the average attendance at which has been 107 students. He is the author of an illustrated work on Surgical Anatomy, of a series of Lectures on Surgery, which have been published in the *American Practitioner*, and of numerous papers in the various medical and scientific journals. From an early period of his career he has devoted himself to pure surgery.

Dr. John Duncan graduated as M.A. Edin. in 1858 and M.D. Edin. in 1862. After acting for a year and a half as house-surgeon to Prof. Syme he spent two years in the continental schools. He then succeeded to a considerable portion of his father's practice, which soon became one of the largest in Edinburgh. "Finding, however, that, although an invaluable training, its increase began to interfere with surgical work, and being relieved from the necessity of pursuing it, he abandoned general practice; and for many years he has confined himself strictly to surgery." In 1865 he began to teach as demonstrator of anatomy under Dr. Handyside; and he then initiated a course of surgical anatomy and operative surgery—a course which he subsequently conducted at the request of Professor Goodsir in the University. In the year 1871 he commenced lecturing on systematic surgery in the Extra-Academical Medical School. His classes have annually increased in numbers; and last winter he enrolled one hundred and forty students. He is one of the acting surgeons to the Royal Infirmary, Edinburgh; is the author of a series of Essays on the Application of Electricity in Surgery, and of numerous other papers on surgical subjects.

Dr. P. Heron Watson graduated as M.D. Edin. in 1853. After acting as house-surgeon to the Edinburgh Royal Infirmary he became assistant-surgeon in the Royal Artillery, and was for some time engaged in active service. Soon after his return to Edinburgh he was appointed to the staff of the Royal Infirmary, and commenced to lecture on systematic surgery. He is an ex-President of the Royal College of Surgeons of Edinburgh, and was recently appointed the representative of the College in the General Medical Council in the room of the late Professor Spence. Dr. Watson is surgeon to the Royal Infirmary and to Chalmers Hospital, Edinburgh, and for many years has enjoyed one of the largest practices, both medical and surgical, in Edinburgh. He is the author of "Excision of the Knee-Joint in Cases of Disease or Accident," "The Modern Pathology and Treatment of Venereal Disease," and numerous papers on surgical pathology and therapeutics.

We have reason to believe that Dr. William Macewen is not a candidate for the Chair of Surgery in the Edinburgh University.

#### MUSEUM OF THE ROYAL COLLEGE OF SURGEONS.

PROFESSOR FLOWER'S annual report of the Museum of the Royal College of Surgeons is ready. Sir James Paget, with Dr. Goodhart and Mr. Duran, have been working on the new catalogue of the Pathological Collection. The whole of the M.S., including revised descriptions of nearly 5000 specimens, of which 1500 have been added since the publication of the last edition, is completed. The first volume, containing a description of the preparations illustrating General Pathology, will be ready for distribution in a few weeks. We have also to congratulate the Council on the nearly finished catalogue (Part 2) of the Osteological Col-

lection. Some of the finest additions to this collection—as the great elephant seal of the South Seas, and its allied species, the sea bear—have already been noticed in THE LANCET. The collection of human skeletons and skulls continues to receive large additions—notably a series of upwards of 100 skulls from Egypt, mostly those of mummies, presented by Captain R. C. Burton. Professor Flower regrets that it is not possible to ascertain the precise date of any of these skulls, yet many valuable indications may be gained from them relating to the general physical characters of the people to whom they belonged. The appeal made a few years ago by Sir Joseph Fayrer, F.R.C.S., to the medical officers of the army serving in India, to collect skeletons and crania of various Oriental races, has been liberally responded to, especially by Surgeon-Major Mackenzie, M.D., of the Campbell Hospital, Calcutta, who has forwarded eight perfect specimens to the Museum; Deputy Surgeon-General John Shortt, M.D., of Madras; Surgeon-Major G. Bidie, M.B., Superintendent of the Government Central Museum, Madras; Mr. Ondaatje, Colonial Surgeon, Ceylon; and Mr. R. S. Nariman, Civil Surgeon, Dohad. The Collection of Surgical Instruments, in which the late Sir William Fergusson took such a warm interest, has been enriched by Mr. Charles Hawkins, another ex-member of the Council, who has presented a series of about twenty-four instruments, which formerly belonged to the late Sir Benjamin Brodie, exhibiting progressive modifications in the methods of removing calculi from the bladder without the use of the knife. Dr. Jamieson, of Shanghai, has also presented some curious trusses of native manufacture. It is stated that as many as 11,234 visitors signed the hall porter's book during the past year, against 3669 in 1861.

#### THE TREATMENT OF FRACTURE OF THE SKULL WITH DEPRESSION.

It is not improbable that in the operative treatment of injuries and diseases of the skull some of the most important advances in surgery in the immediate future will be made. We now operate freely on deformed bones and diseased joints: operations on the abdominal viscera are now undertaken which but a few years ago were looked upon as altogether beyond the bounds of the practicable; and the therapeutic advances that have made these procedures so successful may be equally well applied to the surgery of the head. But accuracy in diagnosis is an essential condition of successful treatment, and as the recent discoveries of the special function of individual portions of the surface of the brain are rendering exact diagnosis of superficial brain lesions possible, it is not rash to foretell that surgery will keep pace with the science of diagnosis. The surgical treatment of depressed fracture of the skull has been formulated into the proposition that when accompanied with evidence of compression of the brain an operation to remove the depressed bone should be undertaken at once. This is the general if not the universal practice among British surgeons. But latterly some inclination to extend the use of the trephine has shown itself in more than one quarter. The reasons for this extension are that the operation, when properly conducted, and especially when carried out with due precautions against septic infection of the wound, is not a very dangerous one, and if we may argue from Dr. Yeo's experiments on monkeys to man, we may say that the use of the trephine adds very little, if at all, to the gravity of a case. Again, surgeons from time to time see cases where the results of a post-mortem examination show that a life might have been saved by a timely use of the trephine. In Paris the doctrine was first promulgated that the trephine ought to be used in *all* cases of compound fracture of the

vault of the skull, whether actual depression of bone, or symptoms of compression, be present or not. And lately in America it has been urged by Dr. Gunn that in all cases of depressed fracture, with or without symptoms of compression, and whether simple or compound, the depressed bone should be elevated. While we fully believe that the operation of trephining has fallen into undeserved disrepute, and might with advantage be resorted to more freely, we think that Dr. Gunn's proposal is unsound and dangerous. It is a familiar fact to any surgeon of large experience that patients who have received depressed fractures go through life quite unaffected by them, and while such is the case no appeal to cases in which the course of events is different ought to induce a surgeon to submit all cases alike to operation. For there is not conclusive evidence before us that the evil effects of depressed fractures, which often arise, may, without giving rise to symptoms, advance to such a degree as to render trephining useless. There appears, then, to be no sufficient ground for formulating the rule of practice otherwise than as at present, but it should be more liberally interpreted, close watch for symptoms of local mischief should be kept up, and the trephine resorted to as soon as any such symptoms declared themselves, even though slight, and with strong hopes of a successful issue, instead of, as at present, looking upon it as a *dernier ressort*, and using it timidly and with gloomy foreboding.

#### STERILITY.

THIS subject has been again and again brought before our notice of late in various forms: in some cases as “specialities” in the shape of instruments, said to be convenient and portable, for the removal of our heading; in others as strictures, not only in various parts of the genital canal, but on the whole subject. The menstruum of sterility itself is, curiously enough, an instance of a figure known in rhetoric as “oxymoron,” for, contrary to its name, it produces (if we are rightly informed) a micrococcus, which increases rapidly when once introduced, is about the size of a shilling, yellow in colour, marked on one side with the figure of St. George slaying the dragon, and on the other with the head of our most gracious Queen. Like the red blood-corpuscles, it is accompanied (in all but aristocratic circles) with a similar body, but of equal size and shape and nearly identical marking, weighing rather less, and, unlike the white blood-cells, in exactly equal proportions to the yellow body; both have a tendency to form rouleaux. In the menstruum we have mentioned, their excessive multiplication is liable to be followed (according to the powers of resistance of the patient) by rapid loss of health, both physical and moral, even though the micrococci are removed as rapidly as they are produced. Their resistance to reagents is remarkable; they are rapidly soluble only in aqua regia, though the white variety slowly forms a black sulphide. Thus much about the micrococci. We must now notice a somewhat new departure with regard to the question of sterility—a departure which, like other disturbances, has been previously seen on the other side of the Atlantic, and which has at least a claim to originality. This consists in the proposal to endeavour to cure sterility not only in sterile but in fertile women—an object to be achieved by a careful local supervision in the intervals of pregnancy, with a view to eliminating deviations from a “normal” standard, such deviations including retroversion, fissure of the cervix, patulous os, glairy discharge (i.e., the normal cervical secretion). These conditions, we are told, we “must” remove. We are not able to state how many healthy women with the above “abnormal” conditions would probably, and in our opinion rightly, decline to be treated at all (for it must be remembered that these conditions are to be searched for by

the physician, not merely discovered while investigating complaints); but we will enumerate a few of the things we “may” do. These include applications of nitric acid to the canal of the cervix, tracheloraphy, pessaries (of course), posture (not omitting the Turkish attitude of prayer), garment-suspenders, &c. What with the micrococci, the treatment that *must* and the treatment that *may* be carried out, there is reason to fear that some of the bolder female spirits will heartily wish they had been born with empty pelvises, or at least to rectify the mistake as soon as possible; and to get rid of organs which, it would seem, are to leave their unfortunate owners never free from investigation.

#### “DRUNK OR DYING.”

FROM the report of a recent inquest on a case in which the police had failed to discriminate between apoplexy and drunkenness, it appears that a medical witness remarked, “It was a mistake police officers often made; but the local police had been attending the Ambulance lectures, and, he thought, would have been able to distinguish the two.” This would seem to imply that at least one member of the profession expects more than it is reasonable to expect from the modicum of information it is possible to acquire in the course of a system of instruction which is rather well-intended than well-advised. If the teaching given by the Ambulance authorities were more modest, it would be incomparably more useful. It is not mere surplussage to talk to policemen about the special symptoms of drunkenness as distinguished from apoplexy. Even trained medical men have often great difficulty in recognising the difference between the two states, and, as we know, mistakes sometimes occur even in hospitals. The police should be instructed to treat *all* insensible or drowsy persons as though they were suffering from illness, and to send at once for medical aid. If the case prove to be one of simple drunkenness, the fee for attendance could be added to the fine imposed; if not, it would be only too gladly paid by the friends of the patient. It is inevitable that mistakes should occur if the police are permitted to attempt a diagnosis. We should be glad to hear that the whole system of instruction by “lectures” and “examinations” given under the auspices of the Ambulance Association had been revised, and that instead of the bewildering, because quasi-technical, knowledge it is now desired to inculcate a few simple principles were laid down, with sole reference to the prevention of accidents, until proper aid can be obtained. It is in no spirit of jealousy that we make these remarks. The Ambulance Association might do excellent work, but it has overstepped its province and is ill-advised. This is manifest from the questions set in the “examination papers.”

#### COUNTRY RESIDENCE FOR OUR CITY POOR.

THERE is no agency more widely applicable in the treatment of disease among the poor than change of air or country residence. Often the physician feels the immense advantage to the convalescent which, in all likelihood, would follow a month's sojourn at the seaside, or in some quiet corner where pure air could be inhaled and good milk freely drunk. It appears akin to sarcasm, however, to advise the father or mother who earns but a few shillings a week to leave their charge and go health-seeking, while the others may starve; and at present it is only the few fortunate recipients of the charitable card who can obtain that relaxation so much needed. Now that the population of the towns is so aggregated and the rural districts so thinly occupied, difficulty is found in obtaining labourers for the ingathering of the crops; and this has been specially felt during the past few years, when the harvests have been protracted by unsuitable weather. High wages were vainly offered, and

severe losses were occasioned through the scarcity of labour. Without doubt many thousands of our city population could find employment of a remunerative kind, cheap lodgings, and wholesome food during the approaching harvest, and a month's labour of this kind would give a return in the shape of robust health, enough to carry their fragile bodies through the hardships of the winter. When mills are running short time and complaints of dull trade are heard on every side, advantage may, without indirect loss, be taken of this means of obtaining the best results of country residence now open only to the rich. Employers might allow relays of their workmen to enjoy these advantages for suitable periods of time, and farmers would be much relieved by such a supply of labour, perhaps at wages less than regular farm labourers can claim.

#### CARBOLISED NERVE LIGATURES.

NERVES were used as ligatures in experiments made at the early part of the present century, but were never introduced into practice. In the active search for the best material for ligatures that is now being prosecuted, the applicability of nerves has again been put to the test. Dr. John A. Wyeth of New York records in the Archives of Medicine for June a case of malignant tumour of the upper jaw, which spread into the adjacent sinuses and cavities and was accompanied by dangerous hæmorrhage, in which he ligatured the common carotid artery on the same side, using the sciatic nerve of a calf. The nerve was the size of the median or ulnar nerve in the arm, and was soaked in an aqueous solution of carbolic acid, 5 per cent., for twenty-four hours before use. The nerve thus prepared was "very strong by virtue of its neurilemma, and soft and cushioned, since its cylinders of neurilemma were filled with the white substance of Schwann." To prevent any possibility of slipping the two ends of the knot were tied together with catgut, and the ends were then cut off short. The woman recovered from the operation and lived for seven months. The carotid artery was found to be "completely occluded and its continuity unbroken. There was a depressed ring, scarcely appreciable, at the point where the ligature had constricted it," and the ligature had completely disappeared. Dr. Wyeth has also used a nerve ligature to tie the carotids of a horse and of a large greyhound, and has examined the parts after five weeks. The carotid of the dog was occluded. "The ligature had slipped from its place on the horse's artery and it was permeable. There was a roughened surface at the point of deligation, due to proliferation of the endothelia." As the animal was plunging violently at the time of the operation, Dr. Wyeth is doubtful if the operation was satisfactorily performed. Both ligatures were completely absorbed.

#### THE DUKE OF YORK'S SCHOOL.

THE revelations of grievous mismanagement in the Greenwich Hospital School, to which we called attention in our issue of the 17th ult., naturally suggest the question whether such a state of things exists also in the analogous army institution—the Royal Military Asylum at Chelsea. We regret to say, from inquiries we have made, that there are strong grounds for believing that a similar ill-advised course of money-saving has been adopted there of late years, and with corresponding results in bringing the health and physical condition of the boys to a low ebb. We understand that a committee has been carrying on an investigation into the system adopted at the asylum and its effects, educationally and physically, on the boys. We shall look with much interest for its report, which, we presume, will be presented to Parliament, as was the case with that of the Greenwich Committee.

#### MONTROSE ROYAL LUNATIC ASYLUM, INFIRMARY, AND DISPENSARY.

THE centenary of the opening of this institution was celebrated last week. It would appear that this was the first establishment provided for the care of the insane in Scotland, and originated in the thoughtful care of Mr. Carnegie of Charlton, in the neighbourhood. In 1839 the Infirmary was separated from the Asylum, and in 1859 the splendid building at Sunnyside—costing up till now £50,000—was provided for the insane patients. Dr. W. A. F. Browne (late Commissioner in Lunacy) was the first resident medical superintendent, was appointed in 1834, and happily still survives. It was not till 1800 that the next asylum was opened at Aberdeen, and before 1839 other five had been added. Many improvements have been carried out since Dr. Howden was appointed superintendent twenty-five years ago, and the addition of a wing four storeys in height is just now finished. The sanitary arrangements are very complete. Each watercloset is directly connected with the main drain outside the building; this is at all points disconnected from the house and thoroughly ventilated along its course, and is open at its highest and lowest points, so that a current of air may pass through it without impediment, and the sewage is at once conveyed by gravitation to a farm of 200 acres, and distributed in a perfectly harmless and almost odourless manner. Dr. Mitchell, one of the Commissioners in Lunacy, states that "in no Scotch asylum certainly, and probably in no asylum in the empire," are the sanitary arrangements so complete. There are at present about 360 patients in the house, and accommodation is now provided for a much larger number. At the commemoration gathering the greatest satisfaction on the part of the directors was expressed towards Dr. Howden, who unfortunately was confined to his bedroom from illness.

#### THE BEARING OF DRUNKENNESS IN CLUB PATIENTS.

WHEN drunkenness in an Oddfellow leads to sickness he is not entitled to the benefit of the club during the said sickness. The rule is that—"any member incapable of following his employment by any immoral or disorderly conduct, by fighting, or by accident or illness arising from intoxication, or continued excessive drinking, shall not be entitled to any sick pay." The rule is a most proper one. And an equally proper inference from it would seem to be that a member should have no claim on the medical attendant of the club for accident or disease so disgracefully incurred. The question has often been raised. It has been lately raised most properly before J. Stephen, Esq., County Court Judge, Holbeach, by Mr. A. H. Haines, in an action for £22 18s. for attendance upon a club member for delirium tremens and other disorders caused by drunkenness. The man at various times seemed to recognise that attendance on his ailments was a private affair between Mr. Haines and himself and had paid various bills on that view. The jury, we are glad to say, gave prompt judgment for the plaintiff for the whole amount, in spite, we regret to say, of some hesitation on the part of the judge. The judge did not see that the medical officer of the club was exempted from the duty of attending a member because of the rule quoted above. He thought the rule not at all explicit enough for this purpose. But he regarded the defendant's conduct in paying bills to Mr. Haines from time to time as capable of being construed into a kind of implied contract between himself and Mr. Haines. The sooner Oddfellows and other benefit societies make their rule complete the better. It is absurd and unjust to bind the medical officer to attend drunken members. Benefit societies have an enormous power for good in marking drunkenness as an offence against

societies and the working class generally. And they owe it to their medical officers to protect them in this matter. The profession is indebted to Mr. Haines for fighting this question very well before judge and jury.

### GUNSHOT WOUND OF BRAIN.

A CASE of survival after a severe gunshot injury of the brain has recently occurred at Torquay. On June 14th a young gentleman, nineteen years of age, was found lying on the ground near Torquay, with a pistol-wound in the head. He was taken to the Torbay Hospital, and from information kindly afforded us we are able to state the nature of his injuries. There was a wound in the right temporal region, perforating the skull and the dura mater, and permitting the escape of brain matter. There was also extensive comminution of bone in the left parietal region from internal impact of the bullet, but here there was no external wound. When found the lad was conscious, and all symptoms of shock and concussion soon passed off. On the fifth day left facial and lingual paralysis was noticed; no other paralysis or any alteration in sensibility has since developed itself. The temperature has been within the normal range except a single rise to 102° on the third day, and the pulse has been regular throughout, only ranging from 60 to 68. The lad eats and drinks well, and his intellectual faculties are good. The wound is granulating, and up to the 5th inst. no fresh symptom had arisen. The bullet is conical, one-third of an inch in diameter, and it remains lodged in the cranium. According to Dr. Ferrier's experiments, the injury to the convolutions is localised in and near the ascending and middle frontal convolutions. This case has been mentioned in the lay press, where it has been erroneously stated that a considerable part of the frontal bone with brain matter attached had been shot away, and great surprise has been expressed at the boy's living after such an injury. The case is very interesting and remarkable, but by no means unique. Larrey drew attention to the fact that bullets may remain encysted in the brain for years without producing symptoms. In the surgical history of the American war many cases of recovery—some partial, some complete—after perforation of the brain by bullets, and after comminuted fractures with destruction of brain-matter, are recorded. In the Franco-German war other similar experiences were met with, and Dr. Gilbert Smith has related the case of a man who recovered from a sabre-cut received in the first Carlist war. The wound was followed by hernia of the brain, and the man was seen alive and well several years afterwards, with a large cavity within the skull, and an opening in the bone. His faculties were unimpaired, as shown by the fact that he was engaged in his business of a photographer. It is a well-known fact that injuries to the anterior part of the brain are less serious than similar injuries inflicted further back.

### DUNDEE ROYAL INFIRMARY.

A PUBLIC meeting, called by the directors, and largely attended, was held a few days ago, when the feeling was unanimous against the provision of a separate hospital for children. It was, however, agreed that the establishment of a children's ward is advisable, and a committee was appointed to secure funds. It might have been well had such a course been pursued in the University towns in Scotland, as already in Edinburgh and Aberdeen independent institutions have been established which are attended by but a small proportion of the students. It is bad enough that many men should be licensed with an imperfect knowledge of some special diseases, but it would be intolerable to have children's diseases considered as a specialty either by teachers or students.

### DRINKING-WATER IN INDIA.

WE have received a copy of a lecture delivered in Madras on April 1st, 1882, by Dr. M. C. Furnell, and published by the National Indian Association, on "Water and its Effects on Public Health." The object of the lecture was to draw the attention of the public to the widespread disgusting pollution of the tanks from which the drinking-water of the greater part of the population of India is obtained, and to enlist their co-operation in the adoption and practical working of measures to get rid of this fruitful source of disease. In the lecture Dr. Furnell related many instances which had come under his personal observation, in the course of his inspections as Sanitary Commissioner, of the manner in which the water is contaminated, and all regulations for its protection are systematically disregarded. He showed the good effects of obtaining a supply of wholesome water and protecting it from pollution in the instances of Guntur and Madras, the former of which has been free from cholera since 1868, and the latter has enjoyed a marked exemption from that disease since the town was supplied with water from the Red Hills. Dr. Furnell suggests the adoption and strict enforcement of a regulation that "in all municipalities, villages, and communities, certain tanks and wells shall be set aside *strictly* for drinking only. That bodies, clothes, animals, &c., shall not be washed there, but in certain other tanks." We wish him every success in this commendable endeavour to teach the people in Madras the value of a pure water-supply in preventing the spread of disease, and the important aid which individually can be given in carrying out well-conceived regulations to effect so desirable an object.

### EXTENSION OF THE CRUELTY TO ANIMALS ACTS.

WE are glad to see that a short Bill—which there ought to be no difficulty in passing—has been brought in by Mr. Anderson, Mr. Samuel Morley, Mr. Jacob Bright, Mr. Passmore Edwards, and Mr. Buchanan, to place pigeon-shooting from traps or any similar contrivance under the ban of the Acts now in force "for the prevention of cruelty to animals." Possibly it might have complicated matters if the hunting of tame deer had been included under the same provision, but we heartily wish it could have been. Neither pigeon-shooting nor tame-deer hunting is "sport," in any true sense of the term, and they ought to have been placed in the same category with other forms of cruelty. It would tend greatly to improve the public taste and to clear the public conscience if these two seemingly small but really important blots on our humanity could be effaced.

### PAY PATIENTS AT THE NORFOLK AND NORWICH HOSPITAL.

AT a meeting of the Norfolk and Norwich Medical and Chirurgical Society, held in Norwich on Tuesday last, Mr. Horace Turner moved the following resolution: "That, in the opinion of this meeting, the admission of pay patients into the Norfolk and Norwich Hospital, to be under the care of members of the staff only, who may be allowed to charge fees for their attendance, would be most unjust in its operation towards, and injurious to the interests of, medical practitioners in both county and city." There was a full attendance of members and an animated discussion took place. Ultimately the motion was carried by an overwhelming majority, the minority consisting of one member of the staff of the hospital. We are glad to learn that although five members of the staff were present, only one was found to oppose the motion, while one supported it, and three abstained from voting. After such an expression of opinion, it is to be hoped that even the one

who voted in the minority will be convinced that his position is untenable, and that the whole staff will withdraw from what would have been an utterly false position. The whole question of the admission of pay patients to charitable institutions is beset with objections and difficulties, but that the acting staff of a hospital should be allowed to take fees from such patients is a notion which ought not to be entertained.

### THE SEGMENTAL NATURE OF THE SPINAL CORD.

THE spinal cord may be regarded as composed of a series of segments, indicated by the pairs of spinal nerves. According to Lüdertitz this view of its structure is morphologically correct. The spinal cord of the ringed snake shows a slight rounded swelling opposite each pair of nerves, which lies above the junction of the respective vertebrae, and constantly corresponds in height to the middle of a segment. The enlargement is due chiefly to that of the grey substance, but partly also to that of the white and to an increased size of the so-called lateral group of cells. The demarcation between the segments cannot be exactly determined, but they are longer in the middle of the cord and shorter towards the extremities, especially towards the basal portion. Similar segmental swellings are to be discerned in the spinal cord of the rabbit, even on naked-eye examination. Careful microscopical measurements of the areas of the several constituents of the cord in transverse section show an analogy between these elemental segments and the swellings of the cervical and lumbar enlargements. The middle part of each segment, for instance, bears a similar relation to the extremities of each segment when the area of the constituent columns is compared. The increase in size at the middle of each segmental swelling is greater in the transverse than in the antero-posterior diameter. The grey substance is enlarged in all directions, but especially in width. The spinal cord of man, however, presents no segmental swellings, and its elements can only be recognised by the intervals between the series of nerve-roots which arise from it. These intervals are larger between the posterior roots than between the anterior, and they are the greater the longer are the segments, being greatest in the middle and lower dorsal regions.

### FLOWERS FOR HOSPITALS.

THERE are few more delicate ways in which children can be brought under some sense of interest in the sick than by the device of a flower service for them in the various churches. We have already noticed a very successful effort of this kind by Canon Carpenter. We are glad to record a similar one by the Rev. Cecil Moore, St. John's Church, Paddington. The chancel space was one mass of flowers and fruit, and the communion table was covered by very beautiful flowers, nectarines, grapes, and strawberries. Some special cases of sickness in the district were not forgotten in the distribution, but the chief recipients were the patients in the various hospitals.

### THE SALVATION ARMY.

WE will not withhold our good wishes from the Salvation Army, in the matter of its main object—"War," as "the General" puts it—"against drink, sin, and the devil." In our own way we are always waging a similar war. Our methods vary. The method of General Booth may lead to great and rapid disappointment if it depends too much on excitement and sensational appeals to the feelings. But we admit the urgent necessity of some adequate means of rousing men from vice and sin. The organised churches are too strait-laced and minister too exclusively to the good or those who think themselves so. "They that are whole need not a

physician." If General Booth can abate drunkenness, increase purity, and put the churches on their mettle as moral and spiritual forces, he will gain the praise of "The Master," and the thanks of all good men.

### COLLEGE OF PHYSICIANS IN IRELAND.

A MEETING of the Fellows will be held this week to make two appointments—viz., that of the King's Professorship of the Practice of Medicine, vacant by the resignation of Dr. William Moore, and the King's Professorship of Midwifery, vacant by the death of Sir E. B. Sinclair. For the first there are two candidates, Dr. John Magee Finny and Dr. J. W. Moore; and for the second no less than six gentlemen have declared their intention of competing. They are Drs. John Rutherford Kirkpatrick, John Augustus Byrne, J. M. Madden, Wm. Cox Neville, R. D. Purefoy, and W. J. Smyly. Of these, but one is a Fellow of the College of Physicians, while two are Fellows of the Royal College of Surgeons in Ireland.

### SIR ERASMUS WILSON.

A FEW days since Sir W. Jenner, Dr. Wilson Fox, and Dr. R. Liveing held a consultation respecting Sir Erasmus Wilson's health. They decided that he should pass the summer months at Westgate-on-Sea.

### PERSONATION AT MEDICAL EXAMINATIONS.

IT is not without reason that Mr. Macnamara directed the attention of the Council to the risk of personation at medical examinations. A case has just been heard in Dublin, before Mr. J. A. Curran, Q.C., in which a student of that city was summoned on a charge of attempting to induce a gentleman, Dr. Norris, to personate him at a Dublin examination, and offering him in the first instance £150 and afterwards £100. Dr. Norris immediately communicated with the police; hence this action. The student did not appear, but the Court issued a warrant for his arrest.

### MR. THOMAS MADDEN STONE.

ON Midsummer-day last Mr. Thomas Madden Stone completed a term of fifty years in the service of the Royal College of Surgeons of England. In 1832 he was appointed assistant librarian, and in 1853 clerk, to the College. Many generations of practitioners recall with pleasure Mr. Stone's urbanity at the registrations and examinations of the College. His courtesy and his activity alike are still unabated. On Thursday last he took part at the College elections, and "made a tally" of the votes as accurately and expeditiously as of yore.

### METROPOLITAN HOSPITAL SUNDAY FUND.

THE Fund now exceeds last year's by some £400 or £500. The total amount from Hebrew congregations is £979 0s. 6d., almost exactly equal to their total of last year. We may now fairly expect the contributions for 1882 to reach at least £34,000.

THE College of Physicians and Surgeons of Chicago, U.S.A., has been incorporated. The building forming its local habitation is expected to be completed by September next. The list of the Faculty is published in the *Western Medical Reporter*.

DR. PATRICK HERON WATSON has been appointed one of the Surgeons in Ordinary to the Queen in Scotland, in the room of Professor Spence, deceased.

At a meeting of the Executive Committee of the Darwin Memorial Fund, held on June 30th at the Royal Society's rooms, Burlington House, it was announced that the total subscriptions already promised or received amounted to £2487 13s. It was decided that the memorial should take the form of a marble statue; and a sub-committee was appointed to make the necessary arrangements. It was agreed to ask the Trustees of the British Museum for permission to place the statue in the large hall of the British Museum (Natural History), South Kensington. The following gentlemen form the sub-committee:—Mr. W. Bowman, Sir J. D. Hooker, Professor Huxley, Mr. C. T. Newton, and Sir F. Pollock, with the Chairman, Mr. W. Spottiswoode (President, Royal Society), the Treasurer, Mr. John Evans (Treasurer, Royal Society), and the Hon. Secretaries, Professor Bonney and Mr. P. Edward Dove.

At the 101st annual meeting of the Massachusetts Medical Society, held on June 13th, a debate arose with regard to the admission of women to the Society. A motion in favour of altering the by-laws so as to admit them was met by an amendment referring the subject to the Council, and declaring that it was expedient that women should be admitted on the same terms as men. The amendment was carried; but when the matter came before the Council, that body decided by 65 to 36 votes to postpone the whole matter indefinitely.

At the recent meeting of the American Medical Association, held at St. Paul, Minn., in the first week in June, steps were taken to promote the publication of a weekly medical journal in lieu of the annual volume of Transactions hitherto issued. A board of trustees (consisting of Dr. Sayre of New York, Dr. Toner of Columbia District, Dr. Foster Pratt of Michigan, Dr. R. J. Dunglison of Pennsylvania, Dr. R. Battey of Georgia, Dr. W. J. Peck of Iowa, and Dr. H. O. Marcy of Massachusetts) was nominated to further this object.

PROFESSOR HERMAN KNAPP, M.D., has accepted the chair of Ophthalmology in the University of the City of New York, made vacant by the resignation of Professor D. B. St. John Roosa.

THE vacancy in the list of honorary surgeons to the Viceroy, caused by the lamented death of Surgeon-Major R. W. Cunningham, M.D., has been filled up by the appointment of Surgeon-Major G. C. Chesnaye, of the 4th Goorkhas.

THE General Medical Council is still sitting at the time of our going to press, and the session seems likely to continue for a day or two longer.

SMALL-POX having broken out in Cape Town, a large quantity of vaccine lymph has been forwarded to the colony at the request of the Government.

THE PRINCESS ALICE MEMORIAL HOSPITAL.—On Wednesday Princess Christian laid the foundation stone of the Princess Alice Memorial Hospital, at Eastbourne. The late Princess Alice, it will be remembered, resided at Eastbourne with her family several weeks in the autumn prior to her death, and on her decease it was resolved at a town meeting to give expression to the respect in which she was held by erecting what should be called the Princess Alice Memorial Hospital. An acre of ground, within a short distance of and to the west of the railway station, was given as a site by Mr. C. Davies Gilbert, and subscriptions to the amount of £3300 having been obtained, a contract to erect the building for £4547 was entered into.

## BRIGHTON SEWERAGE.

THE Report of Sir Joseph Bazalgette on the Sewerage of Brighton reached us last week, after THE LANCET was issued, or we should gladly have printed it. We now print it *in extenso*. The suggestions made by the eminent sanitary engineer, to whose judgment the Corporation has appealed, afford the most complete justification of all that we have urged on the subject. Indeed, the new works recommended and the alterations required exceed in extent and costliness anything we had contemplated. It is not our purpose, on the present occasion, to enter into a discussion of the means by which Sir Joseph Bazalgette hopes to remedy the defects he has discovered. Doubtless some of them are valuable, while to others we should be inclined to demur as either insufficient or inappropriate. Suffice it to say that the number and expense of the measures suggested to meet what he calls "minor exceptions" are alike startling. The authorities of Brighton are to be congratulated on the decision at which they have promptly arrived to carry out the extensive series of works recommended by their engineer, without either delay or parsimony.

If the advice of Sir Joseph Bazalgette was requested before we called attention to the subject, that in itself would be evidence that a strong misgiving existed as to the actual state of matters. If, on the other hand, it is only since the appearance of our articles the Corporation has recognised the need of a scrutiny, and entrusted the task to an authority of its own selection, the people of Brighton should be thankful for the assistance we have been able to give them, and we shall have cause for self-congratulation that we raised the warning cry in the interests of public health. In any case, the sewerage of Brighton will now be thoroughly overhauled, and we earnestly hope that by some measures of reform and reconstruction—whatever they may be—the insanitary condition to which we have felt it necessary to call attention will be finally changed.

## BRIGHTON SEWERAGE.

Report of Sir Joseph Bazalgette, C.B., C.E.

"Spring-gardens, London, S.W., June 27th, 1882.

GENTLEMEN,—In accordance with the instructions contained in the Town Clerk's letter of the 3rd ult., requesting me to advise the Town Council with reference to the flushing and ventilation of the public sewers in Brighton, I have examined the condition of the sewerage system of the town, more especially with reference to the ventilation and cleansing of the sewers. But before making specific recommendations on the subject more immediately referred to me, it may be well to take a brief retrospect of the results of some of the methods which have from time to time been suggested and tried for the better ventilation of the sewers of towns.

The removal or treatment of the gases resulting from decomposition in sewers, in an offensive manner, is a subject which during the last half century has received much consideration. When in 1850 I was conducting experiments on the ventilation of the sewers of London, I had the advantage of consulting with that eminent chemist, Professor Faraday, who had previously given much attention to the subject, and who, in his evidence before a Parliamentary Committee as early as 1834, had expressed the opinion that it was beset with great difficulties. Subsequently I visited some of the mines in the north of England and in Wales, in order to see how far any of the modes adopted for their ventilation could be applied to the better ventilation of sewers, and I became acquainted with most of the suggestions which have been

made for otherwise dealing with the gases generated in sewers.

In 1858 a Committee of the House of Commons, consisting of Lord Palmerston, Lord John Russell, Lord John Manners, Sir Benjamin Hall, Mr. Robert Stephenson, and Mr. Tite, directed me to make experiments on the effect produced by extracting and burning the gases of sewers by means of furnaces.

Those experiments were conducted with the furnace in the clock tower of the Houses of Parliament, and I subsequently gave evidence before that Committee, to the effect that in the immediate neighbourhood of the furnace the indraught was found to be very strong, but that, whilst the supply of air was drawn with great force from the sewer inlets close to the furnace, the air current produced in the sewers at a short distance from the furnace was scarcely perceptible.

The Committee of the House of Commons reported that although such a process might be advantageous to sewers within a short distance of the furnace, it could not be successfully applied to any wide range of sewers on account of the number of openings which unavoidably communicate with them, the nearest of which to the furnace would supply it with atmospheric air, whilst the gases in the further part of the sewers and house drains would remain unaffected by its action.

In a mine there is but one downcast and one upcast shaft, and all the air brought into the mine at the downcast shaft can be directed and conducted at will, and discharged at the upcast shaft after it has passed through the whole length of the various galleries; whereas, in an ordinary system of town sewers, provided with inlets for the admission of water at every house drain, gully, and branch sewer connexion, the beneficial effect of furnaces, fans, or air pumps, becomes limited to a comparatively small area. But, wherever furnaces exist in the neighbourhood of sewers, it is, nevertheless, desirable to connect them with the sewers. In long lines of intercepting and outfall sewers, which have no branch connexions or openings along their route, furnaces have been, and may be used with the same beneficial results as in mines.

In 1866 Dr. Miller, F.R.S., and I conducted a series of careful experiments on the effect of ventilating sewers through charcoal, which extended over a period of twelve months, and embraced a large drainage area. The sewers were cut off from all other means of ventilation, except through charcoal trays of various forms fixed in the ventilators. We found that whilst dry charcoal is an efficient means of deodorising and disinfecting sewage gases its introduction into the ventilators produced a sensible retardation of the current of air in the sewers, and the carbonic acid in them was increased, on an average of our experiments, from '106 to '132 per cent., and the mean temperature in the sewers was thereby raised from 50.8° to 56.2°. The beneficial effect of charcoal is, moreover, considerably reduced by moisture, and it therefore requires renewal at no very distant periods, varying according to the state of the atmosphere. Charcoal may be introduced with advantage into such ventilators as are the cause of any special annoyance, but as they retard the current of air their number and area would, if generally adopted, have to be increased to an extent which is for many reasons undesirable.

Shafts connected with the sewers, and carried through lamp-posts in the streets, or to the tops of adjoining buildings, away from the chimneys and upper windows, might in many cases be so constructed as to ventilate the sewers efficiently, provided they were sufficient in number and in the area of their openings. But there is frequently much difficulty in obtaining the necessary consent for ventilators up the sides of houses on account of their having to be placed on private property.

The use of sulphurous acid and chlorine gas placed in ventilating shafts, and various other chemical or mechanical antidotes, have been attended with more or less beneficial results, and most of them may, under favourable circumstances, be applied in particular places with advantage; but all these modes of treatment require such constant attention and frequent renewal that they thus become liable to failure.

In order to prevent the evolution of noxious gases from sewage the great object to be attained is its dilution and rapid removal, before decomposition has set in, by a copious supply of water, through sewers having sufficient falls to prevent the accumulation of deposits in them. Where these

conditions cannot otherwise be sufficiently secured the sewers should be kept clean by periodical flushing.

Road detritus, if allowed to enter and deposit in the sewers, will accumulate and precipitate with it much of the sewage which otherwise would not deposit. The efficient scavenging of the surface of the roads, and the interception of the detritus washed off them during heavy rains by properly formed catchpits, are therefore essential to the maintenance of clean sewers. Macadamised, chalk, or gravel roads, especially those having steep inclinations, require particular attention in these respects.

In 1878 there were in the metropolis 1700 miles of roads, of which about 1300 were macadam or gravel, and from the surface of the whole were removed in one year over 600,000 cubic yards of detritus, at a cost of about 1s. per yard, whilst about 100,000 yards were removed from catchpits under the gullies, at a cost of 2s. 6d. per yard, and 20,000 cubic yards were taken from the sewers at a cost of about 25s. per yard. Thus it will be seen that effective scavenging and the construction of proper catchpits are economical as well as being advantageous to the condition of the sewers.

There are few who will not now recognise that the removal of the refuse of large towns by water is so vastly superior to any other known method as to have caused it to be an essential in these days of civilisation and refinement. But the underground carriers must be freely ventilated, or the gases generated in them will escape into the houses, where, being shut up and but slightly diluted with atmospheric air, they are inhaled day and night, and become injurious to health and dangerous. It will be found upon close investigation that in the great majority of cases where persons have suffered from the effect of sewer gases the mischief has arisen from defective house drainage and not from the public sewers. Every house drain should be formed of stoneware pipes laid with sufficient fall to prevent the accumulation of deposit, and ventilated from its upper end to the roof of the house; but very few are so ventilated.

The gases escaping from efficient sewers ventilated on to the surface of the roads may, nevertheless, in certain states of the atmosphere be offensive in the immediate neighbourhood of such ventilators, and although no universal system of ventilation has yet been discovered which can be always applied without any inconvenience, some satisfactory mode may in every case be selected according to the varied conditions of the localities to which it has to be applied. Attention to the foregoing principles of construction and maintenance of the sewers will very materially promote their ventilation without offence or injury.

I have carefully inspected the main intercepting sewer of Brighton, which was constructed by Sir J. Hawkshaw in 1871-4. It commences at the western end of Hove, where its invert is about 1 ft. 6 in. above high water spring tides, and it is carried under the main road facing the sea to Portobello, where its outfall is four miles east of Kemp Town, and its invert is at the level of low water spring tides. From the Steine to the outfall it is 7 ft. in diameter, and it has an average fall of 3 ft. in a mile, and this gives a mean velocity of flow of about 1½ miles per hour when running half full. But in dry weather the rising tide closes the outfall for thirteen hours out of twenty-four, and thus the lower portion of the sewer becomes a reservoir, and stores the sewage until the tide has again fallen below its level.

From the observations recently made and furnished to me by Mr. Lockwood, it appears that the ordinary dry weather flow of sewage rises during the time the outfall is closed to a maximum height of three to four feet above the sewer invert at the Roedean furnace, and it reaches the maximum there at about three hours after high water; the tide has by that time fallen below its level, and it again falls to its normal condition.

Flaps have been placed across the sewer at Roedean to prevent air from the lower end of the outfall from passing above this point. Above the flaps the sewer is connected with a lofty ventilating shaft, at the foot of which a large furnace is kept continually burning, and as there are only four small openings into the outfall between the furnace and the Steine, a continuous current of air down the sewer towards the furnace is maintained, and is very perceptible at the Steine. This ventilation at the time of my visit was quite satisfactory. The flow in this sewer is sufficient to remove all deposit, excepting a few inches in depth extending for a short distance above the Portobello outfall.

In seasons of heavy rain, however, when the sewer becomes charged with storm water the furnace ventilation

is interrupted. In order therefore to relieve the intercepting sewer during heavy and continuous rain by discharging the storm waters more rapidly, I recommend that an additional storm outlet of the full size of the intercepting sewer be constructed from it into the sea opposite the Roedean furnace, the invert of the storm outlet to be level with the invert of the intercepting sewer at that point, and that it be protected and placed under command by proper tide flaps, and penstocks to be constructed in a penstock chamber. The men who attend to the furnace could also work these penstocks when required.

I further recommend the formation of additional storm outlets at the upper or Hove end of the intercepting sewer, which also would relieve it from becoming overcharged, and thus improve its condition.

It has been suggested that the Shone system, as adopted at Eastbourne, should be applied to Brighton for the more rapid removal of its sewage, thus, it is said, preventing the generation of sewage gases and contamination of the subsoil. The Shone system, as applied at Eastbourne, is simply the application of compressed air as an agent for pumping sewage from a lower to a higher level, and thus in dry weather a continuous flow at the outfall is obtained. But, as already stated, that portion of the Brighton outfall which is tide-locked is so far from Brighton, and its ventilation is so completely cut off by flaps across the sewer at Roedean, and the outfall between Kemp Town and Roedean is so effectually ventilated by the Roedean furnace, that there are no grounds for any complaint of the ventilation of this portion of the outfall sewer, and no advantage would be gained at Brighton which would justify the expenditure for pumping the sewage from it in dry weather. The Shone system would, moreover, be quite incapable of pumping the waters brought down in times of heavy rain. The air-tight pipes, which it has been said would prevent the generation of sewer gases and the contamination of the sub-soil, are introduced in the Shone system, not as substitutes for the existing sewers, but in addition to them and for forcing the sewage received from the ordinary sewers through the iron pipes to a higher level wherever pumping may be required. It would therefore be erroneous to suppose that the introduction of these additional iron pipes would prevent the generation of sewer gases or improve the ventilation or condition of the existing system of sewers. The branch sewers of Brighton have remarkably good falls, varying mostly from 1 in 50 to 1 in 150, and pumping is therefore unnecessary, and I fail to see in what manner the Shone system could be so applied as to be of any benefit to Brighton.

There are only nine sewer connexions with the main intercepting sewer and three drains from the Aquarium between the West end of Brighton and its outfall, and no other junctions up to South Avenue, Hove, excepting a storm connexion opposite Lansdowne-place, but between it and Hove-street, a distance of 2000 feet, there are eleven sewer and thirty house drain connexions. With these exceptions the house drains of Brighton and Hove are connected with the local sewers, some of which are parallel to and above the line of the intercepting sewer.

Four catchpits have been formed in the branch sewers near to their junctions with the main sewer, one at Waterloo-street, one at Western-street, one at East-street, and one in the Steine Valley branch. Also one in the main intercepting sewer opposite Fourth-avenue. If the road detritus gets into these catchpits it is liable to collect with it the sewage mud, and it will therefore be better that catchpits of sufficient size to intercept the road detritus should be formed under the gullies near the surface so as to obviate the necessity for the catchpits in the sewer, which should then be filled in. Some of the ventilators opening on to the surface of the roads should have charcoal trays fixed in them and additional ventilating openings should be formed in the neighbouring lamp posts.

For a considerable length of the sea frontage there are two parallel roads, divided by a line of iron railings, upon which the road lamps are fixed. By substituting for some of the present lamps others of an ornamental character, having tubes of not less than six inches in diameter passing through them, and connected with the adjacent sewers, and by, at the same time, fixing charcoal trays in the road ventilators, sufficient ventilation of the sewers may be secured without annoyance.

The complaints of defective ventilation have come mainly from the higher districts, and the upper ends of the sewers which mostly have rapid falls. The upper or dead ends of

these sewers should be connected with the adjoining sewers where practicable, so as to create a current through them. Thus, for instance, the ends of the sewers in Church-street, Buckingham-road, and Leopold-road, should be connected with the Dyke-road sewer, and the sewer in Queen's-place with the sewer in London-road. A pipe carried from the end of Wellington-street to Pevensey-road, would connect five dead ends, and three near the eastern end of Eastern-road and Bristol-road should be connected. Mr. Lockwood has furnished me with a list of the complaints he has received, showing the manner in which most of them have been satisfactorily dealt with. Some few of these have been removed by obtaining the consent of the owners of adjacent houses to construct ventilators from the sewers up their sides and above the roofs; but it has been found difficult to carry this out to a large extent, owing to objections raised by owners and occupiers. To accomplish this requires very careful and patient negotiation, and must be a work of time. Although I have personally inspected all these localities I do not propose to refer to individual cases in this report.

It should be made compulsory for a shaft, not less than six inches in diameter, to be carried from the house drains up the roofs of all houses to be built hereafter. It may also be arranged in some instances that in erecting new houses pipes or flues may be carried up for the ventilation of the adjoining sewer, but the upper ends of these should always be at a distance from the windows or other openings into the houses.

Some intelligent officer might be advantageously employed for a time under your surveyor in negotiating and carrying out the ventilation of the sewers, where there is at present any cause for complaint, through gas lamps, or shafts constructed in blank walls, or into furnaces or through lamps erected at "refuges" at the street crossings, or up the blank ends of houses or by other means, according to the various requirements and opportunities presented in each case. In the course of my inspection with Mr. Lockwood, we noted several cases where these suggestions could be applied with advantage. But in most of these it would be necessary that the consents of owners and occupiers of the adjoining houses should be obtained.

Mr. Lockwood informs me that the volume of the water supplied to Brighton and Hove is about 600,000 cubic feet per twenty-four hours, giving, on the average, a flow night and day through the sewers of 416 cubic feet per minute, which on a population of 132,000, is equal to 28½ gallons per head. This is but very little below the rate of the water supply of London, which is about 31 gallons per head, and the falls in the Brighton sewers are better than in London. It has been ascertained, by measurement in the sewers, that the maximum flow during the day (that being the period when it is most needed as a carrier for the removal of town refuse) varies from three times to four and a half times the minimum flow during the night. But it has been stated that during dry weather as much as 1,200,000 gallons of water per week, or at the rate of 90 tons per day, have been used for flushing those sewers which required it. This flushing has been done by filling the manholes, at the upper ends of the sewers to be flushed, with water from the mains, and, when full, letting it go through the sewers with a sudden rush. I recommend that this be continued in dry weather, more especially at the upper or dead ends of the sewers where the flow of sewage is smaller than at their lower ends, and, if properly carried out, it ought to prevent the accumulation of deposit, but I do not recommend the admission of a large volume of tidal water into the outfall sewer for the purpose of flushing.

The branch sewers generally are too small to have enabled me to enter and inspect them, but having regard to their superior inclinations and the condition of the larger sewers which I examined, and which had not such rapid falls, and from the observations and inquiries I have made, extending over several days, I am of opinion that, with some minor exceptions, to which I have already referred, and for which I have suggested various remedies, the general condition of the sewers of Brighton is satisfactory, and there are no just grounds for assuming it to be an unhealthy place; on the contrary, I believe it still deserves the high reputation it has always maintained as a desirable place of resort for those who seek the enjoyment of pure and invigorating air.

I am, Gentlemen, your obedient servant,

(Signed)

J. W. BAZALGETTE.

To the Mayor and Corporation of Brighton."

## THE WIRRAL HOSPITAL.

ON Saturday, July 1st, Lord de Tabley, R.W.G.M., of Cheshire, laid the corner stone of the new building of the Wirral Children's Hospital. The ceremony was performed with Masonic honours, and his Lordship was supported by a large gathering of the Masons of the county. This hospital, which receives patients not from Birkenhead only, but from the whole hundred of Wirral, originated in the efforts of five local gentlemen early in 1869. The first beginnings were in a very humble way, a small house (rental about £30) being occupied till the end of 1872, when the institution was removed to the building now in use, an old dwelling-house in Oxtou-road, which affords accommodation for sixteen in-patients. During the past thirteen years the hospital has done excellent work, and the demands made upon it have been yearly increasing. Thus the number of in-patients, which from 1869 to 1872 averaged 61 per annum, during the last three years has averaged considerably over 100 per annum. Lately adequate accommodation has been so pressing needed that it has been found necessary to hire a small house about fifty yards from the hospital, where are provided six additional beds.

The determination to build a new hospital was come to last year, and so prompt a response was made to the proposal that by December a sum amounting to £4250 was raised, and it was felt that a building fund of £6000 would doubtless be obtained without difficulty. Designs were accordingly invited. The design selected has a central administration with wards on either side, something in the form of an H. It is proposed to build the centre and one side only at first, and this will allow space sufficient for about forty beds. The architect is Mr. John Clarke, and the style of the building is what is termed Domestic Gothic.

## Public Health and Poor Law.

## LOCAL GOVERNMENT DEPARTMENT.

## REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Taunton (Urban).*—Dr. Alford has recently issued his reports on the sanitary condition of his two sanitary districts during last year. The population of the borough of Taunton is given as 16,611 persons, among whom the birth-rate was equal to 30.9, and the death-rate to 20.9 per 1000 during 1881. It appears that the zymotic death-rate was 3.1 per 1000, and nearly double the rate that prevailed in 1880. This excessive zymotic fatality was mainly due to the epidemic prevalence of measles in the early part of the year. An outbreak of scarlet fever occurred in the autumn; that it did not assume serious proportions, as on former occasions, is attributed by Dr. Alford to the existence of the Sanitary Hospital. The deaths from other zymotic diseases were not numerous, but included seven from whooping-cough, six from diarrhoea, and four from diphtheria. The value of the report would have been increased by the insertion of a small table containing a statistical summary for recent years; and some reference to the rate of infant mortality might have been looked for. Dr. Alford once more takes the opportunity to impress upon the sanitary authority for the borough of Taunton the urgent necessity for ventilating the sewers, no action having yet been taken upon his special report on this subject, made in November last under instructions from the Sanitary and Drainage Committee of the Town Council. Dr. Alford warns his authority that, "until this evil [want of sewer ventilation] is remedied much sickness and ill health, and many deaths which might have been averted, will inevitably occur." Another sanitary defect to which attention is directed is the filthy condition of a great number of dwellings in the town, some of which are described as hardly fit for human habitation. A house to house visitation is spoken of as absolutely necessary, as well as more frequent visits from the inspector of nuisances, as "it too often happens that filthy houses are only found out when disease has appeared and the mischief is done." There is evidently need for greater activity or a larger staff in the sanitary department of the Town Council.

Dr. Alford speaks gratefully of the improvement of the water supply, and of the town scavenging, also of the benefit derived from the sanitary hospital, to which thirty-two patients were admitted during the year, and in which only four deaths occurred.

*Taunton (Rural).*—The Rural Sanitary District of Taunton comprises an area of more than 100 square miles, on which the population in 1881 is stated to have been nearly 20,000. The birth-rate in this population was equal to 27.6, and the death-rate to 15.3 per 1000 of the population. The deaths are stated to have been below the average for the eight preceding years, but no comparative statistics are given for those eight years, which is to be regretted, as the marked difference in the age-constitution of the population of the rural district forbids any comparison with the statistics for the urban sanitary district. Speaking generally, Dr. Alford considers that the sanitary condition of the district is slowly but surely improving, but that this improvement can only be maintained by constant supervision. Several outbreaks of infectious disease are attributed to the concealment of the first cases; and in the case of a serious epidemic of scarlet fever at North Curry, the medical officer of health admits that "it was thoroughly established, and death had occurred before I heard of its existence." Some cases of disease were admitted to the Sanitary Hospital from the district during the year. The total zymotic fatality of the district included 8 deaths from scarlet fever, 7 from measles, and 4 both from enteric fever and diphtheria, and caused a death-rate of 1.4 per 1000. The proportion of infant mortality appears from the tables to have been low, but it is not specially referred to. The report, while recording sanitary work in many parts of the district, affords abundant evidence that in the matters of water-supply and nuisance disposal much remains to be done in many of the villages to meet the increasing difficulties of rural sanitation.

*Greenock.*—Dr. Wallace reports that during the five weeks ending 3rd June the annual death-rate in Greenock was equal to 24.1 per 1000, which was 1.2 above the rate for the corresponding period of 1881. The deaths from diseases of the zymotic group did not exceed 6.2 per cent. of those from all causes; they included 2 from diphtheria, and 1 each from enteric fever and scarlet fever. It is noted that during the period under review 57 cases of infectious disease were reported; of these 35 were reported by householders, 3 by the infirmary officials, 12 by the sanitary officers, and 6 by the registrars. The cases removed to the hospital during the five weeks were 13, including 5 of typhus, 3 of scarlet fever, and 2 of diphtheria; 11 cases remained in the hospital on the 3rd of June.

*Alcester District (Rural).*—Mr. G. N. Fosbrooke, medical officer of health for one of the Midland combined districts, gives in his annual report for this district some very interesting information as to the value of maintaining in a state of preparedness means for isolating infectious cases. During the past year there have been numerous disconnected outbreaks of scarlet fever, and in six of these the disease has been limited to a single family, a result which he explains has been brought about in each case by the immediate removal of the first patient attacked to the Alcester Sanatorium. It appears that during seven years as many as 372 cases of infectious disease have been admitted into his hospital, and also that a large proportion of the patients admitted have been young children, and this although the accommodation provided is admittedly plain, and was, as a matter of fact, never intended to constitute a permanent building. To its management much of this satisfactory result is attributed, and first amongst the conditions of administration which are specified as important is the circumstance that a resident nurse is maintained who always keeps the hospital in such a state of readiness for occupation that a first case of infectious disease can instantly be received from any house attacked, and thus as a rule the spread of infection is at once checked. Mr. Fosbrooke's district includes a population of a very varying character, but it is to a large extent made up of artisans and agricultural labourers, who of all others stand in most need of means of isolation when attacked with such a disease as scarlet fever. The success experienced in his district should, he says, "act as an incentive to all sanitary authorities to provide fever hospitals," a statement in which we thoroughly concur; but we would go further in advising authorities who are hesitating as to the provision of such hospitals to visit Mr. Fosbrooke's district, and learn all the details of his continued success in this matter.

*St. Asaph (Rural).*—Dr. Lloyd-Roberts' report upon the

sanitary condition of this rural sanitary authority during 1881 acquires additional interest from the recent official inspections in Denbighshire by Dr. Parsons, under the direction of the Local Government Board, with a view to the formation of a combined district. The report before us deals with a population of 15,275 persons, and, so far as may be judged from the mortality statistics, the health of the district during last year was fairly satisfactory. The gross death-rate was 18.9 per 1000; this rate is somewhat excessive if full consideration be given to the age-constitution of the population, as evidenced by a birth-rate not exceeding 28.8 per 1000. However, the proportion and rate of zymotic fatality were very low, only 4.8 per cent. of the total deaths being referred to the principal zymotic diseases, equal to a rate not exceeding 0.5 per 1000. The rate of infant mortality was also low during last year. Dr. Lloyd-Roberts appears to have published annual reports for this district since 1875, and this being the case we regret to miss from the present report a summary table of the principal statistics for the six or seven years embraced by these reports. Statistics for a single year relating to so small a population as that of St. Asaph district, standing alone, are of comparatively little value as a test of sanitary condition. In the face of the local sanitary shortcomings pointed out by Dr. Lloyd-Roberts, it is unsatisfactory to learn that "no public works have been carried out during the year." It is evident that much still needs doing in the way of sewerage and improvement of the water-supply, and, with such a report as the present in their hands, the rural sanitary authority of St. Asaph cannot plead ignorance of their urgent public health duties.

### VITAL STATISTICS.

#### HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns, 5739 births and 2936 deaths were registered during the week ending the 1st inst. The annual death-rate in these towns, which had been equal to 19.0 and 19.1 per 1000 in the two preceding weeks, declined last week to 18.1, and was lower than in any previous week of this year. The lowest rates in these towns last week were 9.5 in Wolverhampton, 12.5 in Huddersfield, 13.1 in Sunderland, 13.3 in Brighton, and 13.5 in Norwich. The rates in the other towns ranged upwards to 22.3 in Liverpool, 23.5 in Bolton, 24.4 in Manchester, and 25.1 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns were 464, and exceeded by 8 the number returned in the previous week; 135 resulted from whooping-cough, 96 from diarrhoea, 87 from measles, 74 from scarlet fever, 46 from "fever" (principally enteric), 17 from diphtheria, and 9 from small-pox. No deaths from any of these diseases were recorded last week in Norwich, while they caused the highest death-rates in Bolton and Hull. Whooping-cough was proportionally most fatal in Bolton and Bristol; measles, in Huddersfield and Plymouth; scarlet fever, in Hull and Brighton; and "fever" in Portsmouth, Bolton, and Hull. The 17 deaths from diphtheria in the twenty-eight towns included 12 in London and 2 in Liverpool. No death from small-pox was recorded in London, whereas 3 were returned in its suburban districts, 3 in Nottingham, 2 in Salford, and one each in Liverpool, Manchester, Leeds, and Hull. The number of small-pox patients in the metropolitan asylum hospitals, which had steadily declined in the nine preceding weeks from 350 to 242, further fell to 233 on Saturday last; 29 new cases of small-pox were admitted to these hospitals during last week, against 44 in each of the two previous weeks. The deaths referred to diseases of the respiratory organs in London, which had been 200 and 198 in the two previous weeks, rose to 212 last week, and exceeded the corrected weekly average by 11. The causes of 63, or 2.2 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Leicester, Bolton, Oldham, and in five other smaller towns, while the proportions of uncertified deaths were largest in Sheffield and Hull.

#### HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight large Scotch towns, which had been equal to 20.8 and 22.4 per 1000 in the two preceding weeks, declined again to 21.9 in the week ending the 1st inst.; this rate, however, exceeded by 3.8 the mean rate

last week in the twenty-eight large English towns. The deaths referred to the principal zymotic diseases in these Scotch towns were 100 last week, and showed an increase of 18 upon the number returned in the previous week; they included 32 from diarrhoea, 25 from whooping-cough, 17 from measles, 12 from "fever," 10 from diphtheria, 4 from scarlet fever, and not one from small-pox. The 32 deaths attributed to diarrhoea showed a further slight increase upon recent weekly numbers, and were 5 above the number in the corresponding week of last year; 10 occurred both in Glasgow and Dundee, and 7 in Edinburgh. The 25 fatal cases of whooping-cough also showed a further increase upon recent weekly numbers, and included 16 in Glasgow and 5 in Edinburgh. The deaths from measles, which had been 24 and 7 in the two previous weeks, rose again to 17 last week; 8 occurred in Dundee and 4 in Glasgow. The 12 deaths referred to "fever" also showed an increase, 5 being returned in Perth and 4 in Glasgow. Four of the 10 deaths from diphtheria occurred in Glasgow and 2 in Greenock. Scarlet fever caused 2 deaths in Glasgow. The deaths referred to acute diseases of the lungs in the eight towns, which had been 105 and 111 in the two preceding weeks, declined to 97 last week, and were one below the number attributed to these diseases in the corresponding week of last year.

#### HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 19.3 and 23.2 per 1000 in the two preceding weeks, declined again to 20.7 in the week ending the 1st inst. During the thirteen weeks of last quarter, however, the death-rate in the city averaged 26.8 per 1000, against but 19.5 in London and 20.5 in Edinburgh. The 138 deaths in Dublin last week showed a decline of 17 from the number in the previous week, and included 5 which were referred to diarrhoea, 4 to measles, 4 to "fever," one to diphtheria, and not one either to small-pox, scarlet fever, or whooping-cough. Thus 14 deaths resulted from these principal zymotic diseases, against 10 and 8 in the two preceding weeks; these 8 deaths were equal to an annual rate of 2.1 per 1000, against 3.0 in London and 3.1 in Edinburgh from the same diseases. The 5 deaths attributed to diarrhoea showed a further increase upon recent weekly numbers. The fatal cases of measles were also more numerous; since the beginning of the year no fewer than 551 deaths from this disease have been recorded within the city. The deaths referred to "fever" also showed an increase upon those in the previous week. The causes of 18, or more than 13 per cent., of the deaths in the week were uncertified.

### THE SERVICES.

ARMY MEDICAL DEPARTMENT.—Surgeon-Major Thomas William Wright has been granted retired pay, with the honorary rank of Brigade-Surgeon. Surgeon-Major Robert Hyde, from half-pay, to be Surgeon-Major, vice E. McGrath, promoted.

ARTILLERY VOLUNTEERS.—1st Cinque Ports: Edward Alexander White, Gent., B.A., M.D., to be Acting-Surgeon. —1st Northumberland and Sunderland: William Pope Mears, Gent., M.B., to be Acting-Surgeon.

RIFLE VOLUNTEERS.—1st Dorsetshire: Surgeon Henry Tizard, M.D., resigns his commission. —1st Flintshire and Carnarvonshire: Honorary Assistant-Surgeon Thomas Moffat, M.D., resigns his commission.

ADMIRALTY.—Fleet-Surgeon John Rorie has been placed on the Retired List from the 25th instant, with permission to assume the rank and title of Retired Deputy Inspector-General of Hospitals and Fleets in Her Majesty's Fleet. Staff-Surgeon Mark Anthony Harte has been promoted to the rank of Fleet-Surgeon in Her Majesty's Fleet, with seniority of June 15th, 1882. Fleet-Surgeon William Henry Cruice, to the *President* (additional). Staff-Surgeon Nicholas Thomas Connolly, to the *President* (additional).

THE Princess of Wales has, in sympathy with the recent opening of the new extension building of the Consumption Hospital, Brompton, signified to the Committee her willingness to become a patroness of the institution, and to allow a gallery in the new hospital to be named after her Royal Highness.

## Correspondence.

"Audi alteram partem."

THE AUDITORY METHOD OF DETECTING  
STONE IN THE BLADDER.

To the Editor of THE LANCET.

SIR,—When the microphone was first employed to intensify the note produced in sounding for stone, Mr. Foveaux, then with Messrs. Weiss and Son, suggested the plan of connecting the sound with the ear by means of an india-rubber tube, precisely in the manner just proposed by Mr. Davidson. It was tried by Sir Henry Thompson, by myself, and by one or two others, with the result now described—viz., that of rendering very slight contact with a hard body audible, although the microphone was undoubtedly more powerful in its results. There was this objection, however, to the india-rubber tube—which, by the way, need only be quite small—namely, that it interferes with the delicate handling necessary to perform those movements of light sounding which are alone of any service in searching for a small calculus or fragment. If the tube is thick or heavy, no really delicate exploration with a sound can take place, and no other mode is worth cultivating to be of any service; a fact perhaps not generally estimated at its true value. It is not with the slightest desire to detract from the credit of original idea or of ingenious resource justly due to Mr. Davidson that this is named, but to show that the plan has already been considered, and to a certain extent appreciated. Sounding for small fragments is now a thing of the past. The proceeding is required only to find the original stone, when it is small if possible, and therefore as early as its presence can be verified. The modern aspirator (*vide* THE LANCET, Jan. 7th, 1882, page 2), especially with the latest improvements, reveals, as well as removes, fragments far more certainly than any other instrument, enabling us to complete lithotomy at one sitting; after which it is very rare indeed now to have any further trouble in "searching for a last fragment."

I am, Sir, yours faithfully,

Wimpole-street, W., July, 1882.

G. BUCKSTON BROWN.

## "THE BRAINS OF CRIMINALS."

To the Editor of THE LANCET.

SIR,—In your issue of June 3rd you comment on Professor Benedikt's views on the above subject, and state that according to the *New York Medical Record* I had adduced counter facts and statistics which involve "the collapse of Professor Benedikt's attempt to furnish an anatomical basis for crime." My limited observations scarcely justify such an expression. In the brains of two murderers which I had the opportunity of examining many of the fissures were of the so-called confluent type. I then proceeded to examine the arrangement of the convolutions and sulci in my collection of brains, and found that in sixty-three hemispheres a considerable proportion of the fissures were more or less confluent. My conclusions were as follows:—

1. That a considerable proportion of the brains of hospital patients are of the confluent fissure type.
2. The chief difference to be noted between Professor Benedikt's series of criminals' brains and those which I have gone over, is the somewhat greater number of unions between typical fissures, more particularly between the fissure of Rolando and contiguous ones. Thus in his set of thirty-eight hemispheres, this fissure connected completely or incompletely with the fissure of Sylvius in twenty-four instances; in my series in only ten. In the other fissures the disproportion is not nearly so great.
3. Considering the number of brains of ordinary hospital patients which present in some degree the confluent fissure type, it would seem more reasonable not to assign as yet any special significance to it until we have fuller information about the arrangement of the convolutions in the various races, and until a much larger number of the brains of criminals of all countries have been examined.

I am, Sir, your obedient servant,

WILLIAM OSLER.

Physiological Laboratory, McGill College, Montreal.

June 12th, 1882.

## IRELAND.

(From our own Correspondent.)

In 1866 cholera was brought into Dublin by the removal to one of the city hospitals of a patient from the ship by which he arrived in port. Owing to a belief that a fresh invasion of the same dreaded disease was likely to take place in 1874, a port hospital ship was constructed and placed in the harbour during that year, with a view of intercepting contagious diseases coming from other parts. The Corporation and the North and South Dublin Boards of Guardians wish now to get rid of the expense of keeping up the floating hospital, which has cost upwards of £2000, and accommodated, it is said, only one patient since its establishment. The Dublin Sanitary Association are, however, opposed to its abolition, and believe that a means of intercepting diseases which past experience has shown are introduced from abroad, should not for the sake of a very small outlay be discontinued. They point out, further, that the object of the hospital is not to treat cases once disease has broken out, but to anticipate outbreaks of disease by preventing their introduction on shore.

The "Hudson" prizes of the Adelaide Hospital, Dublin, have this year been awarded to Mr. Austin Nathaniel Cooper (first prize) and Dr. Bradshaw. They were founded by the late Dr. Alfred Hudson, formerly one of the physicians of the hospital, for the express object of encouraging clinical and surgical study amongst advanced students. This is the second occasion these prizes have been awarded. The gentleman who obtained the first prize was also successful in carrying off the first prize in the senior class at the College of Surgeons Medical School this year, consisting of the gold medal and £10.

Dr. James Emerson Reynolds, Professor of Chemistry in the University of Dublin, will, it is announced, continue to hold the chair for another term of seven years.

A death under singular circumstances recently took place near Killarney. A young lad, seventeen years of age, had collected some rushes, and these, with a rope, he suspended on his back. Whilst proceeding over a wire fence six feet high, he got by some means entangled at the top of the paling, and, the rope being applied round his neck, he was unable to extricate himself, and remained suspended, with the rushes at the other side of the fence, until life was extinct.

Mr. W. Thomson's case of ligature of the innominate artery, to which allusion has already been made, still progresses fairly. The deeper sinuses seem to be closed, there is but little suppuration, and every prospect of a successful result to a most important operation.

The question of building a new general hospital for Belfast, to be constructed on the most approved plans and on a site more convenient than that of the Belfast Royal Hospital, has lately been brought before the public. It is alleged that the only general hospital in the town—the Belfast Royal Hospital, with 160 beds—is totally inadequate for a large and prosperous place like Belfast. It is urged that its sanitary arrangements are defective, that the situation is not a desirable one, and, in the interests of the community and the daily increasing importance of the Medical School, that steps should be taken without delay, more especially as the lease under which the Belfast Royal Hospital is held will terminate in a few years. A site in Glanavel-street has been suggested, and as there are two institutions already located there—the Ulster Eye, Ear, and Throat Hospital, and the Hospital for Diseases of the Skin—it is believed they might form wings of the new hospital.

## PARIS.

(From our Special Correspondent.)

THE last bulletin of the Academy of Medicine contains an elaborate report by M. Bouley on the case of hydrophobia which has attracted so much attention lately. The author comes to the conclusion that inasmuch as M. Denis-Dumont neglected to perform any inoculation experiments on dogs with the saliva of his patient, it is impossible to pronounce any opinion as to the nature of the maledy, or to look upon

the result as an authentic instance of the cure of hydrophobia. He thinks, however, that, considering the alarming character of the symptoms, the satisfactory termination of the case must be attributed to the administration of the pilocarpine; and even allowing that the patient was only affected with imaginary rabies, the observation is interesting, and worthy of publication amongst the memoirs of the Academy. At the meeting of the Academy yesterday afternoon, a letter containing some further details concerning this case was read. The writer, M. Chatel, of Valcougtrain, states that Grillet (the patient) had been drinking heavily from Sunday afternoon until Monday morning, and that he was then in a state of complete intoxication. It was in this condition that he suddenly started up and rushed towards the door, exclaiming, "Je suis enragé!" "No, you are not," replied one of the persons present, "only you are drunk." Once outside the house he threw himself on the ground, biting the earth, and also his hands and arms. The bystanders promptly lassoed him, intending to secure his arms, but the noose slipped round his neck, almost strangling him. Guided by the instinct of preservation, Grillet managed to free himself from the rope, and, whilst warning those who approached that he would bite them, he requested that his arms should be tied, and threw off his belt for the purpose. Being then secured, he was taken to the Hôtel Dieu at Caen and placed under the care of M. Denis-Dumont. The sequel is known to your readers. As it now stands, the case would appear to resolve itself into one of acute alcoholic delirium. The antecedents of the patient, and the peculiar form of the delirium, easily account for the error of diagnosis, but it is to be hoped that the lesson will not be lost upon the Academy, and that it will be more chary in future of the sittings it devotes to the discussion of hypothetical communications.

An interesting case of non-hereditary sporadic cretinism was related by Professor Ball. The subject, whose bust was exhibited, is a young man aged thirty, but in appearance almost an infant. He was born in Paris, and has never been exposed to any of those influences which predispose to the disease. Three of his brothers and sisters died of convulsions.

Paris, July 5th, 1882.

## ROYAL COLLEGE OF SURGEONS.

THE annual election of members of the Council took place on Thursday last. The poll was as follows:—

Mr. MARSHALL .....	165, including	5 plumpers.
Mr. H. POWER .....	144	" 3 "
Mr. CROFT .....	103	" 21 "
Mr. A. Baker .....	72	" 10 "
Mr. G. Lawson .....	67	" 9 "
Mr. Macnamara .....	48	" 8 "

Mr. Marshall and Mr. Power are therefore re-elected, and Mr. John Croft replaces Mr. Baker at the Council Board. Two hundred and forty-five Fellows, out of a total of about twelve hundred, recorded their votes.

## MEDICAL NOTES IN PARLIAMENT.

*of various orders and petitions.*

A petition against the Infectious Diseases Notification Bill was presented to the House of Commons from Birkenhead on the 30th ult., and one in favour of the measure was presented from Worcester on Monday. Brighton sent a petition on Monday for the exemption of medical men from carriage duty. Cambridge petitioned in favour of the Irish Bill for the Suppression of Union Officers. On Tuesday a petition came from Farnham against the Lunacy Districts (Scotland) Bill.

The report for 1880 of the Army Medical Department was presented.

Mr. Herbert Gladstone gave notice that he will move for leave to introduce a Bill to dispense with the provisions of the Friendly Societies Act relating to the quinquennial returns of sickness and mortality.

Mr. Round gave notice that he will move for a return showing for each county in England the number and cost of

pauper lunatics, and the expenses and debt upon county asylums.

### Vaccination.

On Monday, Mr. Dillwyn, on behalf of Mr. Hopwood, asked the President of the Local Government Board whether the Board was prepared to advise the public which of the two modes of vaccination now in use was to be preferred—viz, the matter derived from arm-to-arm, or the one with the lymph from the calf recently provided by the Department; and whether it had been shown that tubercle may be transmitted by such lymph.—Mr. Dodson said the Local Government Board, after long experience of vaccination from arm-to-arm, had every confidence in its efficiency. They had not had experience on any large scale of vaccination with lymph direct from the calf, but they believed it to be equally trustworthy. In regard to the second part of the question, the Board were not prepared to offer any advice as to the preference to be given to one form of vaccination over the other.

### Guy's Hospital.

Mr. John Talbot asked the President of the Local Government Board whether he had been able to ascertain the truth as to the small pox patient who was alleged to have gone from Guy's Hospital to the Stockwell Hospital on a public conveyance; and whether, with the view of preventing the spread of disease, he would endeavour to arrange that the authorities of the various metropolitan hospitals should have ready access to the ambulances provided by the Metropolitan Asylums Board, or by the parochial authorities, for the purpose of conveying infectious persons to the hospitals appointed for their reception.—Mr. Dodson replied that he had ascertained that the person referred to came to Guy's Hospital among the crowd of out-patients who resorted there. He was found to be suffering from small-pox, and was advised to leave the out-patient room and apply for admission to a small-pox hospital through the intervention of the parish authorities, and without exposing himself unnecessarily so as to endanger others. He went to Stockwell Hospital on a public conveyance, but that appeared to have been entirely his own act, for which the medical officer at Guy's was in no sense responsible. It was evident that the governing bodies of the London hospitals had at present much difficulty in dealing with these cases when they presented themselves, as they had no accommodation for them; and he (Mr. Dodson) had now under consideration the arrangements which should be adopted for the temporary retention of patients of this class until they could be removed, and for rendering the ambulances of the managers of the Asylums District and the parochial authorities more readily available for their removal.

On Tuesday night Mr. Hicks moved the second reading of the Beer Adulteration Bill, upon which the House was counted out, and the Bill became a "dropped order."

On Wednesday, the second reading of the Criminal Lunatics Bill was further deferred for a week. The Baths and Washhouses Acts Amendment Bill was read a third time and passed. A Bill to amend the Weights and Measures Act was brought in by Major Ross. Mr. Moore's return relating to medical officers on board emigrant ships, which was wrongly stated to have been granted last week, has been "blocked" by Viscount Folkestone.

On Thursday, Mr. Trevelyan announced that Dr. Lyons had been appointed one of the new inspectors of the Dublin convict prisons.

### Sanitary Inspection of the West-end.

Mr. Heneage asked the President of the Local Government Board whether his attention had been called to the numerous cases of typhoid, and other illnesses arising from want of proper precautions in the drainage of houses and stables in the West-end of London; and whether many well-known and experienced medical practitioners and house agents considered that the present want of proper sanitary inspection was owing to the omission of London from the Public Health Act of 1875, and that some Act for the better sanitary supervision of London was urgently required in the interests of the public health.—Mr. Dodson said he had no information respecting the prevalence of typhoid and other diseases in the West-end of London. He did not think that such a condition of things was likely to exist without the sanitary authorities reporting it. Neither these authorities nor their officers had made any

such report. The Board had no jurisdiction in the matter. He was unable to say to what extent the opinion was entertained among the well-known medical practitioners and house agents to whom the hon. member alluded, that the want of adequate sanitary inspection was due to the omission of London from the Public Health Act of 1875. At the same time, he was prepared to admit that the system of sanitary supervision in the metropolis might be placed on a better footing.

## Medical News.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen passed the Primary Examination in Anatomy and Physiology at meetings of the Board of Examiners on the 1st, 3rd, 4th, and 5th inst. :—

Francis H. Knaggs, Thomas Rhodes, Edwin Greenough, George Wilson, and Herbert W. Pilgrim, Edinburgh; Harold B. Shaw, William H. Smart, Francis M. Hale, Thomas E. Hillier, George D. Haviland, Joseph S. Hinnell, and Herbert C. W. Jones, Cambridge; Robert J. B. Howard, McGill College, Toronto; Donald F. Macpherson, New York; John St. L. Clarke, Dublin; George F. A. Da Costa and George Vincent, Aberdeen; Jas. T. Simpson, Ambrose Atkinson, Albert E. A. Pearson, Henry Waite, and George Forden, Leeds; James Lazenby, William J. Ruddock, William M. Yeoman, George R. Hall, and Joseph T. Roberts, Newcastle-on-Tyne College of Medicine; Robt. H. Rains, Joseph A. Tooner, W. Arnold, Herbert L. Williams, Carl Freese, Octavius S. Fisher, Henry A. Marsden, William J. Fern, and John Aspinall, Owens College; George C. Helps and Arthur Bullied, Bristol; Walter J. Reed, Roland J. Riley, and Ernest Maberly, Birmingham; William Evans, Edward P. P. Macloghlin, Robt. C. Owen, and John E. Nevins, Liverpool; Henry D. McCulloch, Calcutta and Glasgow; John A. Fox and George R. McIntosh Pollard, Guy's Hospital; Wm. O. Barnham, J. Calvert, and Hugh Walsham, St. Bartholomew's Hospital; W. Mackonochie and W. R. N. Maloney, St. Mary's Hospital; E. C. Hare, A. H. Fowler, A. W. Webb, and J. D. Hughes, Guy's Hospital; F. Thomas, London Hospital; P. R. Stevens, St. George's Hospital; F. C. Kempter, Westminster Hospital; William B. Yates, J. B. Mann, and J. H. White, Owens College; Arthur G. Laidler, Newcastle-on-Tyne.

**UNIVERSITY OF DUBLIN.**—At a meeting of the Senate held on the 30th ult., the following degrees were conferred :—

**BACHELOR IN SURGERY.**—William Henry Burke, James Chute, James Seymour Carson, George Fredk. Dean, Benjamin Morgan Dockrell, William Francis Law, G. H. Longhead, Chaworth Louis Nolan, William Fletcher Moore Patton, George Blakeley Russell, John N. Seymour, Travers Robert Montgomery Smith.

**LICENTIATE IN MEDICINE.**—Wm. Hamilton Allen.

**BACHELOR IN MEDICINE.**—Thomas Robert Bradshaw, William Henry Burke, Wm. Halloran Bennett, Joseph Bulfin, William Alexander Carte, James Chute, Daniel Crowe, James Seymour Carson, George Frederick Dean, Benjamin Morgan Dockrell, George Lloyd-Appjohn, G. H. Longhead, Vicars H. Fisher, Robert Howard Fienling, William Francis Law, Michael McHugh, Charles D. Moutray, Charles St. Stephen Richard Nason, Chaworth Louis Nolan, Alfred J. Rice Oxley, Henry William Peard, William Fletcher Moore Patton, George Blakeley Russell, John N. Seymour.

**DOCTOR IN MEDICINE.**—Thomas R. Bradshaw, Frederick Charles Berry, Abraham Cohen, William Lovel Hunter, Henry Malet, Charles Highatt Trench.

**MASTER IN OBSTETRICS.**—Benjamin Morgan Dockrell.

**APOTHECARIES' HALL.**—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on June 29th :—

Aslett, George Stratton, Oaklands, near Carmarthen.  
Beever, Hugh Reeve, King's College Chambers, Strand.  
Chadwick, Chas. Montague, Philpot-street, Commercial-road.  
Edwards, George Frederick, Derby.  
Fenwick, Edward Henry, Harley-street.  
Fink, George Herbert, Regent's Park College.  
Lynam, Robert Garner, the Quarry, Stoke-on-Trent.  
Penhall, William, Farnival's-inn.  
Milton, Herbert Meyrick Nelson, Richmond-terrace, Clapham.

The following gentlemen also on the same day passed the Primary Professional Examination :—

John Charles Smith, Charing-cross Hospital; Frederick Winstanley Spiller, Birmingham.

At the recent examination for the Prizes in Botany, given

annually to medical students by the Society of Apothecaries, the successful candidates were—

1st.—John Barker Smith, St. Thomas's Hospital. Gold Medal.  
2nd.—Charles Percival Crouch, St. Bartholomew's Hospital. Silver Medal and Books.

[The name "Percy" in the last list should have been "Perez."]

A COMMITTEE has been appointed to revise the rules of Addenbrooke's Hospital, Cambridge.

THE Duke of Cambridge will preside at the distribution of prizes at the London Hospital and Medical College on Tuesday the 18th inst.

A VERY successful dramatic matinee was held in Willis's Rooms on Tuesday last in aid of the funds of the Hospital for Children and Women, Waterloo-road.

THE Sultan of Turkey has given a site in Jerusalem for the purpose of erecting a hospice and ophthalmic dispensary under the auspices of the English branch of the Order of St. John.

THERE are forty-four cases of typhoid fever in the Brisbane Hospital at the present time (says the *Melbourne Argus* of May 22nd); five deaths have occurred within the last few days.

THE final tie for the Inter-Hospital Challenge Cup was played at Kennington Oval on Monday and Tuesday, the 3rd and 4th inst., between St. Bartholomew's and King's College, and was won by the latter.

**SANITARY INSTITUTE OF GREAT BRITAIN.**—At the anniversary meeting of the Institute, to be held in the theatre of the Royal Institution, Albemarle-street, on Thursday, July 13th, at 3 P.M., Edward C. Robins, F.R.S.A., F.R.I.B.A., will deliver an address on "The Work of the Sanitary Institute of Great Britain."

**METROPOLITAN SEWAGE DISCHARGE COMMISSION.** This commission met on the 30th ult., at 20, Great George-street, Westminster. There were present Lord Bramwell, F.R.S., Chairman; Sir John Coode; Professor Williamson, F.R.S.; Dr. De Chaumont, F.R.S.; Dr. Stevenson; Mr. Abernethy; and Dr. Pole, F.R.S., Secretary.

THE new infirmary which has been erected at Hope, near Eccles, for the accommodation of the sick poor of the Salford Union, will, it is expected, be opened towards the close of the present month, or early in August. Dr. Conry, the present resident medical officer at the workhouse, has been appointed as the first medical superintendent.

AT Lerwick, last week, the deaths were recorded of three very old women, at the ages of 94, 99, and 100. The centenarian was Mrs. Coutts, of Arcus, who was born in Shetland, and came to the town of Lerwick when she was only two years old. Although feeble in body of late years, her mental faculties kept wonderfully clear to the end.

ON DIT, a resident in Vevey, Switzerland, who died lately, left a will bequeathing the whole of his property, of which he was supposed to possess a large amount, to the "local hospital of the town." There being two local medical charities, the Town Hospital and the Hospice de Samaritan, the aid of the law was sought to decide between them. After considerable outlay in legal expenses, the dispute was abruptly settled by the discovery that the deceased had indulged in an unseasonable hoax, and that in fact he had not a penny to bequeath.

**THE PARKES MUSEUM.**—The first meeting of the Council of the Parkes Museum since its incorporation was held on June 29th, Captain Douglas Galton, F.R.S., in the chair, when the following officers were elected unanimously :—Treasurer: Professor Berkeley Hill, M.B. Honorary Solicitor: Mr. Basil Field. Secretary: Mr. Mark H. Judge, A.R.I.B.A. It was unanimously decided to remove the collection of articles at present housed in University College to premises more suited for the purposes of display and instruction, and a Building Committee was appointed to carry out this resolution.

**BOYLSTON MEDICAL PRIZE QUESTIONS.**—The following are the questions proposed for 1883:—1. Measles; German Measles; and their counterfeits. 2. The Differential Diagnosis of Abdominal Tumours, especially those connected with the Genito-urinary Organs. The following are the questions proposed for 1884:—1. Aseptic Agencies and Cleanliness in Wounds. To what exactly are their Good Results to be attributed? An Experimental Inquiry. 2. The alleged recent Reappearance of Intermittent Fever in New England; its History, and the Pathology of the Disease.

**PRESENTATIONS.**—On Wednesday, July 5th, a committee that had been formed among the friends of Dr. Langdon Down's patients at Normansfield, presented him with an admirably executed bust of himself in marble, by Mr. J. Sherwood Westmacott, to mark their great appreciation of the devoted care and skill their relatives had received at his hands. — Dr. J. P. Harper, late of Windsor, has, on his removal to London, been presented by his former neighbours with an ornolu casket containing a purse with 250 guineas, accompanied by an illuminated address on vellum. — Dr. Kirkwood of Largs has received a very handsome and flattering testimonial from his friends and neighbours on the occasion of his retirement from practice on account of infirm health. The presentation consisted of a silver tea and coffee service and a cheque for £1435.

## Medical Appointments.

*Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning at the latest.*

**ASHTON, C. E., M.R.C.S.,** has been appointed Resident Assistant at the Wolverhampton and Staffordshire General Hospital.

**CURRIE, O. J., M.R.C.S.,** has been appointed House-Physician to Guy's Hospital.

**DAY, T. M., M.R.C.S., L.R.C.P.,** has been appointed House-Physician to Guy's Hospital.

**GRABHAM, Dr. G. W.,** Resident Physician and Superintendent of the Asylum for Idiots, Earlswood, has been appointed Inspector of Lunatic Asylums in New Zealand.

**HEHNER, OTTO, F.I.C., F.C.S.,** has been appointed Lecturer on Practical Chemistry at Westminster Hospital Medical School, jointly with Dr. Dupré, F.R.S.

**KNIGHTS, Mr. WEST,** has been reappointed Public Analyst for the County of Cambridge.

**LOGAN, J. R., M.B., C.M.Ed.,** has been appointed Junior House-Surgeon to the Northern Hospital, Liverpool, vice Wm. Y. Orr, promoted.

**NEWMHAM, W. H. C., B.A.Cantab., M.R.C.S.,** has been appointed House-Surgeon to Guy's Hospital. Also House-Surgeon to the Evelina Hospital for Children.

**ORR, Wm. Y., M.B.Ed., M.R.C.S.,** has been appointed House-Physician to the Northern Hospital, Liverpool, vice W. R. Parker, M.B., resigned.

**PEARSE, FRED. EDW., M.D.St. And., M.R.C.P.Ed., M.R.C.S.,** has been appointed Medical Officer to the No. 1 District of the Freme Union.

**PERKS, R. H., M.R.C.S., L.R.C.P.,** has been appointed House-Surgeon to Guy's Hospital.

**PILKINGTON, H. OLDFIELD, M.R.C.S., L.S.A.Lond.,** has been re-appointed Medical Officer of Health for the Preston Urban Sanitary District.

**POCOCK, F. ERNEST, M.D.,** has been appointed Surgeon to the Kensington District of the Gas-light and Coke Company, vice T. S. Gell, M.D., resigned.

**POPE, PERCY, M.R.C.S., L.R.C.P.Ed.,** has been appointed Poor-law Medical Officer to the Weald District, Hendon Union, vice J. R. Pope, M.R.C.S., L.S.A.Lond., deceased.

**PRICE, J. A. P., B.A., M.B.Oxon., M.R.C.S.,** has been appointed House-Physician to Guy's Hospital.

**RYLEY, J. BRESFORD, M.D.,** has been appointed Consulting Physician to the Great Eastern Railway Provident Society.

**SLATER, DRUCE J., L.S.A.Lond.,** has been appointed Resident Clinical Assistant to the East London Hospital for Children and Dispensary for Women, Shadwell, E.

**STEPHENS, L. E. W., M.R.C.S., L.S.A.Lond.,** has been appointed House-Surgeon to Guy's Hospital.

**STONDS, CHARTERS J., M.S., F.R.C.S.E.,** has been appointed Surgeon to Out-patients to the Evelina Hospital for Sick Children.

**STONDS, CROFT G., M.R.C.S., L.S.A.Lond.,** has been appointed Medical Officer to the Earl Soham District of the Plumrosegate Union.

**THOMSON, T. P., M.R.C.S.,** has been appointed Assistant Medical Officer at the Workhouse of the Leeds Union, vice Richardson, resigned.

**WHITE, T. BONSER, L.R.C.P.Ed., L.R.C.S.Ed.,** has been appointed Assistant Resident Medical Officer at the Workhouse of the Bolton Union, vice Barr, resigned.

## Births, Marriages, and Deaths.

### BIRTHS.

**BATEMAN.**—On the 5th inst., at Whitechurch, Oxon., the wife of Francis Bateman, M.B.Lond., of a daughter.

**CARVER.**—On the 2nd inst., at Fairlawn, Fulham, the wife of E. J. Carver, of a son.

**CONSTABLE.**—On the 27th ult., at Kennington-park-road, S.E., the wife of J. J. C. Constable, M.D., of a daughter.

**MORSE.**—On the 23rd ult., at Prince of Wales-road, Norwich, the wife of Thomas Herbert Morse, M.R.C.S., L.R.C.P., of a daughter.

**SEDGWICK.**—On the 2nd inst., at Park-place, Upper Baker-street, the wife of Wm. Sedgwick, M.R.C.S., of a daughter.

**SMITH.**—On April 19th, at Yarra-street, Geelong, Victoria, the wife of S. Maberly Smith, of a son.

### MARRIAGES.

**CADELL-BOILEAU.**—On the 21st ult., at St. John's Church, Notting-hill, Francis Cadell, M.B., F.R.C.S.Ed., to Mary Hamilton, younger daughter of the late Major-General A. Henry E. Boileau, Bengal Engineers.

**CASKIE-MACDONALD.**—On the 29th ult., at Islington Presby-terian Church, John Boyd Caskie, M.D.Glas., to Hannah, only daughter of the late Frederick Macdonald, of Devonshire-street, W.C.

**COOPER-FLLOWER.**—On the 4th inst., at St. George's Church, Hanover-square, by the Rev. William Heath Marsh, Rector of Lammas, Norfolk (uncle of the bridegroom), Alfred Cooper, Esq., F.R.C.S., to Lady Agnes Flower, widow of the late Herbert Flower, Esq., and youngest daughter of the late Earl of Fife, K.T.

**JOHNSON-BRAND.**—On the 20th ult., at the Parish Church of Great Cornard, Suffolk, James Bovell Johnson, M.D., second son of the late Rev. W. A. Johnson, formerly Vicar of Weston, Ontario, Canada, to Elizabeth Olive, only daughter of the late Oliver Brand, Esq., of Great Cornard.

**LANGDON-D'AUTEZ.**—On the 16th ult., at the Cathedral Church of the Holy Trinity, Gibraltar, Surgeon J. S. Langdon, Army Medical Department, to Leontine, second daughter of M. G. D'Autez, of Gibraltar.

**MASSEY-MORRIS.**—On the 28th ult., at the Parish Church, Croydon, Hugh Tiley Massey, L.R.C.P., elder son of Albert Massey, M.D., of Camberwell, to Eliza Jessie, younger daughter of William Henry Morris, of South Norwood.

**MORTIMER-CROWE.**—On the 30th ult., at Trinity Church, Cleygate, Esner, John Desmond Mortimer, M.R.C.S., L.S.A.Lond., to Katie, youngest daughter of the late Alexander Crowe, Esq., of Woodcote-grove, Epsom.

### DEATHS.

**BALL.**—On the 2nd inst., at Bruce-grove, Tottenham, Tertius Ball, M.D., Retired Surgeon-Major, Army Medical Department, in his 56th year.

**BREW.**—On the 29th ult., at Pontrhydryn, near Newport, Mon., Charles Adams Brew, M.R.C.S., in his 63rd year.

**KERSWILL.**—On the 27th ult., at St. Germans, Cornwall, Robert Kerswill, M.R.C.S., aged 74.

**KNAGGS.**—On the 3rd inst., at Stratford Lodge, Folkestone, Sydney Henry Knaggs, M.R.C.S., late of New Hampton, Middlesex, in his 49th year.

**LEWIS.**—On the 25th ult., H. Harman D. Lewis, M.R.C.S., L.S.A.Lond., aged 54.

**LING.**—On the 28th ult., at Abbotsford, Torquay, Edward Clayton Ling, M.R.C.S., L.S.A.Lond., late of Darfield House, Aldeburgh, Suffolk.

**NEWINGTON.**—On the 3rd inst., Samuel Newington, M.A., M.R.C.P., of Ridgeway, Titchhurst, aged 83.

**SEARLE.**—On the 1st inst., at her residence, Donyngs Villa, Redhill, Jane Mary Searle, widow of Henry Smith Searle, F.R.C.S., formerly of Kennington, aged 76.

**VALPY.**—On the 4th inst., William Henry Valpy, M.D., second son of the Rev. F. E. J. Valpy, M.A., late Rector of Garveston, Norfolk, aged 53.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

## METEOROLOGICAL READINGS.

(Taken daily at 5.30 a.m. by Steward's Instruments.)

THE LANCET OFFICE, July 6th, 1882.

Date.	Barometer reduced to Sea Level and 32° F.	Direction of Wind.	Dry Bulb.	Wet Bulb.	Solar Radiation in Vacuum.	Max. Temp. in Shade.	Min. Temp.	Rain fall.	Remarks at 8.30 A.M.

## Notes, Short Comments, and Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*We cannot prescribe, or recommend practitioners.*

*Local papers containing reports or news-paragraphs should be marked.*

*All communications relating to the editorial business of the journal must be addressed "To the Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

## RUSTY SURGICAL INSTRUMENTS.

IN a highly sensational and unduly coloured sketch, a writer has described in *Knowledge* a case of ascites, to which some years ago he called in "the great master of British surgery, Sir Rusty Poynts," who, on being requested to tap the patient, produced for the purpose a trocar with dull point, rusty sides, and an ill-fitting cannula, and, in spite of protest, insisted on using it, pleading, "It don't signify, you know." We cannot pretend to dispute the bare facts of the case, but we may fearlessly assert that no "master of British surgery," great or small, would to-day be found who would perpetrate such a cruelty. But yet there may be quite room even now for a word of warning as to the importance not only of absolutely clean, but of very sharp-cutting instruments. Where anaesthesia is not employed the amount of pain saved by using a knife of the greatest attainable keenness is very great, while in all cases alike, attention to this particular is one of the requisites of the successful surgeon who would obtain speedy healing of wounds. It is not an unknown thing to see two or even more incisions made before skin is divided, and the result must of necessity be a partially bruised and irregular edge, the healing of which is in exactly that measure interfered with.

*M.R. should apply to Mr. Gray, Marine Secretary to the Board of Trade.*

*Ignotus.*—We should see no objection to a circular barely intimating the facts.

## "DEATH UNDER CHLOROFORM."

To the Editor of THE LANCET.

SIR,—As the junior assistant administrator of anaesthetics at St. Bartholomew's Hospital, I must take exception to the statement in your article that "the shadow of the responsibility (with regard to the death) never leaves the administrator." All I can say is that I feel no responsibility whatever. I am fully aware that the chloroform was administered with every care, and that everything was done in the endeavour to resuscitate the patient. Again, I know that there are cases, though these are happily very few, which will succumb to the chloroform, no matter how administered, and if I have had to administer the chloroform to one of these, it is not my fault, for they cannot be distinguished during life.

With regard to the question of local anaesthesia, all I can say is that if I had an epithelioma of my lip, I would not have it removed without chloroform, for if you freeze the part the pain on thawing is worse than that of the operation, and the risk of hæmorrhage is greatly increased. In conclusion, let me inform you that my name is not Mr. J. S. Streat-ham, but yours truly, J. LIONEL STRETTON, L.R.C.P. Lond., &c. St. Bartholomew's Hospital, E.C., July 1st, 1882.

## "COMMISSIONS" IN DENTISTRY.

A CORRESPONDENT sends us a remarkable letter, written by a dentist to him, offering him a commission on patients introduced, the proportion to be 15 per cent. where the fees are below £5, 20 per cent. between £5 and £20, and 25 per cent. above £20! What shall we hear of next! We would remind the author of this proposal that the General Medical Council has power to erase the name of a person from the Dentists' Register, and that the Council has awakened to some sense of its responsibilities in regard to the behaviour of registered persons.

## "RED SOCKS AND STOCKINGS."

To the Editor of THE LANCET.

SIR,—It having fallen to my lot to analyse several socks and stockings of a red colour, and being supplied with the information that they have caused great irritation to the feet and legs of the wearers, causing small pustules to arise and the skin to subsequently exfoliate, I thought it would be interesting to members of the medical profession to know that the cause of irritation is apparently the tin salt which is used as a mordant in fixing the dye. I succeeded in obtaining as much as 22.3 grains of this metal in the form of the dioxide, and as each time the articles are washed the tin salt is rendered more easily soluble, the acid excretions from the feet attack the tin oxide, thus forming an irritating fluid.

I am, Sir, yours truly,

London, July 8rd, 1882.

J. WOODLAND, F.C.S., F.L.S., &amp;c.

*Incredulous.*—1. Certain persons, owing to an idiosyncrasy, real or fancied, are unable to eat beef without suffering from indigestion. In some rarer instances mutton produces the same effect.—2. Honey from certain districts occasionally has poisonous effects, but we are not aware of its ever giving rise to the symptoms named. Some persons are unable to eat celery; it may occasion nettle rash.—3. No, very small doses may induce salivation in individuals extremely susceptible to the influence of the drug.—4. Atrophy attended with the symptoms mentioned would point to diabetes.

*A Workhouse Medical Officer.*—The question is a new one to us, and entirely a legal one. Our correspondent should raise it in the form of an objection to attend an Oddfellow as a pauper.

## "DISPLACEMENTS OF THE UTERUS."

To the Editor of THE LANCET.

SIR,—I have read your article in THE LANCET of Saturday last on Dr. Vedeler's contribution to the *Archiv für Gynäkologie* with some degree of amazement. Are we to believe that in only 15 per cent. of the whole female population is the uterus in its normal position?

I am, Sir, yours, &amp;c.,

J. WOODHOUSE.

Hertford, June 29th, 1882.

\*. In 920 healthy nulliparous women complaining of no uterine symptoms, Vedeler found the uterus in the so-called "normal position" in 8 per cent., anteverted or anteфлекed in 78.7 per cent., and retroverted or retroflexed in 13.3 per cent. The natural inference is that the term "normal position" as used at present is a misnomer, and that the uterus in health may occupy several positions, most of which are now and have been for some years regarded as displacements.—ED. L.

*Italy.*—We must refer our correspondent to a very good statement of the facts in "Medical Education and Practice," by Herbert James Hardwicke, M.D., published by Churchill, London.

*Mr. Ambrose Tomlinson.*—We are not aware that French practitioners deny the antiseptic and antifebrile properties of salicylic acid. Certainly English practitioners do not.

## CORRIGENDA.

To the Editor of THE LANCET.

SIR,—Allow me to correct the following errata in my paper on the Results of Amputations, &c., in the Glasgow Royal Infirmary. Under "primary amputations" the deaths are 99, instead of 98; mortality per cent., 32.2; and at the foot of the column under the same heading the total percentage is 32.2, instead of 37.3. Your attention to this will oblige, yours truly, M. THOMAS.

Glasgow, July 1st, 1882.

*Enquirens.*—We know of no other means than by a charge before a magistrate of using a false title under the Medical Act—i.e., a title not warranted by the nature of the diploma.

## PROVISION AGAINST SICKNESS BY MEDICAL MEN.

To the Editor of THE LANCET.

SIR,—Can any of your readers favour me with the name and address of a first-class benefit association from which, in consideration of a monthly or annual payment, a medical man would receive compensation when laid aside by sickness or disablement from accident?

I am, Sir, yours, &amp;c.,

July 5th, 1882.

PROVIDENT

## MILITIA SURGEONS.

To the Editor of THE LANCET.

SIR,—In your journal of last week, in the Parliamentary news, there appeared the following reply of Mr. Childers to a question addressed to him by Mr. O'Shaugnessy:—"In reply to my hon. and learned friend, I have to state that until 1829 militia surgeons were members of the permanent staff, and, like other officers of that staff, entitled to pensions on reduction of the force, or on retirement through age or infirmity. But no militia surgeon appointed since 1829—that is to say, during the last fifty-three years—has been entitled to a retiring allowance. Her Majesty always had the power to decide at what age militia officers should cease to serve, and in 1872 this age was fixed at sixty, although retirement was not enforced in every case. In 1881 it was decided that at sixty-five all militia surgeons must retire, this being a boon to them compared with other militia officers."

I am surprised that Mr. Childers should have fallen back upon an Act of Parliament that has no bearing on the case. If it was necessary that militia surgeons should be on the permanent staff to entitle them to pensions, how was it that ensigns, lieutenants, assistant-surgeons, or, as they were then called, surgeons, mates, and paymasters, who were never on the permanent staff, received pensions varying from 2s. 6d. to 5s. a day?

It has been shown in repeated statements addressed to Mr. Childers, and also in the public journals, that the Act of 1829 contained no such proviso, nor was it repealed at that date, as was erroneously stated by Mr. Hardy, but was in force, and continued by succeeding Acts of 10th George IV., and as lately as 31st, 32nd Vict. The words in those Acts were as follows:—"All militia surgeons who shall have served for twenty years in the militia, and who shall be retired from age or infirmities, shall be entitled to an allowance of 6s. a day." Where, then, has Mr. Childers any grounds for saying it was necessary that they should be on the permanent staff? The Act of 54 Geo. III., sec. 17, enacts that "all surgeons of militia were, after thirty years' service, or becoming unfit for duty, to be entitled to a pension of 3s. a day." This was when the pay of surgeons was only 6s. a day. If pensions were not admissible for militia surgeons, how was it as lately as 1854 Lord Panmure, then Secretary for War, issued a circular granting half-pay under certain conditions to militia surgeons? How, then, can Mr. Childers state that for the last fifty-three years militia surgeons were not entitled to pensions?

If Mr. Childers' contention be correct, and the militia surgeons are wrong in their interpretation of these Acts, why does he refuse to allow an inquiry into the case? I am aware that the opinion of three eminent counsel has been taken, and they are confident as to the correctness of the claims of the militia surgeons. I am perfectly aware that any minister if he chooses can act in an arbitrary manner and refuse to grant a hearing, but it is not equitable or in accordance with common justice, especially as any legal action cannot be taken against the Government, so that all redress is denied us, and the old saying was never more applicable than in this case, that "might overcomes right." We only ask for a committee or Royal Commission before whom our legal representative may be heard, and if we fail to prove our case, and that Mr. Childers' view and interpretation of the Acts be right, we must bow to the inevitable; or we desire that an amicable suit may be allowed to be instituted in one of the law courts, and we will rest satisfied with its decision. It is always a sign of weakness or arbitrary conduct when in private affairs one refuses to come to an amicable arrangement such as arbitration, and I do trust Mr. Childers will see the equity and justice of granting us one or other of these requests.

Mr. Childers saying it was a boon that was conferred on us by allowing militia surgeons to serve until they were sixty-five years of age is simply an absurdity, and adding insult to injury. I cannot see wherein the boon exists. Surely that cannot be called a boon which takes from a man the whole or larger portion of his income, casts him adrift at a time when he requires it most, and when he is unable to obtain any other appointment or practice.

Mr. Childers may be right when he says Her Majesty can decide when and at what age militia officers should retire, but I cannot believe Her Majesty would, if she were made acquainted with the fact, sanction turning adrift, and in some cases penniless, servants who had rendered her faithful and loyal services. The order of 1872 to which Mr. Childers refers was, as I remember, applicable only to field officers, and not a word was said about surgeons, whose appointments, under their commissions from the Lord Lieutenants, were for life, or so long as they could discharge their duties efficiently. It must be remembered that field officers, meaning thereby colonels and majors, were men of rank and position, and with ample private means, to whom the loss of twenty-seven days' training pay could have been a matter of no consideration or entailing any loss. In the case of militia surgeons—dependent in many cases on the emoluments of their appointment, the greater number of the older surgeons to whom this harsh rule applies had sacrificed their private practices to accompany their regiments when embodied, many of them serving abroad.—It certainly appears to me to be an act of the greatest cruelty to cast them adrift at sixty-five years of age without any provision whatever.

I cannot believe that any minister when he has been made acquainted with the above facts would refuse to reconsider his decision, based, as it is, on erroneous premises; and I feel confident that when the public and the House of Commons are made acquainted (as the militia surgeons must they shall be) with the facts, as set forth in our petition, and the

several documents published and distributed among the members, they will at once see the justice of recognising our claims.

I would also draw attention to the erroneous statements set forth in Mr. Bannerman's letter to the chairman of the Parliamentary Committee of the British Medical Association, wherein he states that the Act 5th Geo. IV. and all other militia Acts were only in force a year. It has been pointed out repeatedly to Mr. Childers that those Acts, though annual, were continued from year to year by the Expiring Acts Continuance Bills, and the Act of 5th Geo. IV. was only repealed in 1873, although Mr. Hardy informed a deputation that waited on him early in 1873 that this Act was repealed in 1829-30. No doubt he was erroneously informed. If I remember right, Mr. Childers (then out of office) formed one of this deputation. The other Acts under which we consider we are entitled to pension were not repealed until 1876, the year when the militia ceased virtually to be a militia, but passed under the authority of the crown, and became part and parcel of the army, when the militia surgeons accepted service under the Warrant of 1876, and joined the departmental list, they were assured that by so doing they did not forfeit any previous right or claims they possessed, one of these being the right to continue in the service for life, or so long as they could officially discharge their duties, and when retired, from age or infirmities, a right to a pension of 6s. a day. They were never informed when joining the departmental list that there was a limit of age at which they would be forced to retire, otherwise none of them would have accepted service on those conditions. In 1880 the militia regulations stated that those regiments who had medical officers attached to them would retain their services until vacancies occurred, which evidently implied that such vacancies should be the result of death or retirement from age or infirmities, as laid down by the several Acts above quoted. It was not until Jan., 1881, this arbitrary order came out compelling us to retire at sixty-five. Surely here is a clear case of breach of faith.

I am, Sir, yours, &c.,

A SURGEON MAJOR OF OVER 30 YEARS' SERVICE  
COMPELLED TO RETIRE WITHOUT COM-  
PENSATION OR PENSION.

July 1st, 1882.

To the Editor of THE LANCET.

SIR,—After serving for twenty-two years as surgeon of the Royal Wiltshire Militia, with the rank (relative) of major, simply because I did not enter into the Militia Medical Department in 1876, the War Office authorities have reduced me to the relative rank of a captain. In 1859 militia surgeons, at the time line surgeons had the relative rank of field officer conferred on them, had the same rank granted them. This was done by an order of the then Secretary for War, General Peel. In my own regiment this circular has been destroyed, and I cannot find, from inquiries I have made of a few militia surgeons, that the circular is still in existence in their regimental records.

Will you allow me to ask present or late surgeons of militia if they would kindly make inquiries, and, if successful, send either to you direct or to me a certified copy of the circular of 1859 granting field officers rank to militia surgeons?—I am, Sir, yours faithfully,

Derizes, June 28th, 1882.

### "TREATMENT OF HÆMORRHOIDS BY CRUSHING."

To the Editor of THE LANCET.

SIR,—With reference to the remarks of M. C. Chassaingue in your issue of this date, I wish to state that the method of operating to which he refers—namely, the "écraseur de Chassaingue," differs most materially from the "treatment by crushing" with my instrument, with which, however, he seems to be unacquainted. He appears to be unmindful of the fact that the "écraseur de Chassaingue" is almost, if not entirely, obsolete, at all events in England, and is now very rarely resorted to in cases of this kind; indeed, no mention is even made of it in most of the great standard works on surgery.

Under these circumstances your correspondent's concluding remark that "all that has been attempted since to modify his (M. Chassaingue's) method has led to a deterioration, never to an improvement," cannot apply to either Mr. Pollock or myself, though it appears that "the wish is father to the thought."—I am, Sir, yours truly,

Baron's-court, July 1st, 1882.

R. FITZROY BENHAM.

### SYPHON BOTTLES.

To the Editor of THE LANCET.

SIR,—Have any of your readers ever noticed symptoms of lead poisoning caused by drinking freely of soda and potash-water out of the large siphon bottles? Has anyone ever tested these waters for lead, and with what result? I think this is a most important subject, and one that public attention should be called to at this season of the year, when they are so freely consumed. Also, is it not possible that these bottles may be the means of conveying scarlet fever and other infectious diseases, as we have no idea where the bottles were a few days before they were supplied to us. Cattle-trucks are disinfected, are not human beings equally entitled to protection? I should be pleased to hear the opinions of my medical brethren.

I am, Sir, yours, &c.,

June 27th, 1882.

M.D.

## Clinical Lecture

ON A CASE OF

## EXCISION OF THE UTERUS BY ABDOMINAL SECTION.

By ANDREW CLARK, F.R.C.S., &amp;C.,

ASSISTANT-SURGEON TO THE MIDDLESEX HOSPITAL, AND LECTURER ON PRACTICAL SURGERY.

GENTLEMEN,—On the 29th of September last there was admitted into the hospital L. D—, a thin, care-worn Pole, forty-two years of age, and understanding very little English. On this account a good deal of difficulty was experienced in eliciting the particulars of her case. She came because of a rapidly increasing abdominal enlargement, and gave the following history. Had been married twenty-two years; had never been pregnant; catamenia regular from the time they commenced, the date of which she does not remember, until three years after marriage, when they ceased altogether for nine or ten years; they then recommenced, and have been quite regular ever since. She has never had an attack of menorrhagia, and can give no reason for the cessation and recommencement of the menses. She has not been a strong woman, but has never been laid up with any illness, excepting five years ago, when she was for a short time in the London Hospital for a pain in her left side, with some slight enlargement in the iliac region. The pain was cured, but the lump remained, giving her little or no trouble. She can give us no information as to her family history. With regard to her present illness, she says that in January of last year she observed her abdomen was increasing in size, and since July the increase had been more rapid; it was unattended with pain till a few weeks ago, but lately she had been subject to occasional attacks of pain in her left side. The size and weight of the abdomen rendered her life miserable and prevented her moving about; she therefore sought medical advice.

*State on admission.*—Abdomen presents a globular tumour projecting forwards, having the appearance of a uterus containing a foetus at nearly full term, rather more prominent on left side than right, and as patient lies on her back considerable bulging of left flank. The skin is stretched and tense all over the belly, but the umbilicus is normal. There is no tenderness except in the left iliac region. Tumour smooth, yielding, and elastic. No wave of fluid can be felt from one side of abdomen to the other, but there is fluctuation to be felt here and there about the tumour. The whole tumour can be moved freely in the belly, and the highest part is about two inches from the sternum. The percussion note on the front of the abdomen is uniformly dull up to the top of the tumour, the dullness extending laterally on each side rather beyond a line drawn vertically upwards from the iliac crest to the twelfth rib. Both flanks are tympanitic; the extent of the area of resonance depends on the position of the patient, but in any position the note in the extreme flanks is perfectly clear. Girth of abdomen at umbilicus thirty-four inches. Vaginal examination: Os uteri soft, and in normal position, tumour moves with uterus and appears to be part of it; uterine sound goes in a quarter of an inch beyond normal distance, giving a good deal of pain. Putting the patient on the right side and examining with the left hand the tumour appears to be isolated from the uterus.

A note made on Oct. 17th says there is no material change except that the size of the abdomen has increased to thirty-six inches and a half at the umbilicus; menses ceased to-day. Area of dullness found very variable, rarely two days alike. Patient's general appearance has improved, she is stouter and in better spirits, the condition of urine normal, and all the functions of the body properly performed. I took the case to be one of ovarian tumour more or less solid, and decided on removing it by abdominal section, particularly, as owing to the ease with which it could be moved in the abdomen, and there being no history of previous attacks of peritonitis, I believed it to be free from adhesions.

Accordingly, at 9 A.M. on October 24th, the carbolic spray No. 3072

being used, the patient was anaesthetised with a mixture of chloroform and ether, and a small incision made in the middle line to expose the tumour. A trocar was introduced and nothing but blood came out; the incision was then extended upwards above the umbilicus, and downwards to the length of nine inches. The bleeding in the abdominal wall, which was very little, was stopped by the application of the torsion-pressure forceps, and the tumour being quite free from adhesions was easily drawn out of the wound. It turned out to be a solid tumour of the uterus. There were a few small cysts in the left ovary, and the right was quite normal. I separated the ovaries and removed them after tying their pedicles with carbolised silk, and returning them; a clamp was then put upon the neck of the uterus, and it was cut off with a scalpel about an inch above. The peritoneal cavity was then carefully cleansed with warm carbolised sponges (at this point in the operation the steam spray ceased to act), and the edges of the wound brought accurately together with seven deep and two superficial silk sutures, the pedicle being fixed immediately above the pubes, which was easily done without any undue dragging; the incision was dressed with boracic charpie and carbolised gauze, and the stump covered with lint dipped in carbolised oil. The patient was then tightly bound with a flannel bandage and removed to bed, having been under anaesthesia one hour and forty minutes. I saw her about two o'clock and found her very comfortable. She had recently complained of a little pain, but obtained relief after a catheter had been passed and about three ounces of urine drawn off. A note made at 9 P.M. says the patient is perspiring freely, has vomited two ounces of clear fluid, and has had a little pain in the abdomen. Temperature 99.8°. Ordered an enema with fifteen minims of sedative solution of opium. Next morning I found patient very comfortable, having slept three hours during the night after a second enema; had vomited two ounces; catheter passed once, and five ounces of urine removed. — 26th (third day): Continues in a most satisfactory condition; ordered small quantities of jelly beef-tea, cold. Wound dressed to-day under the spray in the same manner as at the operation. — 27th: Dressed to-day; one deep and one superficial stitch removed, and stump dusted with persulphate of iron; consumed three ounces of beef-tea in the last twenty-four hours. — 28th: Slight discharge noticed to-day from the vagina; three more stitches removed at the dressing; doing well. — 29th (sixth day): Complained of a sharp pain at 7.30 this morning; temperature then 96.8°. This soon passed off, and she seemed all right till about half-past twelve, when it returned. I saw her soon after one, and found her in a profuse perspiration, and apparently in pain. She complained of a burning sensation in the region of the wound, and I found some blood oozing from beneath the bandage. I immediately removed all the dressing under the spray, and observed protruding from the wound a greenish-black substance which looked like gangrenous bowel, but on investigation it proved to be a clot. This was carefully removed, but fresh blood oozed up in its place, and the manipulation causing a good deal of suffering, she was again anaesthetised, and the whole wound had to be opened up before the bleeding could be stopped. It was found to come from several small vessels in the abdominal wall; these were tied, and some blood being seen in the pelvis, I deemed it prudent to be quite certain that no blood came from there. Finding all secure, I carefully sponged out the pelvis, as at the operation, with soft carbolised sponges, and brought the edges together again with deep and superficial sutures, applying the same dressings as before. A subcutaneous injection of one-third of a grain of morphia was administered. A note made at 9 P.M. says: Patient expresses herself as very comfortable, and seems none the worse for what has taken place; she begs for something to eat and drink, but is only allowed ice. — 30th: Very comfortable; complains of hunger. Ordered jelly beef-tea in small quantities. — 31st: Still complains of hunger, and has become very restless on account of it. Ordered milk as well as the beef-tea. This produced vomiting, which seemed to do her no harm, and she begged for more, so it was given to her. She has had seventeen ounces of milk and four ounces of beef-tea during the past twelve hours.

Nov. 1st: Has been very restless during the night, and not quieted by two hypodermic injections of one-third of a grain of morphia; craving for more to eat. Ordered rusks and milk. Wound looking well; one superficial stitch removed; has been dressed daily. — 2nd: Had an enema to-day

followed by a copious evacuation. Pedicle now beginning to be offensive; carbolic oil painted over and applied on lint round it; two more stitches removed.—3rd: Expresses herself as feeling better; retches sometimes, but does not vomit. We may pass over a few days and note—6th: Had a breast of chicken to-day and enjoyed it; pedicle being very offensive dressed with iodoform and vaseline; all the stitches but two now removed. Sleeps well, and is in no pain.—7th (fifteenth day): At the dressing to-day clamp found to be loose; removed with the stump. At 10 P.M., eight hours after removal, slight retraction of pedicle noticed. Patient's only complaint is hunger, though she is allowed to eat as much as she likes.—10th: Continues to improve; has had a draught of compound senna followed by a copious evacuation. The pedicle is still retracting, and there is a good deal of discharge of laudable pus.—13th: Last suture removed to-day; doing well.—15th: The stump still discharging a good deal of laudable pus; does not seem to have retracted for the last three days. Passed her urine to-day for the first time without use of catheter. Now ordered to be removed to general ward; and from this date continued to progress favourably, and left the hospital for a convalescent institution early in December, six weeks after the operation.

Such, gentlemen, is the history of the case; it is interesting and instructive in several particulars; and I wish to direct your attention to the diagnosis, the operation, the treatment of the pedicle, and the secondary hæmorrhage.

As regards the diagnosis, I dwell on this partly because there is no class of disease in which the diagnosis may be more difficult than in abdominal enlargements, though the nature of some tumours may be readily determined, and partly because all of you when you get into practice, though you may not have to perform the operation of ovariectomy or hysterotomy, will certainly be called upon to give your verdict as to the nature of an abdominal enlargement, and you must not mistake a phantom tumour for ascites, or pregnancy for an ovarian cyst. I dare say some of you are thinking such mistakes are impossible, and no doubt such as I have mentioned are, if ordinary care is used, in by far the majority of cases; but there are instances where careful and experienced surgeons have attempted the operation of ovariectomy and found they were dealing with a pregnant uterus, and there are constantly recurring examples in which chloroform has to be administered, and perhaps an exploratory incision made before the diagnosis is ventured on. In the present case my diagnosis was wrong; but, with the history and condition of the patient, I still think I was warranted in coming to the conclusion I did—viz., that I had to deal with a nearly solid ovarian tumour free from adhesions.

Let us now consider the signs and symptoms in this case, and by a process of exclusion get at our diagnosis. And first we should decide whether we have an actual tumour to deal with, or whether the enlargement is due to ascites, tympanites, or a simple deposition of fat. Firstly, inspection. In either of the three conditions just named the enlargement is more symmetrical; the flanks are distended as well as the front. In ascites the superficial veins are enlarged, and the umbilicus more or less obliterated. In obesity other parts of the body would probably be found loaded with fat; the skin can be pinched up in folds, and on the patient sitting up the belly rolls down on itself towards the pubes. Secondly, manipulation. We note carefully the position of dulness on percussion; in ascites this will be found in both flanks when the patient is lying on her back, and the dull area will alter with the movements of the patient, the resonant parts always being highest. In obesity we find a difficulty in discovering any very resonant part, owing to the thickness of the abdominal wall, and in phantom tumour resonance is found all over the belly, and sometimes, by kneading the parts and taking off the patient's attention, it can be made to disappear; the administration of chloroform will always effect this. Fluctuation is absent in the two last named, and present in ascites, the wave being usually felt all over and at any part of the belly; and if firm pressure be made in either of the above conditions no tumour can be felt, and no more resistance at one part of the belly than another. A vaginal and rectal examination should not be omitted, and in either of the above cases no tumour will be felt. It is evident that this is not either of these conditions.

Now, what are the various tumours we have to choose between? Pregnancy, simple ovarian cyst, multilocular cyst, dermoid cyst, solid tumour of ovary, cyst of broad ligament, fibro-cystic tumour of uterus, fibrous tumour of

uterus, extra-uterine gestation, hydro-nephrosis, malignant or other tumours of kidney, tumour of omentum, liver or spleen, pelvic abscess, hæmatocele, and, perhaps, I should add impaction of fæces in colon and distension of bladder. The exact diagnosis between some of these is sometimes a matter of great difficulty; but in this case we can easily exclude many of them. Distension of bladder: the position of dulness excludes this, and had it been necessary a catheter would have settled the question; and I would venture here to remind you that the symptom of incontinence does not necessarily imply a full or empty bladder, it may occur in either condition. In impaction of fæces you generally get a history of colicky pains, with scanty diarrhoea, or, perhaps, constipation, and a vaginal or rectal examination will remove any doubt. Hæmatocele: the size of tumour and length of time it has been present, and absence of menstrual irregularity. The size, too, will exclude abscess, as well as the absence of febrile symptoms. The history and position exclude enlargement of liver, and in splenic tumours you can generally detect the notch, and the tumour has grown from above; the history and position, too, enable one to exclude omental tumour. Malignant tumour of kidney may be excluded by the absence of hæmaturia and the normal condition of the urine. The hardness of the tumour, as well as the position of the area of dulness (in kidney tumours you find intestines pushed to the other side of the abdomen), exclude renal enlargements. Pregnancy and extra-uterine gestation are excluded by the regularity of the menses, the absence of mammary signs, the absence of foetal movements and heart sounds, and the history. Simple ovarian cyst and cyst of broad ligament are, again, excluded by the hardness and absence of fluctuation; and that leaves us only multilocular or dermoid cyst, solid tumour of ovary, and fibrous and fibro-cystic tumour of uterus. The signs pointing to ovarian tumour are the impairment of the patient's general health, the rapid growth, the smooth surface and elastic feel, with fluctuation in parts, the inability to move the tumour with the uterus when the sound is introduced, and the possibility of raising the tumour out of the pelvis, and the regularity of the menses. Those pointing to uterine tumour: the age of the patient, the symmetrical enlargement, the lengthening of the uterine cavity, and the normal appearance of the umbilicus. I arrived at the conclusion that the case was one of multilocular cyst with a very short pedicle.

As regards the operation, it is one that I think may be fairly said to be yet in its infancy. Ovariectomy was, not many years ago, in the same position, though now it is one of the triumphs of surgery, and a surgeon undertakes such an operation as readily as, say, an amputation of a limb; but till within the last few years there have been very few amputations of the uterus by abdominal section for simple fibroid tumours, and I find a case recorded in an American journal for 1855, where the operator goes into the question whether having opened the abdomen and found a uterine instead of an ovarian tumour, he should proceed to remove it or close up the wound without doing so. In the case there recorded the operation was performed with a fatal result, but not directly due to the operation, and previous to that it had only been performed five or six times. During the next ten years it was performed about twenty times, and as recently as in the year 1866 I think but few surgeons would have knowingly attempted the operation, and many eminent authorities would then, if on an exploratory incision a solid uterine tumour were found, have closed the wound without removal. It is now a recognised operation, and directions for its performance are given in the text-books; the results are such as to warrant perseverance in improving it, and to make it a surgeon's duty to recommend it, not only as a last resource to save life, but to relieve a patient from suffering. As to the method of performing it, the first steps are the same as for ovariectomy, the abdomen being laid open in the middle line, the tumour exposed and adhesions, if any are present, separated, and bleeding stopped; but when we come to deal with the pedicle it is not quite as simple a proceeding. In cases of ovariectomy, I think, most operators agree the best method to adopt is to tie the pedicle—stout silk is the ligature mostly preferred,—cut the ends short, and having removed the tumour, let the pedicle drop back into the abdomen. This does not, as might be supposed, act as a foreign body in the peritoneal cavity, and set up peritonitis, but appears eventually to atrophy and disappear. To treat the stump of a uterus in this manner does not seem

so desirable. The thick more or less elastic substance of which it is composed would be exceedingly likely to shrink in the course of a few hours; this would loosen the ligatures and give rise to internal hæmorrhage, which would not unlikely be fatal, or at the best would necessitate reopening of the abdomen. In all these cases I should prefer to use the clamp, and fix the stump as I did here above the pubes. There are certain objections to the clamp, particularly the amount of traction there might be in the neighbouring parts, especially the bladder, but on the whole, it seems, safer, and you can generally leave enough of the neck of the uterus to prevent undue traction. The uterus may either be removed with the knife or *écraseur*, but when you have the clamp on and have at hand the means of arresting bleeding, should there be any, the *écraseur* seems unnecessarily to delay the operation and to bruise the parts; though should the tumour be too large to draw out at once from the abdomen, it may with advantage be reduced in size by the *écraseur*. In all cases, unless menstruation has quite ceased, both ovaries should be removed, and this may be done by tying their pedicles, cutting them off, and letting the ends drop into the abdomen as in ovariectomy.

As to the secondary hæmorrhage I never heard of a case like this one. There are cases recorded where the patients have died from hæmorrhage at or immediately after the operation; also where the ligature has loosened and there has been bleeding from the pedicle several hours or days after; but here the bleeding was from the divided vessels in the abdominal wall five days after the operation. It was, in fact, ordinary secondary hæmorrhage external to the peritoneal cavity, such as you are always liable to after division of an artery. In clearing away the clots, however, one almost of necessity reopened the peritoneal cavity, there not having elapsed sufficient time for the wound to have firmly united, and even if I had not opened it accidentally I should have been inclined to look into the pelvis again fearing some hæmorrhage might have taken place from the pedicles of the ovaries; but it was evident that the blood in the pelvis had merely trickled down, and therefore after again carefully sponging the peritoneal cavity I closed the wound. The case adds another to the successful cases of hysterectomy, and shows that under proper precautions the peritoneal cavity may be safely manipulated. The use of the carbolic spray is not a *sine quâ non*; on each occasion of opening the cavity it broke down; but antiseptics were freely used all through the operation; the instruments and hands of the operators were carbolised; great care was taken to thoroughly cleanse the peritoneal cavity; and the patient had been, so to speak, prepared for the operation by improving the general health and seeing that the functions of the body were properly performed. It teaches me specially the care one should take in making a diagnosis; and further, that in all operations of the kind one should be prepared for every emergency; for I must confess that I did not commence the operation prepared to excise the uterus; also the care one should take in arresting hæmorrhage in the abdominal wall. I have some doubt whether I thoroughly twisted the vessels after removing the torsion-pressure forceps with which the hæmorrhage was temporarily stopped; and again, I do not know whether the secondary hæmorrhage was not due to the stitches having been removed too soon. Certainly, at the time I thought I had left them in long enough, and that they had done their work, and fearing their presence might have set up irritation; but I was guided too much by what I had seen in one or two cases of harelip, where I had, as I thought, bad results from leaving in the pins too long. In these cases it seems one had better be a day late than a day early in removing the stitches. Lastly, I may say that I saw L. D— about the middle of June, and she was perfectly well and strong, had gained flesh, and was able to move about with ease.

THE French Society for the Protection of Animals has protested against the cruelties practised in connexion with the mode of providing frogs for the dinner-table in France. It appears that when caught the poor animals have the upper part of their legs—i.e., the edible portion—ruthlessly cut off with shears, the remainder of their bodies being carelessly thrown aside as useless. They are stated to have been found, in their mutilated condition, several days afterwards crawling about on their fore-legs. It is time vivisection of this kind, merely to satisfy the appetite of gourmands, should be interdicted.

## ON CONVULSIONS IN CHILDREN.

By EUSTACE SMITH, M.D., F.R.C.P.,

PHYSICIAN TO HIS MAJESTY THE KING OF THE BELGIANS, PHYSICIAN TO THE EAST LONDON CHILDREN'S HOSPITAL AND THE VICTORIA-PARK HOSPITAL FOR DISEASES OF THE CHEST.

(Concluded from p. 6.)

ECLAMPSIA is a symptom which may be serious or not according to circumstances. In estimating the importance of the symptom we must consider the age of the child, the nature and severity of the attack, and the probable cause which has induced it. Infants of a few weeks old often die even from purely reflex convulsions. Older children have a better chance of recovery. After the first few weeks of life much depends upon the cause of the attack. Purely reflex fits and the initial convulsions of acute disease rarely end otherwise than favourably. Again, the convulsions which arise from imperfect aeration of blood, such as may occur in pertussis, are often recovered from; but when the cause is collapse of the lung they are generally fatal. Eclamptic seizures often complicate whooping-cough, and although their occurrence should give rise to great anxiety, the seizures are not necessarily fatal. If the convulsion be the consequence of deficient aeration of blood, the return of free respiration removes the danger for a time; but if the same condition be frequently renewed, the child's state is a very dangerous one. So also convulsions excited by embolisms or congestions of the cerebral vessels, thrombosis of the cranial sinuses, or diffused collapse of the lungs, are very serious. These generally occur late in the disease and are almost invariably fatal. There are two forms of eclampsia liable to happen in cases of whooping-cough which are less dangerous. One of these is due to an exaggeration of the nervous excitement which is an ordinary symptom of the disease. In highly sensitive children it is probably not uncommon for convulsions to take place from this cause, especially if the strength has been quickly reduced by copious epistaxis. So also the onset of an inflammatory complication is often indicated by a convulsive fit, and these attacks, like the preceding, are often recovered from. If, however, a convulsive fit occurs late in the disease, when there is much consolidation of lung, the child seldom recovers. In all these cases it is very important with a view to prognosis to ascertain the mode of origin of the convulsive seizures. If the attack is symptomatic of the onset of an inflammatory complication, it is accompanied by a rise of temperature and followed by a diminution in the spasmodic symptoms and a modification of the physical signs in the chest. If it announces the occurrence of collapse of the lung, the characteristic symptoms which mark that lesion will be present. If the convulsion arises from exaggeration of the nervous disturbance which is one of the peculiarities of the disease, it will have been preceded by signs of unusual agitation in former fits of coughing. Such seizures are only seen in children known to be nervous, sensitive, and impressionable; they follow immediately upon the cough, and between the attacks no signs of nervous disturbance remain. So also in the case of convulsions arising from partial asphyxia; the nervous attack is excited by extreme violence of spasm; but after the fit has passed off no signs of cerebral lesion are left behind. If after a fit there are drowsiness, stupor, squinting, or other sign of nervous disturbance, we may fear that congestion of the brain is present, or that thrombosis of the cerebral sinuses has occurred.

When convulsions appear towards the end of the eruptive stage of measles or scarlatina, they must be looked upon as very dangerous symptoms. Uræmic fits often pass away without producing serious consequences. Whatever be the cause of the attack, stertorous breathing, great lividity of the face with blueness of the nails, or a very rapid pulse should excite the gravest apprehensions. Convulsions from cerebral disease, it need not be said, are of very unfavourable omen; and if they are followed by stupor, squinting, or irregularity and sluggishness of pupils, we can have little hope of the patient's recovery.

The influence which the attack is likely to have upon future brain development is a point of importance, and much anxiety is usually manifested on the subject by the child's relatives. In the commonest case, that in which a rickety child has a fit as a result of some trifling irritant, I believe

the attack to be absolutely unimportant; and familiar as is the experience have never known the patient to suffer from any after ill consequences. So in the case of the other forms of pure reflex convulsions, the eclamptic seizure is due to some temporary condition or set of conditions, which may pass off, if the child survives, leaving the brain unharmed. If, however, the patient belong to a family in which nervous disorders are common, convulsive seizures assume greater significance. If the attacks are often repeated, the prospect as regards the mental development of the child is very unfavourable, for such cases may end in epilepsy or even idiocy. In all cases, too, where the convulsions are connected, either as cause or effect, with some intra-cranial lesion, and where they are followed by signs more than merely temporary of muscular weakness, there is no doubt that for the time the brain is injured by the illness. In cases of recovery, especial care would then have to be exercised in the child's education, so as not to put too great a strain upon his faculties.

When called to a case of convulsions the practitioner should lose no time in questioning the attendants, but should have the child placed in a warm bath of the temperature of 90° F., and apply sponges dipped in cold water to his head. This is the time-honoured remedy. It is certainly an innocent one; it may tend to quiet the nervous system; and it is one the efficacy of which is so generally recognised amongst the public that it would be unwise to court unfavourable criticism by neglecting to employ it. The bath must not be continued too long. In ordinary cases the child should be allowed to remain in it for ten or fifteen minutes, according to his age. If, however, the patient be an infant who has lately been reduced by an exhausting diarrhoea he should not be allowed to remain more than two or three minutes in the hot water, and cold applications to the head must be dispensed with. If the convulsions have ceased when the case is first seen the bath need not be used; but we should not omit to have the child completely undressed, and then to see that he is placed, lightly covered, in a large cot, and that the room in which he lies is well ventilated and not too light. Care should be taken to unload the bowels by a large enema of soap-and-water, and if the child be noticed to retch his stomach may be relieved by a teaspoonful of ipecacuanha wine. In the case of a teething infant opioids differ as to the propriety of lancing the gums. There is no doubt that this operation is a useless one if employed with any hope of hastening the evolution of the teeth; but if the object be to relieve pain and tension I consider the practice judicious, and never hesitate in such circumstances to have recourse to it. If it be desirable to remove all sources of irritation, surely such a source of irritation as a swollen and inflamed gum should not be disregarded. Lastly, if it can be discovered that the child has had pain in the ear, or if the tympanic membrane can be seen to be red, the ear should be syringed out and fomented with hot water, and, if thought desirable, a leech may be applied within the concha, the meatus being first plugged with cotton-wool.

If, in spite of these measures, the convulsions return, or signs are noticed of continued irritability of the nervous system, it is best to administer a dose of chloral. Two or three grains can be given to a child between six and twelve months old; and if the patient be unable to swallow, half as much again may be administered by the rectum dissolved in a few teaspoonfuls of water. If necessary, the dose can be repeated two or three times a day. Bromide of ammonium and belladonna are also largely employed in these cases. The former can be given in three or four grain doses every two hours to a child of from six to twelve months old; the second in ten or fifteen drop doses two or three times a day to a child of the same age. Infants are so tolerant of this drug that it should be given to them in a dose which can produce some appreciable effect. In the convulsions of whooping-cough where the spasm of the glottis is extreme, treatment by bromide of ammonium or potassium is especially indicated. The bromides are well borne by quite young children, and we should not fear ill consequences from what may appear a very large dose. Chloroform is often employed, but it is decidedly inferior to chloral and much more troublesome.

If the child have been lately the subject of exhausting discharges warmth should be employed, and stimulants, such as the brandy-and-egg mixture of the British Pharmacopœia, be given energetically. If the convulsive attacks are followed by signs indicative of intracranial mischief,

such as stupor, squinting, ptosis, &c., the child should be kept quiet and an ice-bag be applied to his head. In all such cases the treatment must be conducted according to the condition from which the convulsion is supposed to have arisen.

When the convulsions have ceased, and signs of irritability of the nervous system are no longer to be observed, we must take steps to improve the general condition of the patient. His bowels should be attended to, and his diet be carefully regulated. If rickets be present it must be treated. Most children in whom the convulsive tendency exists are benefited by iron wine and cod-liver oil, for their nutrition is usually at fault, and both the alcohol and the iron contained in the wine are beneficial, while the oil is of the utmost value in supplying nutritive deficiencies. Fresh air, too, is of the utmost importance, and the child should be warmly dressed and be taken regularly out of doors.

## OSTEAL OR PERIOSTEAL CACHEXIA AND SCURVY.

By W. B. CHEADLE, M.D., F.R.C.P.

IN a clinical lecture which appeared in THE LANCET in November, 1878, I described cases of special cachexia occurring in young children which correspond most closely with those recorded by Dr. Gee, under the title of "Osteal or Periosteal Cachexia," in the last volume of the St. Bartholomew's Hospital Reports. In all there was the same underlying condition of rickets, with a cachexia beyond the common, marked pallor, extreme muscular debility, spongy gums, hæmorrhages, œdema of the extremities, and in one instance swelling of the periosteum of the long bones. These were unaccounted for by any disease of the lymphatic glands, liver, or spleen; and I showed, as I think conclusively, that the morbid condition was that of scurvy, supervening upon rickets, produced solely by a diet which was a scurvy diet, in addition to being certainly rachitic, the disease being cured absolutely and immediately in every instance by antiscorbutic diet. In an annotation in THE LANCET of the 24th ult. a similar view is taken of the nature of the cases described by Dr. Gee. Since 1878 I have seen three more cases of the kind—two in the hospital in Great Ormond-street, and one in private. They arose under similar conditions of diet, and recovered at once under antiscorbutic treatment. In one of these the periosteal swelling was so marked, the resemblance to the so-called "osteal or periosteal" cachexia so complete, and the result of a simple change of diet so striking, that the case is worthy of publication now that the subject is exciting interest and discussion.

*Scurvy in a child of ten months fed on Nestle's food; extreme cachexia and muscular debility; periosteal swellings; œdema of the legs; albuminous urine; hæmorrhagic, spongy gums; rapid recovery on antiscorbutic diet.*—C. G—, a full-sized boy of ten months old, the second child of well-to-do parents residing in a healthy suburb, first seen on November 11th, 1881. He is emaciated, extremely anæmic, with an earthy complexion, pallid and cachectic. The muscles are remarkably flabby and soft, and the child so feeble that not only is it unable to sit up, but it cannot even lift up its head, lying perfectly limp and almost motionless, although restless, irritable, never sleeping more than half an hour at a time, and crying at the least touch or movement. He is evidently tender and dreads being handled; most tender of all in the legs, especially the right, which is greatly swollen. This is found to be due chiefly to swelling of the periosteum of the tibia, which extends from half way below the knee in front to the ankle. There is a similar tender swelling, but smaller, on the left tibia. Both feet and ankles are œdematous, but show no petechiæ. The gums of the upper jaw in front are greatly swollen, protruding, spongy, purple, and bleeding. The lower gums in front are slightly swollen and marked by ecchymotic stains. The child has rickets; both ulnæ are much curved; the ribs beaded; the ends of the long bones enlarged; the chest compressed laterally; the fontanelles widely open; no bosses on the skull; no enlargement of the lymphatic glands, spleen, or liver. There is no sign of congenital syphilis. The lung and heart sounds are feeble but natural in character. The urine contains a cloud of

**albumen.** The temperature is slightly subnormal, 98°. There has never been any eruption or snuffles, nothing suggestive of congenital syphilis. There has been no vomiting or diarrhoea for the last four months. The child takes food greedily and in large quantities. The child is always hungry. The history given by the mother is as follows: The child was fine and healthy when born, and for the first two months thrived on a diet of half cow's milk and half water, sucking out a scanty supply of breast milk. At the age of two months the child was placed on Nestle's food. It remained well until it was six months old, when it was seized with severe vomiting and diarrhoea attributed to sunstroke. After this the child was fed for a time on arrowroot and isinglass; no milk. At seven months old Nestle's food was again resorted to, on which it has been fed entirely ever since—i.e., for the last three months. It has grown more and more pallid, feeble, and miserable. I directed the child to be placed at once upon a diet of half milk and half water, thickened with fine potato gruel and prepared bread. It was given in addition a small quantity of raw meat pulp and half a teaspoonful of brandy in a tablespoonful of the food every two hours. No medicine in the shape of drugs of any kind was given. Three days later, when the child was next seen, there was already marked improvement. The child was less tender on being handled, began to move its limbs about, and slept several hours at a time. The temperature had risen to 99°. In a week the periosteal tenderness and swelling had sensibly declined; the gums had ceased to bleed, and were only slightly purple and swollen; the oedema had almost disappeared; there was still a trace of albumen in the urine. At the end of a fortnight, on the new diet, the gums had become normal, the oedema had gone, and the albumen had disappeared. The periosteal swellings of the tibia were still perceptible, and the limbs were tender, but the child now kicked its legs about, and was clearly gaining ground every day. At the end of three weeks it could sit up, was putting on flesh rapidly, and regaining colour. The swelling on the right tibia had completely gone; there was still some fullness of the left tibia, but no tenderness anywhere. From this time improvement proceeded most rapidly, until the child grew perfectly robust and healthy-looking, and thus remains, the only change which had been made in the management being a change of diet.

This case is closely parallel to those recorded by Dr. Gee. I think there can be no reasonable doubt that the condition was one of scurvy supervening on rickets. This had arisen on a diet of Nestle's food, aided by an original drain from vomiting and diarrhoea, with a course of arrowroot and isinglass; but for three months Nestle's food had been the sole diet. Every addition had been strictly prohibited, for fear of bringing back the vomiting and diarrhoea. If Nestle's food was not the prime cause of the scorbutic condition, it was clearly powerless to remove it; yet it professes to contain a sufficient amount of milk, and milk, at any rate fresh milk, is an excellent antiscorbutic. I have more than once observed the rickety state creep on under a strict diet of this food, and the case just related shows further the inadequacy of this preparation alone for the supply of the full elements of nutrition.

Hyde-park-place, W.

## ACUTE IDIOPATHIC ARTERITIS; GANGRENE OF EXTREMITIES; DEATH; AUTOPSY.

By S. A. K. STRAHAN, M.D.

THE difficulty, approaching impossibility, of noting with anything like accuracy in an acute maniac the onset of an affection in which the symptoms are mainly or entirely subjective is well known. That patients in a state of acute mania frequently suffer—if I may use the word—from the most painful affections without once complaining or even speaking of their illness, is a fact recognised by all asylum physicians; and this, coupled with the frequency with which men in this special branch of the profession meet with cases of well-simulated, imaginary disease, may be taken as an explanation of why they put so little confidence in subjective symptoms, resting their diagnoses chiefly on physical signs. In the present case it cannot be doubted that had the patient

not been deprived of her mental faculties the disease would have been detected earlier; and although it is questionable whether any treatment would have averted the fatal termination, it is to be regretted that it was not sooner discovered, inasmuch as it would have given a better opportunity of noting in its entirety the clinical history of a very rare form of disease.

E. G.—, a female patient, aged forty-nine years, under treatment for relapsing mania, was on Feb. 4th suffering from an attack of acute maniacal excitement, the usual sedative remedies being administered.—5th: Condition unchanged; violent and destructive, requiring constant attention of two nurses. Was walked round court two hours between nurses. On coming in patient was, the nurse said, "taken very cold and trembled." Patient was put to bed between blankets, and, when seen by the medical officer a very short time after, was in much the same condition as in the morning—viz., restless and excited, striking anyone within reach, shouting, tearing her bedclothing, &c. Ordered a draught containing forty grains of bromide of potassium and twenty grains of chloral hydrate.—6th: Had a restless but fairly quiet night. She did not, as on former occasions, attempt to leave the bed. Still, in a state of acute active mania. The right leg was now discovered to be quite cold up to the knee, the skin being pale and mottled with purple. Volition and sensation lost. No pulsation could be detected in popliteal space. The left foot and half way up the tibia were in a similar condition. In the left leg pulsations could be felt in the popliteal artery, but nowhere below that situation. The left hand was markedly colder than the right, and no radial nor ulnar pulse could be felt; this hand she was using vigorously. Pulse at right wrist 96; small and weak. Temperature in right axilla 100·2°. The chest was carefully examined stethoscopically with negative result. The limbs were wrapped in soft flannel. Opium ordered in grain doses every three hours, and milk, beef-tea, and small quantities of whisky. 5 P.M.: Pulse 100; temperature 100°. State of right leg unchanged. Heat now present in left extremity as far down as the ankle and sole of foot of a dark purple. Temperature of left hand still very much below that of right, and looks pale. No pulsation can be felt below the axillary artery, and there are signs of pain on pressure over the course of the brachial artery, but no swelling or discolouration. She uses the left arm freely and throws it about much more than the right, which is in all respects normal.—7th: Had a restless night, tossing about as if in pain, but not speaking. Took some food and alcohol. Temperature this morning in axilla 100·6°; pulse 140, thin and feeble. Left arm, which was tossed about much during the night, seems warmer to touch than it was, but is still below 95°, the lowest the thermometers (two) used register. Pulse can now be felt at the elbow, and not below that point. Hand looks anemic beside the other. No discolouration. Right leg darker in colour, upper surface of foot very white, toes purple. Line of demarcation seems to be forming immediately below the patella. Severe pain, causing the patient to cry out on pressure being made over the femoral artery as it passes from Hunter's canal to the popliteal space. No pain above this part, no pulse in popliteal. Left foot, cold as before; upper surface of foot deep purple, toes white. Pulsations easily felt in popliteal in this limb, but nowhere below that. Severe pain on moving either leg. Bowels acting. 5 P.M.: Little change in general condition. Has not spoken since morning. Takes nourishment in minute quantities. She is fairly under the influence of the opium. Has lain in a restless troubled sleep the greater part of the day. Pulse 144, fluttering. Sordes on teeth; eyes becoming sunken and glazed. Right leg as described this morning except that the line of demarcation is better defined. Pain over femoral as before, and confined to the same part—viz., the first three inches above the knee-joint. Left foot appears as in the morning, but now there is severe pain on pressure over the anterior tibial artery in its lower half. Toes of both feet flexed and freely movable. Left hand and forearm remain in the condition described this morning.—8th: She passed a restless night, gradually sank, and died at noon.

**Autopsy.**—Twenty-six hours after death an examination was made of the body. The result is summed up in the following brief notes:—Cadaver that of a well-built, well-nourished woman of about fifty. Some slight ecchymoses on arms and forearms. Left leg and foot, from knee down, of a deep purple mottled with white. Right foot purple, with well-defined limit just below the ankle-joint. Palm of left hand slightly purple. Rigor mortis well-marked in all parts

of the body, except in the parts of lower limbs mentioned above as being discoloured, in which the joints were perfectly flexible and the muscles soft and flabby. Head: The dura mater was somewhat congested, as was also the pia mater, and there was some milky opacity of the arachnoid over the apex of the hemispheres. The brain weighed  $54\frac{1}{2}$  ounces, and had an abnormally plentiful show of puncta vasculare. In all other respects the contents of this cavity appeared healthy to the naked eye. There were no signs of atheroma in the arteries at the base. Chest: Lungs emphysematous to a large extent in their anterior and inferior borders. No fluid in pericardium. The heart weighed  $10\frac{1}{2}$  ounces, all valves competent. The cardiac muscle was fairly firm and appeared healthy, as did also its lining membrane, which was in all parts smooth and glistening. Right auricle almost completely filled by a yellow, fatty-looking clot. Right ventricle contained a much smaller clot of like character and some blood, while the left side of the heart was gorged with black fluid blood. The aorta, which was full of blood similar to that in the left heart, appeared perfectly healthy. Abdomen: Spleen rather soft and friable and dark-coloured; liver congested; all the other organs appeared normal except the uterus, which was retroflexed. The right femoral artery at the seat of pain during life was cut down upon and removed for about three inches of its extent. It was easily found, as it was hard and round, almost as though the body had been injected for dissection. Black, tarry blood flowed slowly from the upper end of this section of artery, while the lower end of it was filled by a black plug of coagulated blood, which kept its form on being squeezed out. The wall of the artery was highly injected, had lost to a great extent its natural elasticity, was thickened, and had a harsh, leathery feel. On its being slit up its lining membrane was found to have lost the smooth, glistening surface; it was rough, of dark-red colour, and covered, especially in its lower half, with hard nodules of black coagulated blood, which would not wash off, but remained firmly adherent to its lining membrane. As permission to examine the body was only obtained after it had been duly promised that nothing would be done beyond that necessary to ascertain the cause of death, none of the vessels in the other affected limbs were examined.

*Remarks.*—This case is interesting as being a remarkable example of a most rare disease. There can be no doubt that in former times the post-mortem staining of the inner coats of arteries was often mistaken for the injection of the vasa vasorum found in true inflammation of the arterial walls, and there is equally no doubt that, although idiopathic arteritis was formerly suspected in many cases where no real inflammation of the vessels existed, it may and does occur in rare instances. The disease in this case was marked at its onset by a distinct rigor, for such I consider the "being taken very cold" described by the nurse on the first day. The temperature from the second day was above  $100^{\circ}$ , which is not high considering the extent and acuteness of the inflammation; but with this we must remember that our patient was an acute maniac—that is, one in a state in which the usual effects do not follow disease; one in whom the nervous system, and in fact the whole organisation, is so numbed that causes sufficient to produce marked changes in the ordinary state of the system pass unnoticed. The clot found occluding the artery was made up simply by coagulation of the contained blood. True, this may have only been a clot formed by coagulation above another formed by exudative material further down in the vessel; but this is extremely unlikely, because, in the first place, it was within two inches or less of the line of demarcation between the gangrenous and other tissues, and gangrene rarely extends so high as the point of obstruction in the main artery of a limb; and, secondly, it is an open question whether the lining membrane of an artery can at all pour out an exudation into the blood current. Virchow proved by experiment that a vein empty of blood might be irritated and no exudation take place from its lining membrane although its wall became infiltrated, and we know of no reason why the same rule should not apply to an artery. It is quite possible that the tissues of the arterial wall may participate in the inflammatory state, and without exuding any morbid or other material into the cavity of the vessel, conduct to the blood some coagulating influence. Again, given an artery filled with coagulum, and the patient continuing to live, we have, as one mode of termination, contraction of the vessel, a gradual change in the clot and the vessel's walls like that known to occur in other parts of the

body, and ultimately nothing left but the fibrous cord which is sometimes found, and upon which the theory of the pouring out of exudation was to a considerable extent based. As to the cause of the affection, I believe no more can be said than that it is a morbid state of the system, which expresses itself in this particular way, as pneumonia depends upon some other morbid state, which makes its presence known by solidification of the lung. All the authorities I have consulted agree that arteritis generally appears in persons beyond the middle age and of broken constitution. That the disease should in this case attack more than one vessel or limb, though strange, is not any more wonderful than that pneumonia should in some cases attack both lungs, or that rheumatism may in one case attack a single knee or shoulder-joint, and in another case both knees or both shoulders. Had not the heart and aorta been examined there would have been room for grave suspicion of embolism, but I think the autopsy, incomplete as it was, excludes at once all but arteritis.

Berry Wood, Northampton.

## THE PRIMARY STAGE OF ANEURISM (SUBCLAVIAN) AND ITS DIAGNOSIS DURING LIFE.

BY J. MILNE, M.B. & C.M. UNIV. ABERDEEN.

CLINICAL authorities in writing and teaching so frequently ignore the possibility of the detection and diagnosis during life of an aneurism in its early and pre-sacciform stage, that I have thought the following interesting case, illustrating as it so well does the opposite view, well worthy of publication. With the advanced state of auscultatory science the modern physician has, perhaps, a tendency to attach more importance to the objective than to the presumptive signs of intrathoracic disease. In the alternative that presents between two diseases more might assuredly be done in diagnosis than often is by patiently weighing and considering carefully the *pros* and *cons*. The case I write of is that of a man who consulted me on July 31st, 1876, and the fact of his having died some days ago in the Bristol Royal Infirmary has led me to overhaul and publish extracts from my notes as entered at the time in my clinical diary.

J. M.—, aged twenty-eight years, consulted me on July 31st, 1876. States that he has been under the care of a local surgeon for a couple of months, and that he has been treated by that gentleman for functional disease of the liver (that much maligned organ) and other ailments, considered trivial, and attributed to cold. Influenced by what the patient told me, I did not, on this occasion, institute any special examination, merely prescribing a mixture with chloric ether and compound tincture of camphor. I desired the patient to call again, so that I might more particularly examine him.

August 3rd, 1876: Patient called. Reports himself no better. Complains of pain under the left clavicle when he moves his arm. States that the pain shoots down his arm in twitches. Tells me that the pain is not in any way aggravated by percussion or pressure. Complains particularly of pain over the costal cartilages of the right side, about two and a half inches below the right nipple, "a severe beating and swelling sort of a pain," to use his own words, "on the breast." A whiffing bruit is heard and visible pulsation is obvious, at the outer part of the left subclavicular region. Auscultation fails to show any pulmonary or cardiac mischief, save that the second sound of the heart is sharp. Taking all things into consideration, I suspect aneurism.—5th: In conjunction with my friend, Dr. Inlay, of Clifton, to whom I had explained in detail the several symptoms elicited, we both agreed in the validity of the following reasons that aneurism of the third portion of the subclavian artery was the nature of the disease: 1st, that the second sound of the heart is sharp; 2, that the patient complains of pain at the outer extremity of the left infra-clavicular region; 3, because neuralgic twitches of pain shoot down the left arm, evidently from some pressure on the brachial plexus; 4, that the venous radicles on the left shoulder are enlarged much more than on the corresponding shoulder; 5, much greater fulness, apparent to the eye, under the left than

under the right clavicle; 6, that there is distinct visible pulsation in the last-named site; 7, that there is uniform bulging of the artery on applying the finger; 8, that a distinct whiffing bruit is audible under the left clavicle on applying the stethoscope, as also the ear, by immediate auscultation; 9, that there is striking arrest of the radial pulse on the left side, almost approaching to complete suppression, and obviously pointing to some obstruction on the cardiac side. We want, however, two links to complete the diagnostic chain of argument for aneurism: (1) Dulness, which, by tactile percussion on the affected site, we fail to demonstrate; (2) the presence of a distinct aneurismal tumour. The two absent symptoms do not, however, militate against aneurism, but against aneurism in an advanced stage. Bruit, pressure symptoms, such as pain, venous congestion, and fulness under the clavicle, may be caused by primary dilatation of the artery, or by fusiform aneurism so-called, just as congestion of minute arterial capillaries may by pressure on nervous filaments in any part of the body cause pain. Taking into consideration the possibility of the cure of aneurism, especially in its earlier stages, by iodide of potassium, as advocated by the late Drs. Begbie and Bennett, of Edinburgh, and surmising that the co-operation of the patient himself would be a necessary accessory to the cure, I deemed it better to acquaint the patient and his friends with the serious nature of the affection, as by so doing I could inculcate on the patient's mind habits of the strictest temperance, and successfully enjoin on him the necessity of avoiding any exciting or violent exercise. I remembered that my patient had a penchant for quoit-playing, and occasionally for wrestling. I postponed, however, and withheld from him the result of my diagnosis and prognosis consequent thereon, till another examination should quite preclude the possibility of any fallacious assumption.—7th: Dr. Imlay and I again subjected the patient to a strict examination, with the result of mutually confirming our former observations. Strange to say, by means of the percussion hammer of Hughes Bennett, of Edinburgh, and a pleximeter, I demonstrated on this occasion, to the satisfaction of Dr. Imlay and myself, marked dulness over the suspected site; tactile percussion, as stated August 5th, 1876, having failed to elicit this important symptom. The dulness exists in a circumscribed patch at the outer extremity of the left subclavicular region. At this date the absence of a distinct tumour alone is wanting to complete the diagnostic chain; yet in the face of so much affirmative evidence for aneurism, albeit that one solitary symptom is absent, it is impossible to refrain from concluding that we have to deal with the first stage of a fusiform aneurism, involving the third portion of the subclavian artery on the left side.

*Treatment.*—The patient must desist from quoit playing and any violent exercise, as also from any excitement; to observe perfect rest and quiet, and to abstain from stimulants; to take half an ounce of the following mixture in water night and morning for six weeks: tincture of digitalis, two drachms; iodide of potassium, three drachms; clove water to eight ounces.

Oct. 9th: Symptoms still present. One symptom, the whiffing bruit, is perhaps not so marked on this inspection; it can, however, still be heard. The pulse at the left wrist is all but suppressed. The patient has been in Scotland, but instead of consulting, as I advised him, Dr. Gairdner, of Glasgow, has taken the opinion of a country surgeon in the North, who told my patient that he had no aneurism, but that "his blood had got glued and sticky in his veins from cold." It is to be regretted that such rough-and-ready diagnostic opinions are but too commonly given. Sir Wm. Fergusson says of aneurism, p. 147, "Practical Surgery," third edition: "I have myself watched one of undoubted character on the axillary artery for several years, and could observe no perceptible increase in its size; and examples where spontaneous cures have occurred within a certain period might also be adduced." That there is a possibility of the cure of aneurism, even in advanced stages, many well authenticated cases attest; much more, then, are we entitled to hope for a cure when the aneurism is in its pre-sacciform phase.

At this date (Oct. 9th) I am satisfied that the case has been (if it be not now) a genuine case of the diagnosis of aneurismal dilatation in its initial stage, and I am likewise satisfied that if the patient do not present to subsequent examiners the symptoms of an aneurism, he has to thank me for my diagnosis of Aug. 7th, 1876, and the drug called iodide of potassium for his recovery.

Bedminster, Bristol.

## REMARKS ON BILHARZIA.

By DR. JAMES F. ALLEN.

THE bilharzia is of peculiar interest to the colonists of South Africa. All our streams and rivers are more or less infested with it; it is to be found in persons resident widely apart, in the Cape Colony, Free State, Transvaal, and Natal, not only in these colonies and States, but also far in the interior; indeed, it is pretty evident that it is to be found in the rivers of the whole continent, from Egypt to the Cape of Good Hope. Some time ago I was consulted by a gentleman who had returned from a hunting expedition in the interior, several hundred miles beyond the regions occupied by white settlers. He was first troubled with hæmaturia, due to the bilharzia, while camped on the banks of the Zambesi.

In this part of Africa (Natal) the persons principally affected are the children of the white settlers and natives. The reason is very evident; they are the largest consumers of unfiltered water. It is not so often found in girls, they staying at home more than as a rule get filtered water; boys and natives, living much in the veldt and drinking copiously from the first stream they come across, soon imbibe it. The symptoms produced by the bilharzia are therefore so common that almost every lad suffers or has suffered from hæmaturia. So general is this symptom among boys that they often do not think it necessary to mention it to their parents. Unfortunately the medical profession in this part of Africa, in common with the profession in general, have as yet failed in their efforts to eradicate this parasite. For these reasons one is not often consulted primarily about the bilharzia, therefore to obtain any information one must collect it by close inquiry, and if possible by adopting some successful means of treatment; the best that could be done up to the present was but a kind of expectant treatment: support the patient's general health and wait. It was more than probable he would be quite free from the parasite before he was twenty. In the majority of cases this would be correct, but in the meantime the child's growth is going on. This constant loss of blood sets its stamp on his appearance; tall, perhaps, but narrow-chested, pallid, without energy, mental or physical, they become a source of great uneasiness to their parents. It is at this period we are generally consulted. Sometimes no mention of the real cause of the mischief is made until after close questioning. It is not uncommon to hear parents express their surprise at hearing for the first time that their children are suffering from this parasite; others know of it, and, as I have said, think nothing can be done; the loss continues. Soon, in this warm climate, the majority of colonial-bred lads of pure European descent assume a cachectic appearance with weakened frames, which will seriously affect the physique of the future pure white race in South Africa. I mean by pure white those persons who have not the blood of one or other of the black races in their veins. Most of the Dutch of the Cape, Free State, and Transvaal would find it hard to clear their pedigree of "black blood." The result is that at the present day these men, although they suffered from the bilharzia in their youth, have an immunity from its after-effects, due in all probability to their being on that account better able to bear the climate. The natives, to judge from their appearance, are also blessed in this way.

Finding this little parasite likely to become of great importance in the future of this country, I set about making attempts to destroy it. I also inquired closely into the history of those who had become free from it, especially the time immediately before its disappearance, and the circumstances which they believed led to this happy result; also into the symptoms the presence of the parasite produced. These consisted, in the great majority of cases, in the passage of a few drops of blood after urination. Sometimes this hæmorrhage is increased to several ounces, and is nearly always accompanied with a rigor, sometimes also with pain and irritation of the bladder. This is followed by anæmia and all its consequences; most of the persons were affected "as long as they could remember." When the hæmaturia had disappeared they could not recall; perhaps when they were fifteen or sixteen years old. They had never paid much attention to it, having suffered from their early

childhood, as long almost as they could look back upon; they had nearly come to regard it as a natural sequence to the passage of urine. Their friends were afflicted in a like manner, and had recovered; they also hoped to become free from the unpleasant symptoms as they grew older. Such is the sum of the information generally received. It is a remarkable fact that in by far the greater number of cases the parasite does disappear at puberty.

The history in other cases pointed to something much more definite: an acute illness of some kind, chiefly the typho-malarial fever sometimes prevalent here, had intervened. When the child recovered the parasite was destroyed. In girls the appearance of the menses and disappearance of the hæmaturia are often apparently simultaneous; if not, should the girl become pregnant, the parasite is almost certain to disappear. Changes of residence and climate have sometimes the desired effect. In this country the parasite is very liable to re-enter the vascular system. Even those who have suffered for years from it are very careless and unguarded. This reoccurrence, "or relapse of the disease," as it is commonly called here, adds to the evidence in the mind of the sufferer of its incurability.

There is one important fact with regard to persons afflicted with this parasite which must not be overlooked, as it is not without consolation to them. I have never known or heard of anyone in this part of Africa dying from its effects, and although it circulates throughout the whole body with the blood, as we are led to believe by authority on the subject and by observation of the history of individual cases, I have never heard of its taking up a permanent position in any other part of the body than in the bladder. I have been for the past six years surgeon to Grey's Hospital in this city, and have never seen a case in which it was found elsewhere. It is quite certain that if it did take up other positions, it would at once call attention to its presence. There is hardly an internal organ in which it could be less dangerous, and there are others, such as the heart and brain, in which it would be fatal.

When it is taken into consideration how common it is, and, of course, the great number of people who suffer from it, this persistent and only appearance in the bladder is an important fact; it may be the case that the bilharzia, though free of access to all parts of the body, can only exist in its final state in the bladder. If such is the case, and I think we have good grounds to believe it is, much of the formidable history connected with this little animal is at once deprived of its terror. It is clear that the parasite is perfectly harmless while circulating in the blood—at least, there are no symptoms which point to its presence there; in fact health is perfect until the hæmaturia appears, and thus shows it has taken up its final settlement in the bladder. It is, therefore, in its final state dangerous, and that only in a remote degree. This was brought prominently forward in the last case I treated.

A boy came for advice suffering from profuse hæmaturia; he had had it as long as he could remember; was weak and pallid; he described the blood as running from his urethra after micturition. This was accompanied with much pain and rigors; the boy was thin, but tall; every bone in his body was painfully visible. After I had killed the parasite in this boy's bladder his appetite, which had left him, quickly returned; he ate ravenously, regained his health and spirits, and continued to improve steadily, although I did not attempt to poison the parasite in his blood for some time after the hæmaturia had disappeared. Not once during that time had he a symptom of any kind that pointed to the presence of anything abnormal in his blood. This fact I must bring forward prominently as it gives to the local symptoms much more importance. I fear we have been more or less entirely taken up by the thought of the parasite circulating in the blood, and in our hopelessness about it in that situation it seemed to us of little use destroying it locally in the bladder when it was present in the general vascular system. We took the hæmaturia as the continued evidence of its presence there after all kinds of different treatment, which really never affected the parasite in the bladder in the least, though it may have killed it in the blood. The truth is that if we had first poisoned it in the bladder and then tried constitutional treatment we would have been more successful. As the local deposit and its results cause the cachexia, if we could get rid of them by any means we would relieve our patients of their worst symptoms, and as far as the parasite is concerned (the only one perhaps in some cases) effect an entire cure, especially in persons who have left Africa for a

colder climate. This I offer as a suggestion to those who may undertake the treatment of such cases in England.

It is very evident from the foregoing that anything which alters the condition of the blood, changes so subtle as to escape all detection, and yet the most fatal to it, are those which take place at puberty. More material alterations, those that take place during pregnancy, or, in acute illness, the specific poison of fevers, or perhaps the increased temperature or changes in the specific gravities, it may be through the laws of osmose and exosmose, are quickly fatal to this little animal. Whatever it is, we know as a result that the bilharzia is often killed by spontaneous causes. I think, therefore, we may fairly come to the conclusion that this parasite is not all-tenacious of life. This fact once proved gives a much more hopeful view to our position; the whole case assumes quite a simple appearance. That which nature so easily performs sometimes, as far as we can tell, without any external influence or material change in the blood, ought to be within the limits of our power, possessing as we do poisons fatal to insect life; we have only to bring the parasite and the poison together, without prejudice to the rest of the body, and we will succeed in all we desire. I have tried to bring the different points in this subject gradually forward as they have come before me in actual practice. I was in despair at first at the thought of this animal living and thriving in the blood of unfortunate people. It may live there; but I think that the history of the persons affected with it prove beyond any doubt it does not thrive there.

Having slowly and carefully arrived at these conclusions, after sifting a mass of evidence, I at last determined to adopt some of the hints I had received from nature. I had wasted much time in treatment. I had as yet only administered remedies by the mouth—astrinents, ergot of rye, and tonics of different kinds; of these the tincture of the perchloride of iron gave the best results, only as a tonic, not affecting the hæmaturia. Lastly, anthelmintics, of which I used oil of turpentine and santonine only; with the former I produced strangury, and nothing else, as far as I could see. Santonine I gave in full doses, five grains every morning, until I brought on the therapeutical effects of the drug, some of my patients seeing everything yellow, in a more or less degree, and nausea and vomiting being produced in others, without the least benefit to the local symptoms in the bladder. I have since learned that in those to whom I gave santonine in full doses I killed the parasite in their blood, although its presence in the bladder remained, and was still the cause of all the distress. Finding the hæmaturia remain in this obstinate manner I determined to try the effect of injections into the bladder. I resolved to use santonine in the first instance, as I believed it would be fatal to the bilharzia; for this purpose I made a saturated solution of santonine in absolute alcohol, knowing the spirit would be very efficacious for the purpose I required. I selected the case of a lad who applied for treatment at Grey's Hospital. He had suffered from hæmaturia as long as he could remember. In appearance he was very thin and anæmic. He was born in the colony, but was of pure European parentage. He was apprenticed to a carpenter, and found he was getting too weak to work at his trade. I injected into his bladder half a drachm of the solution of santonine and alcohol, using for the purpose a subcutaneous syringe from which the needle had been removed, and a small gum elastic catheter, filling the end of the syringe to the catheter so that none of the solution should escape. I then made him lie on his back for about an hour and retain the solution. The injection was followed by acute inflammation of the bladder; this subsided quickly under the influence of tincture of hyoscyamus and infusion of buchu, with as much barley water as he could drink; he passed considerably more blood during the first attack of cystitis than he had done before. I repeated the injection in this case four times; each time it was followed by acute cystitis; each time the quantity of blood discharged became less, until at last it disappeared. I then gave him five grains of santonine every morning with the intention of poisoning the parasites in his blood. The symptoms of cystitis lasted only twenty-four hours; in other cases I have treated since it has continued much longer, sometimes for three or four days. I attribute this to the fact that I had used larger quantities of the injection in my later cases. I had the satisfaction of discharging him cured, to all appearance, after a treatment which had lasted only fourteen days. He went away to the Free State, promising to write if the blood reappeared. I

have not heard from him since, and therefore conclude that he has continued well. Since then I have treated many cases, so that I have ceased to take note of them, and I have been invariably successful.

I can confidently recommend this treatment; the cure is well worth all the suffering consequent upon the inflammation of the bladder. The only difference I have since made in the treatment is that I inject two drachms of the solution at a time; the patient sometimes complains of feeling drunk, the alcohol affecting the brain.

The points to be careful about are (1) the bladder must be empty of urine; (2) the solution must be injected into the bladder; it sometimes escapes unless care is taken to make the joining of the syringe and catheter secure; (3) the patient must retain it as long as he possibly can. I have never treated a woman or girl in this way, but I have no doubt it would be as successful as in men and boys. As yet this is but a crude statement. I would like to be able to tell more about the parasite after it is ejected from the bladder in the urine. I have as yet failed in making any satisfactory investigations in this direction; in the future I may be able to finish my inquiry. I have never found anything more serious than the inflammation resulting from this treatment; it is painful and requires great resolution on the part of the patient. I adopt it always without fear, and as yet have had the best results.

Pietermaritzburg.

## ACUTE STRANGULATION OF THE SMALL AND LARGE INTESTINES.

BY M. C. SYKES, L.R.C.P. LOND., M.R.C.S.,  
HOUSE-SURGEON, BECKETT HOSPITAL, BARNSELY.

A. N.—, aged ten years, was admitted into this hospital on February 6th, suffering from a compound fracture of his right forearm, a wound over his left eye, and a slight contusion below the left Poupart's ligament. On admission he complained of pain in the hypogastric region, which was relieved at once by drawing off his urine. The wound of forearm and eyelid healed in six days. He had no pain after the first night. His bowels were regular, he passed his urine, and appeared ready for sending home. He was sent out on Feb. 18th. On arriving home he had some cakes and tea given him; this would be about six in the evening, and at one o'clock the following morning he was seized with pain, followed by sickness and diarrhoea. I saw him the next morning. He had been sick all night; no diarrhoea or motion then complained of. He had pain in the right iliac fossa; the pain was not very intense. Nothing could be felt. I saw him again on the following morning. The symptoms had increased: hiccup; abdomen tense; vomited food and medicines; no pain. I saw him again the next morning, being the fourth of the disease. He vomited a great deal; hiccupped; abdomen tense; no pain. He had not had a passage since the first attack of diarrhoea. He died during this visit. His temperature was never more than 99.4° F.

I made a post-mortem examination, and found the following morbid changes:—A piece of the small intestine, ileum, was perforated (no escape of feces), and had formed adhesions to the ascending colon. It was also strangulated here by recent inflammatory bands, and also slightly twisted. The bowel here was empty. The commencement of the large gut was constricted by bands of fibrous tissue crossing it, and connected to the iliac fossa, and thickened by inflammatory products. It was completely strangulated by one of the bands of fibrous tissue, and closed off from the general peritoneal cavity by local peritonitis. A collection of pus was also enclosed by the peritoneum around the upper portion of the cæcum. There was not general peritonitis; it was localised entirely to the right iliac fossa. There was no other visceral mischief or disease of the bones or a previous history of strumous disease.

*Remarks.*—This was a very obscure case from the beginning of the sickness and diarrhoea. It could not possibly be connected with the accident. He had only a slight pain below the left Poupart's ligament during the first night after injury. His bowels were quite regular, no sickness, and could pass his urine during the twelve days he was in the hospital. One is bound to believe that his intestinal trouble

was due to some irritant, possibly the cakes, as he had only taken them six hours when sickness and diarrhoea set in. It is remarkable in this that severe diarrhoea should precede the strangulation.

Nulla enim est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.* lib. iv. Proœmium.

### ST. THOMAS'S HOSPITAL.

SOME CASES IN WHICH OVARIOTOMY WAS PERFORMED.

(Under the care of Mr. SYDNEY JONES.)

CASE 1. *Unilocular Cyst of Left Ovary; Recovery.*—H. M'C—, aged twenty-five, single. During the last twelve months has lost flesh; six months ago was told by her friends that she was getting stouter, but until two months since did not notice anything herself; she then noticed a swelling chiefly on the left side of abdomen, and a fortnight later had severe cramping pain, not accompanied by vomiting, which lasted three days. Catamenia regular; rather profuse. On admission a very large ovarian tumour completely filled up abdominal cavity, apparently unilocular. Eleven days after admission ovariectomy was performed under antiseptic precautions. One adhesion of recent origin was found, and the cyst, which proved to be unilocular and connected with left ovary, was removed, the pedicle having been secured with silk ligature. A suppository containing half a grain of morphia was given immediately after the operation, and the patient had a good night, being only disturbed by occasional vomiting consequent on the ether. Next day still some vomiting and much flatulence, also pain in region of left clavicle. Pulse 124. Third day: Vomited greenish fluid at intervals. Pulse 120. Allowed iced milk and soda water. Temperature at 4 P.M., 101.6°. Hypodermic injection of a quarter of a grain of morphia given six times during the day, also a dose of medicine containing seven minims of sedative solution of opium. Fifth day: The opium, which had been given on the fourth day, was discontinued. Still suffers from flatulence. Pulse 88; temperature last night 102°, this morning 98.8°. Sixth day: Allowed four ounces of wine, extract of meat, chicken jelly, and barley water. Wound dressed, and deep stitches removed, the parts being supported and approximated by broad strips of strapping. No discharge. Seventh day: Simple enema given. Ninth day: Urine contained albumen and a few blood corpuscles. After the fifth day the temperature did not rise above 99.6°, and the patient rapidly recovered, was allowed to get up on the sixteenth day, and left cured on the twenty-sixth day after operation.

CASE 2. *Tumour of Right Broad Ligament; Recovery.*—E. E.—, aged thirty, married; one child, aged eleven. Catamenia regular; noticed a swelling on right side of abdomen about ten months ago, this gradually enlarged without pain; large ovarian tumour projecting more to right side of abdomen. Four days after admission antiseptic ovariectomy was performed, adhesions extensive and numerous, the tumour first emptied of its fluid contents (twelve pints, claret colour), and then gradually separated from the abdominal wall in front and intestines behind, most of the adhesions, which were firm, being divided between a double ligature; the sac appeared to be enclosed in a fibrous capsule, and was found to have been developed in the right broad ligament, the left ovary was free. A morphia suppository was administered after the operation, but she became very restless later in the day, and had a subcutaneous injection of a quarter of a grain of morphia. Vomited three times during the day, and twice during the following night; urine drawn off by means of catheter. Next day urine drawn off every eight hours; pulse 142; two injections of morphia given. Catamenia came on; no vomiting. For some days she was troubled by a cough, which was relieved by ipecacuanha wine and bromide of potassium. The wound was dressed on the eighth, eleventh,

and fourteenth days after the operation, on the second occasion there was slight discharge, but wound looking well, and almost healed. The temperature, which on the third day was  $102^{\circ}2'$  (mid-day), did not fall below  $100^{\circ}$  until the ninth day after operation, when it fell to  $99^{\circ}2'$ ; after that it varied from  $99^{\circ}4'$  A.M. to  $102^{\circ}4'$  P.M. on the twenty-fourth day, when a swelling which had been gradually forming in the right side of abdomen, above Poupart's ligament, was aspirated, and seventeen drachms of offensive pus removed. The following evening the temperature rose to  $102^{\circ}6'$ , but there was no re-collection of the fluid, and patient left the hospital cured fifty-four days after the operation.

**CASE 3. Multilocular Cyst of Left Ovary; Recovery.**—J. S—, aged thirty-two, married, six children, youngest twenty months old. For six or seven months gradual enlargement of abdomen, and an attack of pain four months ago. She was tapped nine days before admission, and over five pints of thick viscid fluid withdrawn. Much distension of abdomen; distinct very movable tumour, chiefly on the left, with large smooth nodules on surface; indistinct thrill, and evidences of fluid in peritoneal cavity. Antiseptic ovariectomy was performed. On opening the abdominal cavity, a quantity of fluid, similar to that withdrawn fourteen days before, escaped. A multilocular cyst, connected with the left ovary, was removed after ligature of pedicle in two parts, and previous separation of slight adhesions. The large smooth nodules were found to be very tense cysts, which had perforated the wall of the large one and allowed of the escape of fluid into the abdominal cavity. Next day she complained of slight pain in the abdomen and thirst, had slept well, and only vomited three times. Temperature in the morning was  $99^{\circ}$ ; pulse 96. In the evening, temperature  $101^{\circ}$ ; pulse 100. For the first six days urine was drawn off by catheter every eight hours, and the patient allowed only fluids. On the fourth day the temperature had gradually fallen to normal, and continued so afterwards. Bowels opened by enema on the seventh day; wound dressed on the eighth, and deep stitches removed, the abdomen being supported by strapping. Without any further symptoms, she left cured forty-one days after operation.

**CASE 4. Solid Tumour of the Right Ovary; Recovery.**—S. K—, aged twenty-five, married, three children, noticed a small lump, the size of an egg, three years ago on the right side, after the birth of her first child. When first admitted she was suffering from peritonitis and anæmia. She was in hospital fifty-five days, and left cured. She came in again five days afterwards suffering from peritonitis, which had commenced the previous night; the attack was acute and lasted seven days. A rounded tumour was found in the lower abdomen, not connected with the uterus. Eleven days after admission antiseptic ovariectomy was carried out, and a solid tumour connected with the right ovary removed. After the adhesions in front had been peeled off, and some fresh ones divided between a double ligature, there were some still more recent ones on the upper and right side. The left ovary was healthy. The surface of the tumour was of a yellowish hue and suggested inflammatory softening. She had four injections of morphia during the night, from one-third to one-fourth of a grain, and slept for five hours. Next day the temperature was  $100^{\circ}4'$ , and the pulse was 140. She had no vomiting. The urine was drawn off by catheter for six days. The wound was dressed on the seventh day, when it had firmly united, and the sutures were removed and the parts supported by strapping. There was no further rise of temperature, and the patient left the hospital thirty-five days after the operation, having had no bad symptoms.

**CASE 5. Multilocular Cyst of both Ovaries; Recovery.**—C. S—, aged forty-seven, married; three children. Two years ago noticed a swelling above her left groin, which gradually increased in size. Has been tapped twice, seven and a half pints and twenty four pints having been removed. Great abdominal distension; no tumour could be defined, but pressure below umbilicus seemed to displace fluid, and a nodular mass could be felt indistinctly; there were evidences of fluid in peritoneal cavity, and patient suffered somewhat from incontinence of urine. When antiseptic ovariectomy was performed, a quantity of dark-coloured fluid, measuring fifteen pints, escaped from abdominal cavity. A multilocular cyst connected with the left ovary was removed after separation of firm pelvic adhesions; one cyst was much larger than the others and contained a ruddy-brown grumous fluid. A second tumour, also multilocular, but smaller, was removed from the right side after separation of some firm adhesions. Each

tumour was covered with a number of papillomatous nodules. A number of hard, firm, pea-like bodies were scattered over peritoneal surface of abdominal wall. Was weak and collapsed after operation, and an enema with one ounce of brandy was given; five hours after operation half a grain suppository of morphia was used, and six hours later a quarter of a grain was administered subcutaneously; she slept four hours. The temperature, which fell to  $95^{\circ}6'$ , rose to  $100^{\circ}1'$  at ten P.M., but became normal next day, and continued so throughout. On the third and fourth days bowels acted, motions loose. For two or three days she complained of pain in abdomen, and suffered from flatulence. Wound was dressed on eighth day, deep stitches removed, and parts supported by broad strips of plaster; it had quite healed, and there was no discharge. From this time she made an uninterrupted recovery, and left thirty-six days after operation.

**CASE 6. Tumour of Left Ovary; Recovery.**—E. B—, aged thirty, married, no children. Six or seven months ago had pain, and first noticed a swelling in the lower part of the abdomen; this gradually increased in size, and pain continued until about three weeks ago, when it ceased and did not recur. Menstruating every fortnight; always regular before appearance of swelling. Firm, tense, elastic tumour, smooth on the surface and with a distinct thrill of fluid on palpation, occupying chiefly the left side of abdomen, and causing considerable distension. Seven days after admission antiseptic ovariectomy was performed and the tumour removed; some slight adhesions were easily separated by the finger, but in one part a loop of intestine was firmly adherent, and the uterus also required to be separated; the pedicle, which was broad, was secured by a double ligature of silk. Next day suffered slightly from pain in abdomen and flatulence; had slept at intervals during the night, and had vomited once; two morphia injections of one-third of a grain had been given. In the evening, temperature rose to  $102^{\circ}2'$ , and continued above  $101^{\circ}$ , rising on evening of the fourth day to  $102^{\circ}6'$ , until 8 P.M. of the seventh, when it fell to  $99^{\circ}6'$ , and did not exceed it again. Was troubled only by flatulence until the fourth day, and then vomiting and hiccough came on, and she was fed by means of nutrient enemata, each containing half an ounce of brandy. Wound dressed on sixth day; a little redness about edges, but otherwise healthy; strapping applied and some of the stitches removed. Allowed to pass urine, without use of catheter; hiccough still troublesome. Fifteenth day after operation complained of abdominal pain, and vomited twice, and had much flatulence. Was better next day, and made a good recovery, leaving hospital forty-one days after operation.

### VICTORIA HOSPITAL FOR CHILDREN, CHELSEA.

WEBBED ARM, THE RESULT OF SCALD; PLASTIC OPERATION.

(Under the care of F. CHURCHILL, M.B.)

FOR the following notes we are indebted to Dr. WELDON, registrar:—

Alice B—, aged twelve, was admitted on March 21st, 1882. Two years previously she had fallen into boiling water, scalding severely the right arm and shoulder, which caused a firm cicatricial contraction of the skin and cellular tissue and muscles, so that the right arm became bound down to the chest-wall in the process of healing, forming a firm fibrous web, which, though not entirely, yet very considerably impeded the movements of the right arm, the muscles of which were a good deal atrophied from disuse. Fig. 1 represents the arm at the extreme point of tension from the side, after a drawing and tracing taken by Miss Will, the Sister of the Ward, shortly before the operation. The girl in other respects was remarkably strong and robust for her age. The primary operation was performed on March 31st, the final one on April 25th.

**Remarks by Mr. CHURCHILL.**—Carefully reviewing the past history of this case, the cause of the contraction of the tissues, and the wasting of the muscles of the upper arm, it became needful to determine the plan of operation which would best secure the permanent use of the arm with as little constraint as possible. The girl was altogether disabled from her occupation, that of domestic service. She could neither raise her arm to sweep, nor could she carry a child. By referring to the woodcuts it will be seen that the chief impediment to the liberation of the arm was a firm thick band of cicatrix tissue resembling a piece of

indiarubber, which bound the middle of the upper arm to the chest close to the right mamma. Just above this there was some fairly sound skin, which was thin, elastic, and adjustable, extending up to that which originally constituted the floor of the axilla, as evidenced by the growth of hair. In this situation was a small pouch of integument

FIG. 1.

about the size of a thimble. By stretching this pouch with the index-finger backwards, it could be brought into relation with the posterior part of the double web, which was dense and hide-like, and about four inches in depth. The first object was to form a new floor to the axilla by uniting together at the upper part these two widely separated folds

FIG. 2.

of integument, thus constituting a base of operation somewhat resembling the preliminary operation for webbed fingers. (Mr. Churchill makes a new septum between the roots of the fingers by perforation before dividing the web.) For

this purpose a large trocar and cannula were passed through the pouch, and after piercing this it was forced through the hide-like integument at the back, having its exit below the glenoid fossa of the scapula. The trocar being withdrawn a piece of elastic tube was passed through the cannula as a guide, and the cannula was then removed. To keep up the approximation of the divided edges the elastic tubing was strained by being passed through two small reels, one placed in front and the other behind. Both were fixed by a knot at the end. After ten days the tubing was cut away, and measurements were taken for clamping the remainder of the web, so as to form by a plastic operation a new arm-piece and a new chest-piece; the web to be divided vertically through the centre and the cut edges embraced by the clamps severally approximated. These clamps were designed for a double purpose—first, to arrest the hæmorrhage, and then to hold together the tissues which otherwise would have retracted and left a wide gap leading up to the axilla. Instead of the ordinary clamp with a hinge and screw, it was proposed to curve both arms of the clamp and to fix them at both ends with adjustable screws, so that the tension might be uniform throughout. As there was some delay with the instrument maker, and moreover as pus from the granulations was gravitating to the lower part of the double web, threatening cellulitis, Mr. Churchill proceeded to extemporise a pair of clamps with stiff wire bent upon itself and the ends tied together; one clamp being on the arm side of the web and the other towards the chest. Harelip pins were then passed through the web, close to and parallel with the clamps, and the double flap of integument was divided up to the sinus which formed the new floor to the axilla, and which was found to be granulating over nicely. The cut edges were drawn together and the harelip pins fixed with silk, in the usual way.

As might be expected, some of the cicatrix tissue sloughed, but on the whole the wounds healed very rapidly, and the girl went out with her arm quite liberated from her side twenty-six days after the operation. Fig. 2, taken by tracing from a photograph, shows how she could on July 1st raise the arm to the same height as the other, without any straining or stiffness of joint or muscles. It will, of course, require constant use and some gymnastic exercise in order to develop the deltoid and scapular muscles, which have become wasted by disuse for so many months.

#### QUEEN'S HOSPITAL, BIRMINGHAM.

SUICIDAL PISTOL WOUND OF PERICARDIUM, HEART, AND STOMACH; DEATH IN TWENTY-THREE HOURS.

(Under the care of Mr. WEST.)

E. E—, a bank manager, was admitted April 20th, 1892, at 7 P.M., with a circular gunshot wound on the left side of the chest one-third of an inch in diameter, three inches below the nipple, and one inch to its sternal side. Patient suffered from slight shock, but was quite sensible, and remained so till he died. There was no external hæmorrhage, and only slight traces of blood on his shirt. He twice vomited after a pint of blood. Death occurred about 6 P.M. next day, nearly twenty-four hours after the infliction of the injury.

*Necropsy.*—A wound existed over the fifth intercostal interspace, with blackened inverted margin. The course of the bullet was as follows:—Through the fifth interspace into the pericardium, lacerating a few fibres of the apex of heart over the posterior interventricular sulcus, emerging from the pericardium close to the wound of entry, it passed through the diaphragm into the stomach at its cardiac end, through the cavity and out again by its posterior surface. It then passed again through the diaphragm into the posterior mediastinum, and lodged in the body of the tenth dorsal vertebra about half an inch to the left of the median line. Heart healthy. Lungs healthy and uninjured by bullet. Right pleura natural; left pleura contained a large quantity of bloody fluid. Liver cirrhotic. Kidneys slightly granular. Intestines full of black blood; abdominal aorta extensively atheromatous. Spleen soft and friable.

The rarity of wounds of the heart, pericardium, and stomach, and the fact that the man lived nearly twenty-four hours after so serious a complication of lesions of important organs, will, perhaps, be deemed a justification for this case being recorded.

## Reviews and Notices of Books.

*Catalogue of the Pathological Museum, Medical College, Calcutta.* By J. F. P. MCCONNELL, M.B. Calcutta: Printed at the Bengal Secretariat Press. 1881.

A GOOD catalogue is a necessary adjunct to every museum, and the thanks of all workers in the subject which the collection illustrates are due to him who undertakes the laborious task of its compilation. In the present instance the author has been engaged on the work for several years, and has succeeded in producing a catalogue which for skillful arrangement and careful description is admirable of its kind. Glancing through the pages of this handsome volume, one is struck by the systematic manner in which the work is planned and also by the terse but explicit paragraphs in which the specimens are severally described. The author has thus enabled those of us who have no personal acquaintance with the collection to judge of its quality and, indeed, to marvel at its very complete character. The Calcutta Museum contains, we may venture to say, many specimens the like of which are not to be found anywhere else in the world. It is, of course, rich in specimens of diseased conditions peculiar to tropical climates; but it also abounds in well-marked instances of the results of injury and disease which are common to all regions. The whole collection, numbering nearly 3000 specimens, has been subdivided into twenty series, commencing with fractures and dislocations, then diseases of bones, diseases of joints, injuries and diseases of muscles, diseases of the spine, and, in turn, the injuries and diseases of each several system of organs. Then come tumours (a very complete collection, well arranged), malformations, &c., entozoa, and calculi. In an appendix is contained a catalogue of the casts, wax models, and drawings belonging to the Museum.

The first catalogue of this valuable collection was made in 1865 by Dr. Jos. Ewart. Since then, thanks to the contributions of medical officers in all parts of the country, the specimens have nearly trebled in number. Selecting some almost at haphazard, we may mention specimens of syphilitic hypertrophy of the skull, those of rupture of the heart (a considerable number), of aneurism of the heart, of aneurism generally (a complete series), of nerves in leprosy, intestines in dysentery, and abscess of the liver; some specimens of mycetoma or madura foot; and among parasites, specimens of amphistoma and of the *dochmius duodenalis*. The collection of urinary calculi is a special feature of the Museum.

The art of catalogue-making requires special attributes, and demands much assiduity and a wide knowledge of the subject. Mr. McConnell has shown himself particularly suited for the work, and the result is a catalogue which is a thorough guide to the Museum. The very full index at the close of the book adds much to its value and utility.

*De la Lithotritie Rapide.* Par le Dr. RELIQUET, Lauréat de l'Institut, Vice-Président de la Société de Médecine de Paris, &c. Paris: Adrien Delahaye. 1882.

DR. RELIQUET is the author of several treatises, small and great, on the diseases of, and operations on, the urinary organs, but he had not hitherto written on the new form of lithotrity introduced by Bigelow. Nor, indeed, can we say that he has now done so. In the paper before us Bigelow's original lithotrite and evacuator are figured and described, but his recent improvements of them are not so much as mentioned, and it does not appear that Dr. Reliquet has tried either of them. In this and other points it bears marks familiar to us in a good deal of the current French medical literature; the author is eminently theoretical, and deems it not improper to discuss instruments and methods of the value of which he has not had personal experience.

The main points dwelt upon by Dr. Reliquet are these: First, the necessity of so placing the patient that the lithotrite at once seizes the stone on entering the bladder; or, in other words, having the lowest part of that viscus in a line with the axis of the membranous and prostatic portions of the urethra. Pointing out that the position necessary for this varies with the shape of the bladder, he urges the necessity of trying before the operation what position secures this object. He himself uses a special apparatus, which, placed on the bed under the patient's buttocks, can be used to raise the pelvis to any desired height, and to rotate it laterally. He then describes his own form of lithotrite—*brise-pierre à pignon*—the special features of which are a female blade fenestrated in its whole length, with three small wedges of steel projecting from either side into the fenestrum; a male blade, with wedge-like projections, serrated on their fine edge, which can not only be driven into, but actually made to project beyond the female blade. It is used with a mallet or a rack and pinion. It is claimed for this instrument that it cannot possibly become clogged with debris, that it has not to be withdrawn from the bladder until all the crushing is complete, and that the portion of calculus caught between the two blades is completely ground up between their wedges. With this instrument it is alleged that stones of two to two and a half centimetres in diameter can be crushed completely in from one to three minutes. In cases where the bladder possesses contractile power Dr. Reliquet is opposed to "aspiration" to extract the fragments, but prefers to rely solely upon repeated injections of fluid through a full-sized catheter with a double large eye. Where, however, the expulsive power of the bladder is deficient, he uses an aspirator, and prefers Thompson's model to Bigelow's. Thus he assents in the main to Bigelow's propositions, and advocates crushing the stone at once, and removing all the fragments by artificial means, as the safest mode of emptying the bladder of a calculus. That his instrument will be preferred to those in use in this country and America we cannot anticipate. It is to be urged, however, in support of his preference for evacuation of fragments by the contractile power of the bladder rather than by aspiration, that it causes less disturbance of the bladder itself, but on the other hand it is less powerful and slower. It may be worth a trial, however, in cases of phosphatic calculi where the fragments are very light. Further, Dr. Reliquet recommends an injection of weak carbolic lotion at the end of the evacuation, to be followed by injection of boracic acid solution to be left in the bladder, but neither of these suggestions is novel.

*Sarcoma and Carcinoma; their Pathology, Diagnosis, and Treatment.* By HENRY TRENTHAM BUTLIN, F.R.C.S., Assistant-Surgeon and Demonstrator of Surgery, and of Diseases of the Throat, St. Bartholomew's Hospital; lately Erasmus Wilson Professor of Pathology, Royal College of Surgeons. With four lithograph plates. London: J. and A. Churchill. 1882.

MR. BUTLIN's lectures at the College of Surgeons in the years 1880 to 1881 were published in full in our columns at the time. The volume before us is to a large extent a reprint of those lectures, but the tables of cases have been enriched by a few additions, and the subjects of diagnosis and treatment, which were not touched upon in the lectures, are discussed more or less fully in the volume before us. The chief feature of the work is the care that has been taken to have the data as satisfactory as possible: the cases utilised have all been submitted to microscopical investigation, and the structure of the new growths in every instance has been ascertained with precision. This accounts for the limited number of cases to be found in the tables; but it gives to Mr. Butlin's work a value that would be

unattainable by any other means. The connective tissue or epithelial origin of a tumour is the test upon which Mr. Butlin relies to distinguish a sarcoma from a carcinoma. His classification of the species of these two great families of malignant tumours is simple, and at the same time satisfactory; its chief peculiarity is that it groups scirrhus and encephaloid cancer together as spheroidal, or glandular-celled carcinomas. The tumours of each bone are considered separately, and a broad line of distinction is drawn between those starting under the periosteum and those having a central origin. Mr. Butlin shows that this distinction has more than a mere pathological interest, for his cases prove that central sarcomata are less malignant than the subperiosteal. The testicle, tongue, œsophagus, and tonsil are the other organs whose malignant tumours are discussed. The plates, drawn by Mr. Butlin himself, are a great addition to the text, for they are faithful representations of the actual appearances, and will prove of great service to those who are not familiar with morbid histology.

## Analytical Records.

### AERATED CLARET-AND-LEMONADE.

(J. PROSSER & Co., BURY-STREET, ST. MARY AXE.)

CLARET-AND-LEMONADE has of late years become deservedly popular. No more wholesome or pleasant summer drink could be devised. The idea of uniting the two ingredients in the same bottle is a good one, and the product will be welcome at picnics and in yachts, as well as in private houses.

### EMBLIC MYROBOLANS.

(WM. MARTINDALE, NEW CAVENDISH-STREET.)

The fruit of the Indian *Phyllanthus emblica* preserved in syrup. It is said to be a mild diuretic and purgative, and a pleasant confection. We cannot honestly endorse the latter description. The fruit, though not exactly "nasty," is dry and somewhat harsh.

### ESSENCE OF MALT, PREPARED BY DENCE AND MASON'S PATENT PROCESS.

(BRAND & Co., MAYFAIR.)

As might have been expected from Messrs. Brand and Co.'s high reputation, this is an excellent and trustworthy malt extract. The essential condition of evaporation at a low temperature, so as to avoid alteration of the diastase, has evidently been attained.

### CONCENTRATED WATERS.

(ROBINSON, RICHMOND-STREET, PENDLETON, MANCHESTER.)

Among the samples sent to us, we find Aq. Anethi, Anisi, Cinnam. ver., Rosæ, and some dozen of others. Diluted with forty parts of water they form the ordinary waters of the Pharmacopœia. They are excellent in quality, and will be very useful, especially in country practice.

### SOAP LEAVES.

(WILLERINGHAUS, KLINKER, & Co., 13, HAMSELL-STREET.)

We have received samples of a newly patented invention that promises to be of some service, especially to members of our profession. It consists of small thin soap tablets, arranged in the form of leaves in a book. Each leaf suffices to make a good lather, and the convenience as well as portability of the article are great recommendations in its favour. The makers are Messrs. Reithoffer and Neffe, of Vienna, to whom the above-named firm are the London agents.

## THE GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

TUESDAY, JULY 4TH.

DR. ACLAND, PRESIDENT, IN THE CHAIR.

THE Council considered the case of John Wise Wilson, who had been convicted and sentenced to fourteen days' imprisonment for being found wandering about without visible means of subsistence. There being not sufficient evidence of identification, the Council did not direct the name to be removed from the Register.

The Council then took into consideration the case of David Beatson Murdoch, who was summoned to attend to answer a charge of "infamous conduct in a professional respect."

Mr. FARRER, the solicitor of the Council, explained that there were three imputations against Mr. Murdoch. The first was that of employing unqualified practitioners to attend patients at various dispensaries, and also at their own houses; the second was a charge of allowing an unqualified practitioner to sign his name to a false certificate of death; and the third was that in cases in which unqualified practitioners attended he himself appeared at the last moment and signed certificates of death so that it should appear that the patients had been attended by a qualified practitioner. With reference to the last charge there was no sufficient evidence of continued practice to support it. As to the charge of signing a false certificate, Mr. Murdoch himself alleged that Mr. Griffin, the unqualified practitioner who signed his name, did not sign it by his authority, and that the signature was a forgery; and there was no evidence to support the allegation that Mr. Griffin had authority to affix the signature. The evidence with regard to the first charge, that of employing unqualified practitioners in dispensaries, was in the depositions taken at a coroner's inquest, coupled with his own written statement to the Council.

Mr. FARRER then read the evidence at the inquest on Martha Elizabeth Bailey Chatfield on the 7th of July last, and the statement that "Mr. Murdoch is seriously to blame in allowing Colonel Griffin to practise in his name, and that the deceased was unsatisfactorily treated by his dispensary attendant."

Before Mr. Murdoch was called in,

Dr. HAUGHTON called attention to the serious aspect of the case, and to the remark of the Home Secretary with reference to it in Parliament, to the effect that the proper course was to bring it before the attention of the Medical Council with a view of putting the Act into force against the offender. It should be regarded, he said, as a typical case of a most serious character, and it demanded the most serious consideration of the Council.

Mr. MURDOCH was then called in, and stated, in answer to questions by Mr. Farrer and several members of the Council, that he was the owner of the dispensaries at 149, St. Leonard's-road; at 37, Ben Jonson's-road; at 135, East India-road; and at 165, Kingsland-road; and he had a qualified practitioner at East India-road, but not at the other dispensaries. His own residence was at 200, Dalston-lane. He had attended the inquest, and heard the evidence of the witnesses. Asked whether he had any statement to make in reply to the charge brought against him, Mr. MURDOCH said he desired to express his sorrow for what had happened, and to assure the Council that they would have no cause to complain of his conduct in the future. He had never authorised Mr. Griffin, or anyone else, to sign his name to certificates. He was very sorry for having employed unqualified assistants. He had already closed one dispensary, and he intended to dismiss his unqualified assistants, and not employ them any more. A great deal of what Mr. Griffin said at the inquest was untrue. It was not true that he had ordered the issue of handbills announcing the reopening of the dispensary at 149, St. Leonard's-road,

Poplar, conducted by physicians and surgeons. The bills were issued by Mr. Griffin. He (Mr. Murdoch) had issued a bill with reference to another dispensary, stating that it was "conducted for the public benefit by David Beatson Murdoch, assisted by other medical attendants." By "other medical attendants" he meant his qualified assistant (Mr. W. A. Hope) and Mr. Griffin, who had informed him that he had a Canadian diploma. He had never asked Griffin to show him the diploma, and had never suspected him till after the inquest, when he told him that he had been deceiving him. He (Mr. Murdoch) could produce satisfactory evidence as to character from medical men and others, but he was not then prepared with it. The handbill stating that his dispensary was conducted for the public benefit by David Beatson Murdoch and other medical attendants was intended to be an answer to a libel that had been previously issued. He had used the term "provident dispensary," but it was not strictly so. The patients paid 2s. 6d. a week for attendance at their homes, and 1s. a week for attendance at the dispensary. The attendant visited the patients as often as necessary, according to the nature of the case. He wrote the prescriptions, and a dispenser made them up. His attention had not been called by Griffin to the case of the child Martha Chatfield. The number of out-door patients visited was about ten daily, and about twenty at the dispensary. The statement that there were as many as seventy-eight patients in a day was untrue. No list of patients was kept. There was a book showing the names, ages, and amounts paid by the patients. The 1s. and 2s. 6d. covered the cost of medicines. There was only one dispenser, and he was at St. Leonard's-road. The assistants at the other dispensaries made up their own mixtures. He (Mr. Murdoch) attended about an hour daily at each dispensary. The worst cases were kept for him to see. He trusted to the assistants to call his attention to them; he had no check upon them. The dispenser was not a qualified person. He had a knowledge of drugs, and was on the Dental Register. Mr. Hope began to be his assistant in November last. The two most distant dispensaries were about a mile and a half apart. The words in his handbill stating that the author of the libel was a "liar" were used with his (Mr. Murdoch's) sanction. The "hospital doctor" referred to in one of the depositions was a hospital student named Elliott, of St. Bartholomew's. He knew nothing of the "young lady" referred to as being kept at the dispensary; that was an affair of Mr. Griffin's. The house in St. Leonard's-road was leased to Mr. Griffin at a rent of £40, and he (Mr. Murdoch) rented the ground-floor, for which he paid 10s. a week. He had bought the dispensary of Mr. Griffin for £120, of which he had paid £50. It was kept by Dr. Shackleton before Griffin had it. He (Mr. Murdoch) was now making an arrangement with the landlord to take the whole house, with a view of carrying on the dispensary at least for a short time. He had never had anything to do with dispensaries till the last few weeks, having always been engaged in private practice.

Mr. FARRER then read the depositions of the witnesses at the inquest on Henry Arthur Parker, at which a similar finding was given by the jury.

Mr. MURDOCH said the certificate of death was not in his writing, and he had given no authority to Griffin to sign for him. The "dark gentleman" who saw the child was Griffin, and the "fair gentleman" himself (Mr. Murdoch). He had never signed any blank forms for certificates.

The Council then deliberated on the case for three hours in private. On the readmission of the public,

The PRESIDENT, addressing Mr. Murdoch, said: The General Medical Council has deliberated with the greatest care upon the case of yours that has been submitted to them. They have heard and read all the depositions, and the inquiries which were presented to them. They were read in your presence, and they heard all you had to say or wished to communicate to them. This is the decision at which the Council has arrived: "That, acting under the 29th Section of the Medical Act, the General Medical Council, after due inquiry, adjudges that you have been guilty of infamous conduct in a professional respect; but the Council does not now direct the Registrar to erase your name from the Register." They have come to the conclusion, after the fullest consideration, being compelled to form a distinct conclusion on the point submitted to them under Clause 29 of the Act; and they have not desired or intended to remove your name from the Register, believing that you have undertaken to discontinue the various acts which have been com-

plained of in the allegations presented to them. That is the decision of the Council.

Mr. MURDOCH: I am much obliged to you, gentlemen, for the lenient view that you have taken of my case. I can assure you that I will endeavour in future to abide by the strict rules of the Council.

WEDNESDAY, JULY 5TH.

Sir WM. GULL gave notice of the following motion: "That for the putting into action Section 29 of the Medical Act, three-fourths of the votes of the whole Council must be in the affirmative."

The Council proceeded to take into consideration the communications with regard to Mr. Dixon of South Australia.

Mr. MACNAMARA said that every fact connected with the case was now before the Council, and it was clear that the attendance required by the Council had not been enforced. He simply called attention to the matter, and would make no motion till the answer of the representative of the Apothecaries' Hall had been heard.

Mr. COLLINS said that the communication from the South Australian Branch of the British Medical Association contained two serious accusations against the Apothecaries' Hall of Ireland. One was that of carelessness and the second that of informality. As one of the four members of the court of the Apothecaries' Hall who examined Mr. Dixon's papers and took part in his examination, he could assure the Council that there was no ground for the charge of carelessness, and he never recollected any case that came before them that received more deliberation. Mr. Dixon commenced his professional studies three years before the Medical Council came into existence, and therefore the Apothecaries' Hall considered that the responsibility of acceding to or rejecting his memorial rested upon them. Mr. Dixon stated that having lived for twenty years in the warm climate of Australia his health was so greatly injured by his residence for six months during the previous winter in Scotland, that under no circumstances could he endure a second winter in the north of Europe, as he was threatened with pulmonary disease, and would be absolutely obliged to leave before the winter commenced. With regard to the charge of informality, the court of the Apothecaries' Hall certainly departed from their own curriculum of 1855 and from the educational rules laid down by the Medical Council. Mr. Dixon did not pass the preliminary examination; did not serve any apprenticeship to a licensed apothecary; and did not go through the entire course of education; but the court regarded it as a special case, similar to one which arose twelve or fifteen years previous to the time when Mr. Dixon commenced his education, and when they were called upon by Her Majesty's Government to admit to their examination a considerable number of gentlemen practising in the north of Ireland. Those gentlemen were chiefly retired naval surgeons; they took upon themselves not only to compound medicine for their own patients, but to open shops for the sale of drugs. The licentiates of the Apothecaries' Hall required the court either to insist upon those gentlemen ceasing to violate the law or else to put the law in operation against them. The persons complained of memorialised the Government, and the Government sent an official communication to the Hall, informing them that by the 22nd and 23rd Section of their Act they were authorised to examine the candidates simply and solely upon their knowledge and competency. The opinion of some of the highest legal authorities in Ireland was obtained, and they all agreed that the 22nd clause gave the Hall very considerable liberty of action. Virtually it enabled them to grant licences *sine curricula*, but they had endeavoured at all times and under all circumstances as far as possible to conform their regulations and conduct to the desires of the Medical Council. In the case of Mr. Dixon, they considered that justice to an individual was consistent with the public good, and that they were doing what was fair and right by admitting him to an examination, and, on his passing it satisfactorily, giving him the licence of the Hall to practise as a general practitioner. Under these circumstances he proposed "that having considered the communication from certain members of the South Australian Branch of the British Medical Association, with regard to the case of Mr. Hartley Dixon, and the reply of the Apothecaries' Hall of Ireland thereto, and having now heard a further statement on the subject from the representative of the Apothecaries' Hall of Ireland, the Council is of opinion that it is unnecessary to take further steps in the matter." If they had acted in an informal

manner in this case they had only done what they were obliged to do, in accordance with the direction of the Government on a previous occasion.

Mr. MACNAMARA seconded the motion. He said he thought it only right to inform the Council that no mercenary motives could have influenced the governor and Company of the Apothecaries' Hall, for the fee did not cover the expenses of the examination.

The resolution was agreed to.

The Council then proceeded to consider the petition of Mr. George Stratten Symmons, for the restoration of his name to the Medical Register.

Dr. CHAMBERS moved that the name be restored to the Register.

Dr. PITMAN said the Council had no power to restore the name in such a case unless the person obtained from one of the bodies another qualification, or the renewal of his former qualification; but in accordance with the desire of the Council all the bodies had agreed not to give such a qualification.

Mr. TURNER said that the petitioner appeared to have had two qualifications: membership of the College of Surgeons, England, and the licence of the Apothecaries' Society. He only asked for the restoration of the latter, from which it might be suspected that he had not been struck off the roll of that Company. If, therefore, he presented his licence could the Council refuse to register him?

The PRESIDENT said it was manifest that a legal point was raised in this case, and it might be advisable to obtain legal opinion with respect to it.

After a short discussion, Dr. CHAMBERS withdrew his motion, and

Dr. PITMAN moved, and Dr. CHAMBERS seconded, "That the opinion of counsel be taken as to whether the Council has power to restore to the Medical Register the name of a person erased under Section 29 of the Medical Act."

The resolution was agreed to.

The next subject taken into consideration was that of Wm. Story of Linsdale, Bedfordshire, who had been sentenced to five years' penal servitude for setting fire to his house "with intent to injure and defraud." The Royal College of Surgeons of England had removed his name from the list of Fellows and Members.

Mr. SIMON said he should have no hesitation in voting that the name be erased from the Medical Register, if he knew that at the end of the five years the Council would have the option of restoring it. Where a man had committed a crime, and the law had given him what was deemed a proportionate punishment for his offence, he (Mr. Simon) was not sure that the Council ought, in addition, to take from him the means of earning his livelihood when he was released. Undoubtedly the name ought to be struck off while the period of imprisonment lasted, but it would be better to reserve a decision upon the case till counsel's opinion had been obtained in the previous case.

On the question being put from the chair it was resolved, by eight votes to five, "That the Council direct the Registrar to erase from the Register the name of Wm. Story."

The next matter for consideration was that of Dr. Hoar, respecting whom a letter was read from the Registrar of the Divorce Court, stating that a jury had found that he had committed adultery with Mrs. Stenning. The record had been obtained by the direction of the English Branch Council.

Dr. QUAIN said that the case could only be gone into as one of infamous conduct in a professional respect, and must be dealt with in the regular way. It was, therefore, a waste of time to talk about it now. Dr. Hoar must be summoned before the Council, and tried by them.

Dr. HAUGHTON moved, "That the case of Wm. Hoar be left for the present in the hands of the English Branch Council."

Mr. MACNAMARA seconded the motion, which was agreed to.

#### DENTAL BUSINESS.

Dr. QUAIN gave a short historical outline of the proceedings of the Council with regard to the Dental Register, and referred to the various opinions of counsels which had been obtained in regard to it.

Mr. FARRER (the solicitor of the Council) referred to the opinions that had been obtained from Sir John Holker, Mr. Bowen, Mr. Vaughan Hawkins, Mr. Fitzgerald, and Sir Farrer Herschell.

Dr. STORREAR moved, "That the opinions of Mr. Bowen,

Mr. Fitzgerald, the Solicitor-General, and Sir John Holker, in regard to the registration of dentists under the Dentists Act, 1878, be entered in the General Council's minutes." He considered that in order to enable the Council to arrive at a proper decision, the opinions of counsel should be placed upon the minutes.

Dr. PYLE seconded the motion.

A long discussion ensued as to the practice in such cases, and the advisability of making counsel's opinions public.

Ultimately Sir Wm. GULL moved, "That the opinion of counsel, for the guidance of this Council for the registration of dentists, be considered confidential, and be not entered in the Council's minutes."

Dr. LYONS seconded the amendment, which was carried—15 voting in its favour and 6 against.

The Council then entered upon a prolonged discussion on the question of the erasure of certain names from the Dental Register, and it was finally agreed, "That the Council are not prepared to take steps, as suggested by the Dental Association, to erase names from the Register which have been placed therein by the Council under legal advice."

A motion by Dr. PITMAN, seconded by Mr. TEALE, to suspend the standing orders, and "That the Council meet at twelve o'clock to-morrow," was negatived.

The Council then adjourned.

#### THURSDAY, JULY 6TH.

#### VISITATION OF EXAMINATIONS.

After some formal business, the Council proceeded to consider the report of the Committee of the whole Council on the conclusions of the visitors of examinations, 1881 and 1882.

On the motion of Mr. TEALE, the first seven recommendations in the report were adopted by the Council. Clause 8, with reference to the limitation of time in oral examinations, and Clause 9, with reference to hygiene and preventive medicine, were not adopted; but it was resolved that the attention of the medical corporations be directed to them, and also to the subject of mental disease, which had not been mentioned in the report of the Committee of Council.

Mr. TEALE then moved, "That a copy of the visitors' report, the remarks thereon, and the resolutions of the Council be transmitted to such teachers in the medical schools of the United Kingdom as the Executive Committee might select, inviting their opinions on the subjects of medical education referred to in the reports."

Dr. QUAIN asked what was the object of inviting the opinions of the teachers. If it was intended to reopen the subject it would be a monstrous waste of time.

Dr. WATSON said that no further inquiry was needed; the work was done, and there was no necessity for communicating with the teachers on the subject.

Dr. HUMPHRY suggested that the documents should be forwarded to the medical schools without asking their opinions.

Mr. TEALE assented to that suggestion, and his resolution was passed accordingly.

#### REMOVAL OF NAMES FROM THE REGISTER.

Dr. PITMAN moved, pursuant to notice, "That it would be desirable that in any amendment of the Medical Acts provision be made as regards persons whose names may be struck off the Medical Register (under Section 29 of the new Act) that every such person shall *ipso facto* forfeit any medical title which he may at the time hold from any of the medical authorities, subject, however, to the further provision that any authority, if it see fit, may afterwards renew to such person the forfeited title, on condition of its not being again registrable under the Medical Acts, except with the consent of the General Medical Council." He said that the fact had come before the Executive Committee that there were cases in which names might be removed from the Register while the authorities granting the qualifications had no power to strike the names off their lists. The Executive Committee had passed a resolution upon the subject, which, he thought, did not require confirmation by the Council; but, as it dealt with certain powers and privileges of the medical authorities, it appeared to him that it was desirable that the Council should have the opportunity of knowing and confirming the view which the Executive Committee took in the matter. When a person was struck off the Medical Register it was within the power of some of

the bodies to erase his name from their list, but other bodies had not that power. The Council could only recommend that those bodies should not grant their qualifications again to the same person; but it was sought by the resolution that the power to grant those qualifications again should be taken from them, unless the Medical Council consented, so that the Council would have in its own hands the power of not allowing a medical body to reissue a qualification which had been forfeited to any person whose name had been erased from the Register under Clause 29. He believed there was no medical authority that did not wish to have the power of erasing names from their lists, and it was therefore proposed that in any amended Medical Act all the authorities should have such power, and that when a person's name was struck off the Register his qualification should be *ipso facto* forfeited.

Mr. SIMON seconded the motion.

Mr. TURNER said that there were bodies that undoubtedly possessed the power of striking names off their lists, but he questioned whether any university had the power to remove the name of a graduate.

Dr. HAUGHTON said that no university had such power.

Mr. CHAMBERS said that he believed the University of Oxford had exercised such a power.

Mr. TURNER said that the Scotch universities had no power to degrade a graduate. The resolution opened up a very grave question, and he thought they should have a little more light upon the legal aspects of the case before adopting it. When once a graduate's name was removed, it might be that it could not be restored without a renewal of this examination. He should like to know what the lawyers had to say upon the subject. If the motion were adopted it might throw enormous difficulties in the way of a person who desired to get his name restored on the Register, because his qualification would be actually destroyed. He would have to go through a double ordeal—that of asking the Body to renew its degree and also that of asking the Council to re-register his name. It was a question how far the Council would be justified in putting that additional difficulty in the way of the licentiate.

Dr. STORRAR said that the University of London never supposed that it could deprive a man of a degree once conferred upon him. The motion proposed to give such power of deprivation to a body quite outside the university, and such a proposal he thought would be demurred to by the university authorities. When a man's name was removed from the Register for unworthy conduct he was deprived of all the privileges of the Medical Act, and he (Dr. Storrar) was inclined to think that that was a sufficient punishment, and that it was not necessary to interfere with the universities or any of the other bodies in reference to their qualifications.

Dr. HAUGHTON sympathised with Dr. Pitman's object in bringing forward the resolution, but thought it would be impossible to carry it out. Not only had the universities no power to take away a degree once given, but Parliament itself could not take it away any more than it could unbaptise a child who had been once baptised. The university of Dublin had expended a great deal of money in endeavouring to take away the degree of D.D. from an unworthy person, but the final decision of the court was that the degree, having been once conferred, could not be taken back.

Dr. HALDANE thought it would be desirable that the motion should be postponed, as there were difficulties in the way of carrying it out, and there was no urgency in the matter, since there was no prospect of a Medical Bill being brought forward before the Council had an opportunity of meeting again. In the meantime it might be desirable to obtain information as to the legal bearings of the case.

Dr. BANKS thought that the removal of a name from the Medical Register answered all practical purposes. No doubt, however, bodies ought to possess the power of removing names if they saw fit.

Mr. MACNAMARA said that the College of Surgeons in Ireland had such a power, and suggested that those who did not possess it should adopt some means of obtaining it. The Apothecaries' Society of England had recently obtained the power by Act of Parliament. He was quite sure that the College of Surgeons in Ireland would look with a very jealous eye upon any proposal to transfer to any other body the power of removing names from the list of licentiates.

Dr. BANKS said that the King and Queen's College of Physicians, Ireland, possessed and had exercised the power.

Dr. LYONS hoped that Dr. Pitman's motion would not be

pressed to a division. The object was a good one, but, like many other desirable objects, it could not be accomplished by legislation. The power of removing names should be exercised, if at all, by each of the bodies on its own responsibility, and there was no probability of Parliament entrusting such a power to another body.

Dr. HUMPHRY did not believe that the universities would assent to their graduates being placed in any way under the authority of the Medical Council. If legislation took place upon the lines of the report of the Royal Commissioners, the several bodies and their titles would be removed further from the influence of the Council than they were at the present time.

Mr. SIMON thought that it would not be desirable to press the motion, and that Dr. Pitman's object would be answered by the discussion that had taken place. Notwithstanding Dr. Haughton's metaphor with regard to baptism, he thought that every university should have the power of striking names off its register in the case of infamous conduct.

Dr. QUAIN thought it would be sufficient to propose that, in any amended Act, all the authorities should have the power of removing names from their registers.

Dr. PITMAN said he had thought it desirable to bring the motion before the Council because the rights and privileges of universities and corporations were concerned in the question. With regard to the difficulties placed in the way of persons desiring to get their names restored, he maintained that such difficulties ought to exist. It ought not to be easy for a man to get on the Register again when once he had been struck off under Clause 29. Dr. Humphry might have spared his observations, because he was certainly in favour of the resolution when it was before the Executive Committee. Under the circumstances he was willing to withdraw the motion.

The motion was withdrawn accordingly.

#### THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

Dr. SMITH brought before the Council a correspondence between the King and Queen's College of Physicians in Ireland and the Registrar of the Branch Council for England, with reference to a licentiate of that body, Mr. O'Leary, who had been charged with malpractice by a fellow practitioner. On April 8th, 1881, a letter was written from the College to the Medical Council stating the facts of the case. At an inquest held at Birmingham Mr. R. A. Prosser, after having at a post-mortem examination examined the kidneys and abdominal viscera, swore that the kidneys were healthy, and gave it as his opinion that death was caused by negligence on the part of Mr. O'Leary, who had attended the patient but one day before her death. On that evidence Mr. O'Leary was committed for manslaughter. It was, however, subsequently shown that the kidneys had not been disturbed in their place, and that the examination of the viscera had been incomplete. That fact was disclosed before the stipendiary magistrate, and the prisoner was discharged. The grand jury also threw out the Bill at the Warwick Assizes. The King and Queen's College of Physicians desired that the Medical Council should inquire into the facts of the case, and if necessary deal with it under the powers conferred by Section 29 of the Medical Act. The Medical Council, according to standing orders, referred the matter to the English Branch Council, which body decided that the case did not seem to be one in which they could usefully take action. The College again wrote to the Medical Council directing its attention to the case. It then went before the Executive Committee of the Council, who decided that the course taken by the Branch Council for England was in conformity with the standing orders and according to the advice of the solicitor to the Council; but that under the circumstances of the case the whole subject should be thoroughly investigated. The matter again came before the Branch Council, which came to the conclusion that as there was a conflict of evidence, and as there had been no action for perjury against Mr. Prosser, it was not considered necessary to send the letter of the College, as requested, to the General Medical Council. Dr. Smith added that the College complained of the indisposition of the Branch Council to give assistance in the matter. As far as he could ascertain, the Branch Council had not taken the slightest trouble to inquire into the case so as to obtain additional information respecting it. He begged to move, "That the Branch Council be directed to make due inquiry forthwith as to the conduct of Mr. Richard Albert Shipman

Prosser, M.R.C.S. Eng. and L.S.A. Lond., in the case brought under the notice of the General Medical Council by the King and Queen's College of Physicians in Ireland in two letters dated April 8th, 1881, and May 24th, 1881; and that the Branch Council submit to the Medical Council the result of the inquiry." [At the suggestion of several members Dr. Smith modified the first part of the resolution thus: "That the Branch Council of England be requested to make further inquiry," &c.]

Mr. TURNER thought that Dr. Smith was out of order in bringing forward his motion, as the Branch Council, to whom the matter was properly referred under the standing orders, had given its decision.

Dr. LYONS said that the matter had not been brought before the Council itself, and he thought Dr. Smith was quite right in adopting the course he had pursued.

Dr. BANKS said that the King and Queen's College of Physicians had done everything it could to support the dignity of the profession, and the case it had submitted to the Council ought to be thoroughly investigated.

Sir WM. GULL said that the whole matter had been inquired into, and the Branch Council came to the conclusion that the case did not seem to be one in which it could usefully take action. There was no indisposition on the part of the members of the Branch Council to do their duty, and he complained of the imputation thrown upon them by Dr. Smith. He (Sir Wm. Gull) could judge of the kidneys without taking them out of their place.

Mr. SIMON said that the matter had been thoroughly discussed, and he should be glad if Dr. Smith would point out what kind of inquiry the Branch Council could have instituted.

Dr. LYONS said that an inquiry had been made into the circumstances of the case by the Local Government Board, and suggested that the Branch Council might have obtained a report of the inquiry. The case was one of very great hardship to Mr. O'Leary, and he (Dr. Lyons) was strongly of opinion that some action should be taken in the matter. He therefore supported Dr. Smith's motion.

Mr. MACNAMARA thought it was very much to be regretted that the Branch Council had not pursued the case farther.

Mr. SIMON suggested that if there were any depositions or other documents in the case which had not been forwarded to the Branch Council they might be sent to that body with the object of making further inquiry. As a member of the Branch Council he should cordially concur in that course being adopted.

The PRESIDENT said that Dr. Smith was in order in bringing the matter before the Council. The question, however, had been considered by the Branch Council and by the Executive Committee, whose decision had been based on the opinion of the solicitor to the Council. The motion, as originally worded, would have been a distinct vote of censure upon the Branch Council, by whom "due inquiry" had been made into the circumstances of the case; but if Mr. Simon's suggestion were adopted, no vote of censure would be implied.

Dr. SMITH and Dr. BANKS stated that they had no intention of proposing a vote of censure on the Branch Council or the Executive Committee.

After some further discussion, Dr. Smith's motion was agreed to, and the Council adjourned.

FRIDAY, JULY 7TH.

#### REGISTRATION OF MIDWIVES.

The following report was presented by the Committee on the Draft Bill for the Registration of Midwives in England and Wales.

Three meetings have been held by the committee appointed by the Council to consider and report on a Draft Bill for the Registration of Midwives in England and Wales, recently forwarded to the Registrar from the Privy Council office with a request that "the Medical Council would favour their Lordships with any remarks it might think desirable to make thereon." At the request of the chairman of the committee, Dr. Aveling and Mr. Ernest Hart attended before it, to give such information as they might wish to offer. The members of the committee were present when the Council received a deputation appointed by the Parliamentary Bills Committee of the British Medical Association, consisting of Mr. Ernest Hart (Chairman), Dr. Aveling,

Dr. Holman, Dr. Playfair, and Mr. Sibley. The committee has also referred to the record of the previous action of the Council on this question, contained in vol. xiv. of the Minutes (p. 198), and to a paper upon it by the Obstetrical Society of London, which is given on pages 51 to 54 of the Appendix to the same volume of Minutes. The committee now submits the following report, the opinions and suggestions in which are arranged under three heads—viz., (1) those which relate to the expediency of legislation on this subject, and to the chief aims of such legislation; (2) those which relate to proposals in the Draft Bill referring to the General Medical Council; and (3) those which relate to other proposals contained in the Draft Bill.

1. On the expediency of legislating on this subject, and on the chief aims of such legislation. A. That, in view of the absence of any complete and satisfactory provision for the proper training and due qualification of the women who now act as midwives amongst the poorer classes of the community in England and Wales, it is—as expressed in a resolution of the Council, agreed to on the 24th May, 1877 (Minutes, vol. xiv., p. 198, Clause 15), and communicated forthwith to the Lord President of Her Majesty's Privy Council—"desirable to provide by legislation for the following two objects: first, that means under legal sanction should be provided for giving credentials of qualification to competent midwives; and, secondly, that the lives of women in labour should, as far as practicable, be protected from the incompetent." B. That, for the attainment of these objects, the essential conditions of any legislative enactment are the due training, examinations, certification, and registration of a class of qualified midwives, subject to this further condition, that women now practising as midwives may, if certified to be of good moral character, and to possess a competent knowledge and experience, be granted certificates under the enactment and be placed upon the register. C. That, whilst all registered midwives should be entitled to certain privileges, they must also be subject to supervision and control. D. That, though agreeing with the limitation of the proposed enactment for the registration of midwives, in the first instance, to England and Wales (Sect. 2) the committee does not see any objection to the subsequent extension of legislation for a similar purpose to Scotland and Ireland. 2. On the proposals in the Draft Bill which refers to the General Medical Council. A. That the several functions and duties which, under the proposals of the Draft Bill, are assigned to the General Medical Council, might be better performed by the Branch Council; and, therefore, that in the several sections defining those duties and functions, for the words "General Medical Council," the words "Branch Council for England" be substituted. These functions and duties are as follows:—(a) The appointment of a midwifery board and its maintenance by the filling up of vacancies (Sect. 4); (b) the reception of an annual report from the midwifery board, as to money received and expended, as to the proceedings of the board, and as to any suggestions made by the board (Sect. 5); (c) the power to request or demand information from the board (Sect. 5); (d) the duty of transmitting the annual report of that board, with comments approving or disapproving it, to the Privy Council (Sect. 5); (e) the duty of receiving from the Privy Council the examination rules framed by the Midwifery Board, and giving an opinion to the Privy Council upon them; (f) that of receiving notices of and commenting on any modifications made in those rules by the Privy Council (Sect. 18); and, lastly, (g) that of giving an opinion to the Privy Council on the scheme for regulating the duties and practice of registered midwives (Sect. 28). B. That, as regards the proposition made in the Draft Bill, that any of the funds at the disposal of this Council, or of any branch Council, might be devoted to the purposes of an enactment to secure the registration of midwives, the Council is of opinion that this is undesirable, and that such portion of Sect. 34 as relates to those funds should be omitted from the Bill. 3. On other proposals contained in the Draft Bill. A. That it deserves consideration whether the objects of the proposed legislation could not be attained by equally effectual but more simple and economical means than those indicated in the Draft Bill. Thus: that the number of members on the Midwifery Board might, instead of being from seven to eleven, be five, of whom two should be general practitioners (Sect. 4). That the proposal to appoint a General Registrar (Sect. 8), and annually prepare and print a correct copy of a complete register of midwives for the whole of England and Wales (Sect. 9), should be reconsidered; whether, in fact, local registers and

local registrars would not suffice, these last-named officers (preferably some existing county or district officials, such, for example, as registrars of births, deaths, and marriages), to have charge of the registers, and to have the power of making alterations in and erasures from the registers, in consequence of change of residence, cessation from practice, or death, assigned in the Draft Bill to the proposed General Registrar (Sect. 14). *B.* That, as proposed in Sect. 9, women who have obtained a certificate of having passed an examining board, duly recognised under the enactment, should be registered in a list (A), and those who have not passed such a board in another list (B). *C.* That, as proposed in Sect. 11, persons so registered should be allowed to practise in any part of Her Majesty's dominions. *D.* That, in agreement with the principle laid down in Sect. 9, the persons described in the second part of Sect. 12, as having passed an examination before a competent board, supposing it to be duly recognised as such under the enactment, and having received a certificate from such competent board in any part of Her Majesty's dominions, as well as in any British colony or foreign country, entitling her to practise, &c., &c., may be admitted to be registered in list A, and not merely in list B, as proposed in line 19, Sect. 12. And, accordingly, that the words "in any part of Her Majesty's dominions, or" be inserted after the word "certificate" in line 14 of the section, and in line 19, the letter "A" be substituted for the letter "B." *E.* That Sect. 14 must be amended, so that the names of persons shall be removed from the local registers, as well as from the general register (if such a general register be kept), or so that they should be removed from the local registers, if only local registers be kept. *F.* That in Sect. 15, line 33, the word "twice" should be omitted; that in line 35, the words "or neglect" should be inserted after the word "conduct;" that in line 36, for the word "practice" the words "the register" should be substituted—this last change being in accordance with the terms used in Sect. 24, line 6; that, if this last change be adopted, the words "be suspended or to," at the end of line 41, be omitted, and the words "suspended or" be inserted after the word "name" in line 42; that the lines contained in a parenthesis in this section, on page 9, relating to the publication of suspensions or removals from the registers, be erased; and, lastly, that in line 14, the word "practice" be omitted. *G.* That in Sect. 18, line 16, the words "and training" might be introduced. *H.* That in Sect. 28 power should be given to the medical authorities to have an opportunity of informing themselves of, and objecting to, the rules for regulating the duties and practice of midwives, just as, according to Sect. 18, lines 25 to 29, they are to be consulted on the examination rules. *I.* That in Sect. 29, line 10, the words "as far as possible" might be omitted. *K.* That in the Form D, page 16, line 12, the word "ordinary" be struck out. *L.* The committee has further to observe that a few suggestions of verbal alterations, not involving the principles of the proposed enactment, have been made in a copy of the "Draft Bill" handed in with this report. In conclusion, the committee, whilst offering no opinion as to the appropriate time for legislating on this subject, recommend that, in the event of a Bill being brought before Parliament when the Council is not sitting, a copy of the measure, and notice of changes in it, should be submitted to the Branch Council.

July 4th, 1882.

JOHN MARSHALL, Chairman.

Mr. MARSHALL, in bringing up the report, said that the committee were very anxious that the session should not pass over without something being decided upon the subject by the Council. The question had been brought before the profession, the Government, and the Council on many occasions, and as far back as 1877 the Council took the matter into its serious consideration, mainly in consequence of the exertions of Mr. Simon. After deliberately considering the question, the committee had come to the conclusion embodied in the report, that the Council ought not to shirk the responsibility of taking some part in the proposed measure. Its responsibility would be merely that of appointing a midwifery board and receiving reports from it, the Council merely reserving to itself the power of approving or disapproving of the reports, and of reporting the board, if necessary, to the Privy Council. They were appointed to protect the public in medical matters, and if there was one medical or surgical matter that concerned the whole community, it was the safety of the women of the country. If the Council declined to accept any responsibility in such a matter, it would be a derogation from its high duties, and a shrinking

from what it might reasonably be called upon to undertake. It had been suggested that the proposed action of the Council should be permissive and not obligatory, but he thought it would be better to grapple with the subject in a bold and decided way. It involved no degradation to the Council, but it would be an honourable and creditable thing for it to do. The board appointed by the Council would have to undertake the duty of appointing local examiners, and he thought that an arrangement of that kind would be the very best to do away with local jealousies and antagonisms. He could hardly conceive a case arising in which there would be any friction in consequence of the action of the Council or the central board. If the Council declined the small amount of responsibility proposed to be given to it, it would be placing itself in a perilous position, and the Privy Council might, after all, declare that the Medical Council ought to undertake the duty from which it shrank.

Dr. HAUGHTON seconded the adoption of the report, and alluded to the importance of the question to the general public.

Mr. SIMON said the Council was much indebted to the committee for their labours and observations, but he thought they would have acted more wisely if they had contented themselves with laying down the principles on which legislation should proceed, instead of entering into a minute criticism of the clauses of what, after all, was nothing more than an amateur Bill. What had taken place with reference to the Dentists Bill promoted by Dr. Quain was enough to show the desperate mess they were likely to get into if they proceeded on the lines of a non-official Bill. He was ready to accept the first three or four resolutions of the committee, but not the subsequent proposal with regard to the functions of the Council. The committee did not appear to have realised the immense gravity of the peremptory character of the proposed measure. It had been assumed that the responsibility of the Council in regard to matters of detail would be got rid of by the appointment of a central board, but that would not be the case. The board would still be the agent of the Council, and the Council would be responsible for all that it did or omitted to do in regard to its appointment, its expenditure, and the like. He besought them, before taking any further step in the matter, to take legal advice in regard to the effect of the Bill in respect to any demand which might be made on the Council. It would not be sufficient to strike out, as proposed, the financial clause of the Bill, because if the Council were directed to do certain things or to cause them to be done, and if the funds fell short, could anyone doubt that the Council would be called upon to pay the expenses? It was possible that the board might work satisfactorily for a time, but it was possible that the board might not work satisfactorily, and in that case the work would have to be done by the Council. A similar thing might happen to the obstetrical "tiff" at the College of Surgeons, when the examiners struck and the College was left without the means of fulfilling its obligations. If there happened to be any disagreement between the Council and the proposed board, what means would the Council have of carrying on its administrative business in anything like continuity? If they could not do that they ought not to accept a legal position in which they would be called upon to undertake it. His contention was that legislation on the subject ought to be permissive only. The relation of the Council to the board should be similar to its relation to the medical examining bodies. The Council did not appoint the examiners of those bodies, but only exercised a general sanctioning power with reference to their proceedings. If the Council had to undertake the management of midwives, there would be a tremendous hypertrophy of one particular section of its work, which would grow to such a magnitude as really to prevent their doing justice to other matters. The dental business had taken up a great deal more time than was expected, and work relating to midwives would occupy still more. What was wanted was that the Council should have power to approve any scheme that might be brought forward by other associations interested in the subject. He should prefer to see the scheme promoted by one of the medical authorities, or by a combination of those bodies, and then submitted to the Council. That would be much better than the tremendous machinery proposed by the committee, which would involve the consideration of minute details that ought not to be brought under the consideration of the Council. He thought that the Council should not recommend the proposed Bill as a basis of legislation, but rather lay down certain general principles and then ask the Government to deal itself with the subject.

Sir WM. GULL supported the views expressed by Mr. Simon. There were, he said, no universities, authorities, or schools specially connected with the education of midwives, and if the Council had to take the matter under its supervision, it would be in very much the same position as it would occupy if required to legislate for the education of medical men in the absence of the existing universities and medical corporations.

Dr. QUAIN denied that he was a promoter of the Dentists Bill, and said he believed that he was the only member of the Council who in the first instance saw the terrible difficulties they were likely to get into by having anything to do with the dentists. That being the position, it was not likely he was going to ask the Council to interfere in reference to the midwives. The proposed arrangements involved no trouble or responsibility on the part of the Council. In 1877 the Council had resolved, at the instance of Mr. Simon and Sir William Gull, that legislation was desirable, but nothing more would have been done if the gentlemen who were specially interested in the question had not brought it forward. Nothing could be more simple than the Council nominating five or seven persons to undertake the necessary work. The Council would only have to receive a report of what the board had done; the ultimate responsibility would be in the Privy Council, and not in the Medical Council. If the appointment of a board were not placed in the hands of the Council, he believed there would be endless jealousies and antagonisms at work.

Mr. MARSHALL said it appeared that the Council were agreed as to Subsections A, B, and C of Clause 1 of the Committee's Report. He would therefore move the adoption of those clauses before proposing the others, on which a difference of opinion existed.

The clauses were then put and agreed to.

On the motion of Mr. MARSHALL, seconded by Dr. HAUGHTON, Subsection D, with reference to the extension of legislation to Scotland and Ireland, was adopted as a resolution of the Council.

Mr. MARSHALL proposed Section A of Clause 2 of the Report, declaring that the functions proposed to be assigned to the General Council might be better performed by the Branch Council. He hoped that the Council would not timidly hesitate and procrastinate, but would resolve that something definite should be accomplished.

Dr. HAUGHTON seconded the motion, and said there was no body in the United Kingdom competent to undertake the responsibility except the Medical Council. After full consideration, the committee was of opinion that, with the view of facilitating the working of the Act, the functions of the Council should be assigned to the English Branch Council, in whose transcendent wisdom he was quite sure they all had the greatest confidence.

Sir WM. GULL stated that in that case the Branch Council would be independent of the General Council.

Mr. TURNER said that the Branch Council only existed as part of the General Council; and there was a proposition that it should be abolished altogether. He thought it would be better to assign the proposed duties to the General Council itself, because it was that body that would be responsible.

Dr. QUAIN said it would be more economical if the work were carried out by the Branch Council. If it should cease to exist, its place would be taken by a divisional board, or some other body. If the Act of Parliament placed the duties in the hands of the Branch Council, there would be no difficulty in the matter.

Dr. WATSON said if the motion were carried and acted upon, it would establish an *imperium in imperio*, and the General Council would have no power of directing or controlling the proceedings of the Branch Council. He doubted, however, if the Legislature would assent to any such arrangement.

After some further discussion, the following resolution was adopted: "That it may be made competent to the General Medical Council to delegate to the English Branch Council any functions and duties which, under the Draft Bill, are proposed to be assigned to it, except that of making representations to the Privy Council."

Mr. MARSHALL then moved that Subsection A of Section 2 of the report, describing the functions to be assigned to the Council, be adopted as a resolution.

Dr. HAUGHTON seconded the motion.

Mr. SIMON moved, as an amendment, "That as regards the proposals made in the Draft Bill to assign

certain functions and duties to this Council, the Council is not prepared to accept the responsibility in unconditional and obligatory terms such as are used in Clause 4 of the Draft Bill; but that the Council would not object to be made, under permissive law, the sanctioning medical authority in the proposed matter, with duty in that capacity to approve or disapprove any scheme which the Obstetrical Society (or others) might bring before it for such purposes as are in question." The Council, he said, should undertake responsibilities only in proportion to what it could do. According to the committee's proposal, the Midwifery Board would be as much the agent of the Council as a secretary would be the agent of his employer. The best arrangement, he thought, would be that if at any time within the passing of the Act any college or combination of colleges, or if at any later time any voluntary society of medical practitioners, prepared a scheme and presented it to the Medical Council, the Medical Council might report it to the Privy Council, with any amendments, and the Privy Council might, if it saw fit, affirm it; and such confirmation should give it legal effect.

Sir WM. GULL seconded the amendment, and protested against legislating in undue haste.

Dr. HAUGHTON thought that Mr. Simon's suggestion was an excellent one, and if adopted would bring all Ireland under the Bill.

Mr. TURNER said that the amendment gave no guarantee that any machinery would be established; it only provided that the Council should take action if other bodies provided schemes.

Mr. SIMON said that if no outside body acted the matter would fall to the ground, but under the proposed Compulsory Clause the Council might itself have to administer the Bill.

Dr. LYONS: *Quod absurdum est.*

Dr. QUAIN said if the Council approved the nomination of an outside body it would be responsible for it. He protested against having anything to do with schemes or regulations of other bodies.

Dr. HUMPHRY said the matter was one of public importance, and therefore deserved the fullest consideration, involving as it did the lives and happiness of a large part of the population, and also the interests of the profession. It was improbable that the medical bodies would take the matter up, and the only body to which Parliament could look to undertake the work was the body which it had created for the purpose of regulating medical affairs. According to the proposal of the committee the Council would have to institute a board and lay down regulations for its guidance; but it would not be responsible for all its proceedings. The Privy Council would have the ultimate authority and the chief responsibility. The duty proposed or assigned to the Council was no more than it ought to undertake, and if it refused it would be putting off *sine die* the practical application of the rules and principles which it had declared to be of great importance.

Dr. LYONS maintained that the work could be best carried on by means of the medical colleges, lying-in institutions, obstetrical societies, and other bodies of a like nature.

Dr. PYLE called attention to the resolution passed by the Council as far back as 1877, and said that the effect of Mr. Simon's amendment would only be to create still further delay.

Mr. Simon's amendment was then put and negatived.

Dr. LYONS moved a second amendment: "That this Council is desirous to see established an efficient system of education, examination, and registration of midwives, for the care during labour of the women of England and Wales; but the Council is of opinion that the duties should be discharged, as in Ireland, by the various teaching and licensing authorities, chartered lying-in hospitals, obstetric societies, and such-like bodies; and that this Council is prepared to accept the general supervision of this great work, but is not prepared to accept administrative or accounting functions in regard to a scheme which will probably include from 10,000 to 20,000 persons, over whom it would not be possible for it to exercise the requisite supervision and control."

Mr. COLLINS seconded the amendment, which was put and negatived.

The original motion was then put and carried.

The following resolutions were also agreed to without discussion:—

"That as regards the proposition made in the Draft Bill

that any of the funds at the disposal of this Council might be devoted to the purposes of an enactment to secure the registration of midwives the Council is of opinion that this is undesirable, and that such portion of Section 34 as relates to those funds should be omitted from the Bill." "That the Council, whilst offering no opinion as to the appropriate time for legislating on this subject, recommend that in the event of a Bill being brought before Parliament a copy of the measure, and notice of the changes in it, should be communicated to the Council."

The Council then adjourned.

#### SATURDAY, JULY 8TH.

On the motion of Mr. MARSHALL, seconded by Dr. HAUGHTON, the report on the Draft Bill for the Registration of Midwives in England and Wales, adopted by the Council yesterday, was ordered to be transmitted to the Lord President of the Privy Council, together with the minutes of the Council.

Dr. SMITH moved, "That the Visitation of Examinations in the Universities be postponed until the year 1883." He said that in July, 1880, the Council decided to carry on the visitation of examinations systematically from year to year. As a matter of fact only a partial visitation of the universities could be made this year, and therefore he thought it desirable that it should be postponed till next year. His own feeling was that such visitation was not at all necessary, for it was generally admitted that the universities were in the habit of discharging their duties satisfactorily in the matter of the minimum qualification.

After a short conversation the motion was withdrawn.

On the motion of Mr. MACNAMARA, seconded by Dr. HAUGHTON, a resolution was agreed to calling the attention of the Executive Committee to a case reported in the *Daily Telegraph* of June 30th, of a medical student who was summoned at the Dublin Police Court for seeking to bribe a London practitioner to personate him, and pass his examination for him.

Dr. LYONS moved, "That a committee be appointed to inquire into and report upon the alleged probable deficiency of subjects for anatomical and surgical examinations, if fully carried out on the dead body, in London, Edinburgh, and other places, and to suggest such remedies as they may deem expedient." He said the Council was agreed that it was essential that students should be examined on the dead subject, but there seemed to be a difficulty about obtaining the bodies. It had occurred to him that, perhaps, the horse and the ox might be utilised. In that way, indirectly, a good deal of comparative anatomy would be acquired by the majority of the profession, and this would lead to a more humane treatment of the lower animals. Mistakes of the most frightful kind were common in the practice of farriers and others, and a vast amount of cruelty was unnecessarily caused when the intention was only to do good. The committee might also consider how far it was possible to establish an interchange of dead subjects between one portion of the kingdom and another.

Dr. PYLE seconded the motion.

Mr. MARSHALL suggested that the resolution should be altered to read as follows:—"That a committee be appointed to inquire into and report upon the deficiency of subjects for anatomical and surgical teaching and examinations, and to suggest such remedies as they may deem expedient."

Dr. LYONS consented to this alteration, and the resolution was then agreed to. Mr. Turner, Mr. Marshall, Dr. Humphry, Dr. Fergus, Dr. Pyle, Dr. Heron Watson, Mr. Macnamara, Dr. Haughton, and Dr. Lyons (chairman) were appointed to constitute the committee.

Dr. STORRAR moved, "That the Registrar of the Medical Council be instructed to address a letter to the Registrar of the University of Durham suggesting for the consideration of the university whether the time has not arrived when it is expedient for the university to discontinue their 'registration examination for medical students.'" He said that great exertions had been made by the Council from time to time to bring all the examinations in Arts under boards for general education, and do away with Arts examinations of a special character. When these examinations were first instituted the University of Durham, seemingly with a view to meet the demands of the time, established a special examination for medical students. It was not in the proper sense of the word a university examination that led up to any degree. Men from any part of the United Kingdom might attend it,

pass, and then go off to any other school. At first there was a great rush to it. After a few years it was thought expedient that the Council should hold an inquiry into the nature of those examinations, and it proved to be a farce. Dr. Hamilton, who at that time represented the university, was indignant about it, and said it should be stopped. A remonstrance was made, and the result was a great diminution in the number who presented themselves; but gradually it had crept up again, and in 1881 there were thirty-three who passed the examination. At the same time only one man passed in any other examination of the university. Dr. Pyle had informed him that the Oxford and Cambridge local examinations in the north were preferred to those of Durham. Perhaps, then, it was not too extravagant a conjecture that it was the weak men who went up to the examination in question. There was really no necessity for it, and therefore he thought the Council should ask the university whether the time had not come for abolishing it altogether.

Dr. PYLE seconded the motion. There would not be a Senate meeting till October, but he would bring the subject before them on that occasion. He believed that the examination had been a very good one lately, but the inquiry was a proper one to make.

The resolution was agreed to.

On the motion of Dr. STORRAR, the report of the Committee of the whole Council on the conclusions of the visitors of examinations was received and ordered to be placed on the minutes.

Dr. QUAIN moved, "That it be remitted to the President of the Council to bring under the notice of the Registrar-General the case of G. H. Griffin, an unqualified person, who in certain death certificates forged the name of a registered practitioner named D. B. Murdoch." He said that in 1877, when a somewhat similar case arose, the Registrar-General assured the Council that if a clear case were reported to him of an unqualified medical man forging for his own purpose the name of a registered practitioner, he would take the opinion of the legal authorities serving under the Lords of the Treasury as to whether proceedings should not be instituted. There never was a clearer case than the present; for Mr. Murdoch swore that he had not given Griffin any authority to sign his name.

Dr. BANKS seconded the motion, which was agreed to.

Dr. STORRAR moved, "That the examinations of the Intermediate Education Board of Ireland—junior grade, middle grade, and senior grade—be placed in the list of examinations recognised by the Council, provided the certificates contain all the subjects required by the Council." These intermediate examinations, he said, were the outcome of Lord Cairns' Act for encouraging secondary education in Ireland, and they appeared to be of a very high character. The only reflection he had heard made upon them was that they were too high; but that was not a complaint that the Council would give much weight to. They were exceedingly desirous of doing away with all special examinations conducted by medical bodies, or under the superintendence of medical bodies. The only two bodies in Ireland which continued to superintend such examinations were the College of Surgeons and the Apothecaries' Hall; and it would greatly facilitate the discontinuance of those examinations if the intermediate examinations were recognised by the Council.

Dr. HAUGHTON seconded the motion.

Mr. COLLINS said the Apothecaries' Hall of Ireland was perfectly willing to transfer its preliminary examinations to the Intermediate Commissioners.

The resolution was agreed to.

Dr. STORRAR moved, "That the Registrar be instructed to address a letter to the following bodies: the Apothecaries' Society of London; the Royal Colleges of Physicians and Surgeons of Edinburgh; the Faculty of Physicians and Surgeons of Glasgow; the College of Surgeons of Ireland; and the Apothecaries' Hall, Ireland, calling their special attention to the following recommendation of the Council: 'It is desirable that the examinations in general education should be left to the universities, and to such other bodies engaged in general education and examination as may from time to time be approved by this Council.'" He was happy to say that the only body in England which now conducted its own preliminary examination was the Apothecaries' Society, while in Ireland there were only two bodies that did so—namely, the Apothecaries' Hall and the College of Surgeons. Thus the special examinations were both gradu-

ally got rid of. As regards Scotland, there were special difficulties, but the motion would strengthen the hands of those who had to deal with them, and enable them, whenever an opportunity offered, to get examinations established in the country to which the Arts examinations might be transferred.

Mr. SIMON seconded the motion.

Dr. HALDANE said that so far as the College of Physicians and Surgeons in Scotland was concerned they would be quite willing to give up their preliminary examination, provided there were a perfectly open examination in the universities, but as matters stood at present they could not do so.

The motion was agreed to.

Dr. STORRAR moved a resolution instructing the Registrar to send a circular to each of the Indian, colonial, and foreign universities and colleges, asking for information on the following points with respect to their examinations recognised by the Council:—(1) Percentage of highest marks; (2) percentage of pass marks; (3) number of candidates at examination referred to; (4) copies of the examination papers set. He said that seventy-five universities and colleges were specified in the list embracing the universities of India and British North America, some in the United States, one in the West Indies, some in Australia and New Zealand. The question was naturally asked what was the value of those examinations, and that was what they wanted if possible to find out. For himself, he had no positive suspicion that the colonial examinations were a sham; from all he could learn the authorities there had done their best to promote higher education in Arts.

Dr. HAUGHTON seconded the motion, and said that several of the bodies were not teaching bodies at all in the proper sense of the term. He had no knowledge whatever of the Arts examination of the Medical College of Michigan, for instance. He knew that the University of Michigan was a highly thriving and advanced university; and therefore it appeared odd that the university should not be on the list while the college was. Again, the University of California, which was in a very weak condition, was on the list, while all the great universities of America were conspicuous by their absence. The reason given was that these latter bodies never asked to be put on because none of their students ever wanted to come here and register; but that excited a suspicion as to the reason why the other bodies wished to be on the Register.

Dr. FERGUS cordially supported the resolution, and reminded the Council that two years ago he drew attention to the same subject, and proposed several additions to the standing orders, which he was then told it was impossible for the Council to pass.

Dr. TURNER said that in 1879 there were 10 medical students registered from the University of Calcutta, 6 from the University of Madras, 2 from the University of Bombay, 1 from the Medical College at Halifax, Nova Scotia, 9 from the University of Melbourne, 9 from the University of Sydney, 1 from the University of Adelaide, 17 from the University of the Cape of Good Hope, 1 from the University of New Zealand, and 1 from Christ's College, New Zealand—making a total of 57; while in 1881 there were 89 students registered from the corresponding bodies.

The PRESIDENT said there was a strong feeling on the part of the medical men of the United States to ally themselves with this country, and to send students here especially in connexion with clinical study.

The resolution was agreed to.

The following report by the Dental Committee was then read:—"With reference to the cases of John Thomas Lambert and Joseph Walker, referred back to them by the General Council, the Committee find that John Thomas Lambert and Joseph Walker have now answered the communications addressed to them, and that they are in the same condition as regards qualification as other persons who are on the Dentists' Register, and who answered in due time the letters sent them by the Council. The Dental Committee report these facts to the General Council."

On the motion of Dr. E. PITMAN, seconded by Dr. SMITH, the Council resolved:—"That the report of the Dental Committee not having put the Council in possession of evidence to show that John Thomas Lambert and Joseph Walker were not *bonâ fide* engaged in the practice of dentistry, the Council is not, therefore, prepared to order the removal of their names from the Dentists' Register."

Mr. TURNER moved, "That one year's *bonâ fide* apprenticeship with a registered dental practitioner, after being regis-

tered as a dental student, may be counted as one of the four years of professional study." He said the resolution would bring the education for dental students into conformity with the arrangements for medical students.

Dr. WATSON seconded the motion, which was agreed to.

Mr. TURNER also moved, and Dr. WATSON seconded:—"That the three years of instruction in mechanical dentistry, or any part of them, may be taken by the dental student either before or after his registration as a student; but no year of such mechanical instruction shall be counted as one of the four years of professional study unless taken after registration."

An amendment, proposed by Dr. LYONS, to substitute the following:—"That in the opinion of this Council it is desirable that the dental student should spend a period of three years in the study of mechanical dentistry," for the first three lines of the motion, was negatived, and the resolution was then carried.

Sir WM. GULL, in moving "That any or all of the qualifications in Schedule A of the Medical Act be registrable in the Dentists' Register," said that Mr. Simon and himself, as Crown nominees, reserved to themselves, if they considered it desirable, to lay before the Government their views with regard to the registration of midwives. Mr. Bowen had given his opinion that the Council ought not to enter in the Dental Register other than dental qualifications. He entirely demurred to that view, for Section 11, Subsection 6, of the Dental Act gave that power. The Council, therefore, ought to exercise the power first *pro bono publico*. The public, on looking over the Register, ought to be able to see the full status of the people whose names were registered there.

Dr. STORRAR seconded the motion.

Dr. HAUGHTON said that he had many friends among dentists who were graduates in medicine and surgery, and they were all dissatisfied because their qualifications did not appear on the Register. Such persons were entitled to differentiate themselves from barbers who practised dentistry.

Dr. QUAIN expressed a hope that this was the last time the dentist question would ever be brought before the Council, for they had had more trouble about it during the last two or three years than about any other subject since the Council had been in existence. The Register had been altered four times, and now it was proposed to alter it again. He was not going to oppose the motion, because it would be contrary to his views to vote against the advice given by the legal adviser.

Mr. TURNER said his opinion was generally in favour of Sir William Gull's motion, but he felt a difficulty with reference to the Apothecaries' Society, because he did not think that the L.S.A. of that Society represented a "higher degree of knowledge." He would suggest as an amendment, "That any or all of the qualifications in Schedule A of the Medical Act, granted by any of the medical authorities who had power to hold examinations for testing fitness of persons to practise surgery or dental surgery, be admitted to the Register." The Apothecaries' Societies were not examining bodies.

Mr. MACNAMARA said that the amendment would not satisfy him, nor would it proceed at all on the lines that Sir William Gull wished to guide the Council in. The conferring of degrees in dentistry was strictly limited to bodies capable of giving surgical qualifications, and if those qualifications showed a higher degree of knowledge they were capable of being inserted in the Register. The aim of the Council should be to make the dental profession a more respectable body of practitioners, and he had seen so much injury inflicted on patients by the purely mechanical dentist that he wished to encourage as much as possible the obtaining of additional qualifications. That encouragement would be given to them if their qualifications were registered. He hoped Sir Wm. Gull would press his resolution.

Dr. LYONS said that the clause in question had been widely drawn for the purpose of including any qualifications which might be afterwards given on examination, but if the medical authorities chose to give the qualification without examination, such qualification would not be capable of registration. He regretted that the Act in certain of its clauses was not drawn in a more stringent way, and that it had been possible to register persons who pursued other than strictly professional callings. That defect, he thought, ought to be cured in future. But because certain persons were able to get through the back door into a professional body it did not follow that they were justified in neglecting another

portion of the Act, which was clearly mandatory. He had no doubt that the clause was framed with a view of classifying and marking out those who had a superior education, and therefore ought to occupy a superior scientific professional position. He supported Sir Wm. Gull's motion, but he concurred in the view expressed by Dr. Quain, that an effort should be made to exclude mere tradesmen from the profession.

Dr. BANKS supported the motion, which he said the Council ought to pass as an act of common justice to the educated portion of the dental profession. There certainly ought to be some means of distinguishing high-classed dentists from those who followed the calling as an ordinary trade.

Mr. SIMON thought that Sir William Gull's motion ought to be supported, and that it followed almost of necessity from what the Council had already done, but he could not vote for it because the original step taken fourteen months ago was in the teeth of legal opinion.

Dr. SMITH seconded Mr. Turner's amendment. He had no objection to having the qualifications registered with the restrictions therein proposed. He did not think that the clause in question was mandatory, but only permissive, as was evident from the words "if they shall think fit."

Dr. HUMPHRY said his position was the same as that taken by Mr. Simon; he should not therefore vote for Sir William Gull's motion, because he thought the whole thing was an illegal transaction, and that the Council was acting in the face of legal opinion. If, however, the lawyers were correct, the Council ought to insert in the Register theological as well as other degrees.

Dr. PITMAN and Dr. STORRAR spoke in support of the motion.

Sir WM. GULL having briefly replied,

Mr. TURNER said it was evident that his amendment was not likely to meet with acceptance, and he would, therefore, withdraw it.

The motion was then put and carried.

A memorial was read from the British Dental Association calling attention to the completion of the time during which in accordance with the terms of the Council's minutes (July 16th, 1879), examinations should be conducted *sine curriculo* by the Royal College of Surgeons in Ireland. The memorialists reminded the Council that by Section 22 of the Dentists Act it had power to supervise the examinations, and suggested that such power might now be usefully exercised.

No action was taken upon this memorial.

A letter was read from Mr. Barnard Lee, of 130, Lancaster-road, Notting-hill, stating that at 199, Portobello-road, Notting-hill, there was a man evading the provisions of the Dentists Act by announcing himself as a dentist and practising as one, but using no name. The writer inquired whether the Council was disposed, in the interest of the profession, to take up the case. Another letter was read from J. W. Sadler of Burton-on-Trent, calling attention to the fact that a late pupil of his had commenced practice without being qualified, and enclosing his advertisement from the *Burton Evening Gazette*.

No directions were given by the Council with reference to these cases.

A letter was read from the Business Committee of the British Dental Association asking permission to prosecute Mr. T. L. Callender of Bridge House, Burton-on-Trent, and Mr. Godding, representing himself as a member of the Royal College of Surgeons, whose proper address was not known to the Committee, but who was supposed to be Mr. J. R. Godding of 67, Oakley-square, London, for infringing the Dentists Act. The Committee also asked the Council to consider the propriety of granting to the Representative Board of the Association or to the Honorary Secretary, power to take up any case which might arise in the intervals between the sittings of the Council.

Permission was given to Mr. J. S. Turner, honorary secretary of the Association, to prosecute Mr. Callender and Mr. Godding.

Votes of thanks were then passed to Dr. Acland for presiding; to the chairman of the Business Committee, Dr. Pitman, and to the treasurers, Dr. Quain and Dr. Pitman.

The PRESIDENT expressed his high sense of the value of the Registrar's services, and trusted that the Council would allow him to tender him their best thanks for the able and assiduous manner in which he had discharged the complicated duties of his office.

A vote of thanks to the Registrar having been passed by the Council, the session terminated.

## THE BRIGHTON SEWERAGE.

[LETTER FROM MR. ROBERT RAWLINSON, C.B.]

To the Editor of THE LANCET.

SIR,—I have read your article in THE LANCET of the 17th of June last, and have learned that the Town Council have served notice of action for libel upon you for that article. I have also read the report by Sir Joseph Bazalgette upon Brighton Sewerage and Sewer Ventilation. In my opinion the report in a great degree, if not altogether, justifies your article. I have known Brighton for a good share of thirty years. I know the condition it was in, and I also know something of the condition it is now in, and I fear that a full and searching report on the sanitary condition of the town and its suburbs might startle the local authorities, and induce them to spend their subscriptions in improved works rather than on law. I would not write to you, or in any way interfere in this matter, if I did not feel that those who wish best to Brighton would desire to stop the threatened action, which will only waste time and money, and do no good to Brighton. Your articles extend beyond England, as the Mayor of Cannes was over a short time ago making inquiries as to modern sanitary works in England, preparatory to sewerage that town. I think you have written quite as strongly about Cannes as about Brighton, and apparently with less threatening results.

Yours truly,

ROBERT RAWLINSON.

London, July 11th, 1882.

## RECENT BRIGHTON MORTALITY STATISTICS.

THE health of Brighton, judged by the mortality statistics issued weekly by the Registrar-General, although showing a considerable improvement upon that in the preceding quarter, was far from satisfactory during the thirteen weeks ending on the 1st inst. It is true that the death-rate from all causes fell from 29.2 per 1000 in the first quarter to 21.8 in the one just ended; but even this reduced rate exceeded the mean rate for the same period in the twenty-eight large English towns dealt with in the Registrar-General's Weekly Return, and showed a still larger excess upon the mean rate for the whole of London. If we look to the figures for the first half of this year, we shall find that the annual death-rate in Brighton was 25.5, against 22.8 in the twenty-eight towns (which include seven Lancashire towns in which the waste of life is notorious) and 22.6 in London. The statistics of fatal zymotic disease are still more adverse to Brighton. Following the outbreak of enteric fever in the latter part of 1881, Brighton has suffered severely from the epidemic prevalence of measles, whooping-cough, and scarlet fever during the first half of this year. The annual death-rate from what are called the principal zymotic diseases was equal to 6.5 per 1000 in Brighton during the first half of this year, while it did not average more than 3.5 in the Registrar-General's twenty-eight large towns. No less than 25.6 per cent. of the deaths recorded in Brighton during the twenty-six weeks ending the 1st inst. were referred to these "principal zymotic diseases," while the mean proportion of such zymotic fatality in the twenty-eight towns did not exceed 15.5 per cent. A marked reduction in the death-rate has, however, taken place in the past few weeks, and during the fortnight ending the 8th inst. the rate has not exceeded 14.5 per 1000, having been in the first of these two weeks as low as 13.3, while the fatal prevalence of measles, scarlet fever, and whooping-cough has all but disappeared.

# THE LANCET.

LONDON: SATURDAY, JULY 15, 1882.

THE Medical Council showed good taste in abstaining from any discussion of the Report of the Royal Commission on the Medical Acts. Mr. MACNAMARA withdrew a motion expressing a hope on the part of the Council that they might have an opportunity of considering any Bill for the amendment of the Medical Acts founded on the important Report of Her Majesty's Commissioners before it is introduced into the Houses of Parliament. We cannot but think that Mr. MACNAMARA exercised a wise discretion in withdrawing this motion, especially after what has happened. The Government, with excessive regard for the Medical Council, imported two of its members into the Commission, who have done what was perhaps natural on their part, but which does not add to the force of the Report or the impression of impartiality of the Commission. As our readers know, Mr. SIMON and Professor TURNER have signed a joint memorandum against direct representation. Not content with expressing their own opinions, they have imported into their memorandum the dreary commonplaces of all the leading past members and presidents of the General Medical Council against a reform that would immensely add to the efficiency of the Council, and to the scanty confidence with which it is regarded by both the public and the profession. The Government, we venture to believe, will know how to appraise the objections of members of the Council to a reform of that body. Mr. SIMON cannot have strengthened his position as a Commissioner by putting himself so eagerly into that of a witness. Under these circumstances, Mr. MACNAMARA does well to abandon a request that Her Majesty's Government will submit any Bill to the Medical Council before introducing it; in other words, will take the Council into co-operation in framing the measure. If the Council, in addition to its representation on the Commission, were further to be invited to dominate the coming legislation, we need scarcely say that the result would be entirely unsatisfactory to the profession, and disrespectful to the independent members of the Commission, including a Judge so able as Sir GEORGE JESSEL, and a representative of the profession so complete as Sir WILLIAM JENNER.

The Council gave its assent to the general principles of the Bill for the Registration of Midwives, sent down to it by the Lord President of the Council. There were some lively differences of opinion as to certain questions of detail. Mr. SIMON showed a tendency to repeat discussions of the principles on which such a measure should be framed rather than the actual proposals of the draft Bill. He was even more impractical still, for he tried hard to induce the Council to make the measure permissive, or rather to make the Council's responsibility in the matter permissive. Surely we have had enough of permissive legislation; and of all objects to which permissive law is inapplicable, one of the most obvious is the provision of registered midwives for the poorer classes of the community. Mr. SIMON completely

failed to carry the Council with him. He and his seconder, Sir WILLIAM GULL, were almost alone in wishing to resolve "that the Council would not object to be made, under permissive law, the sanctioning medical authority in the proposed matter." Dr. LYONS was scarcely more successful in moving that the duties connected with a system for educating, examining, and registering midwives in England and Wales should be discharged, as in Ireland, by the various teaching and licensing authorities, chartered lying-in hospitals, obstetric societies, and such like bodies. Such a proposal is best met by remembering that what is everybody's business is nobody's. It would be a great evil to have such a multiplicity of bodies for this purpose. The duty to be discharged, though simple, is very urgent, and the sooner it is made the care of a responsible board, under the supervision of a reformed Medical Council or not, the better. The Council has quite enough on its hands already. Its most ardent admirers will not say that it has any authority in obstetrics. Most of its members would probably be a good deal embarrassed with the care of a case of natural labour; and there is much to be said for creating a board for this purpose entirely independent of the Medical Council.

This view is strongly supported by the unprofitable and undignified appearance made by the Council in connexion with the administration of the Dentists Act. Its action in this matter has been very much disapproved by all who have watched it. The registration of anybody who could boast of ever having drawn a tooth, even a tooth that should not have been drawn, was felt at the time to be a scandal. The loose definition of the word "dentist" brought about a rush to the Register from which the dental profession will not recover for many years to come. All respectable members of the profession feel this acutely, and, naturally enough, the British Dental Association urges the Council to erase names which have been entered on such slight grounds. But it is more easy to register than to de-register, and the Council escaped too easily from its difficulties by moving, "That the Council are not prepared to take steps, as suggested by the Dental Association, to erase names which have been placed therein by the Council under legal advice." This reference to legal advice is scarcely fair. For there seems no doubt that if the Council registered the thousands of names in the Dental Register under some legal advice, it did so contrary to a large body of legal opinion, including that of Sir JOHN HOLKER and Mr. (now Mr. Justice) BOWEN. Great efforts were made, which seemed to have a very exciting effect on Dr. QUAIN, to have these opinions elicited and published in the Minutes, but the Council, with more prudence than candour, ruled "that the opinion of counsel be considered confidential." We protest against the Medical Council being occupied in registering dentists, midwives, &c. Its business is to register fully equipped medical men, and this occupation is enough for it.

MANY a time and oft during the past seven years the question of instituting a compulsory examination in Elementary Anatomy and Physiology at the end of the first year of professional study has been discussed at the Royal College of Surgeons of England, at the General Medical Council, at the Royal College of Physicians, and elsewhere.

This journal has given up scores of columns to the publication of editorial comments and criticism, of notices, advocacies, complaints, and letters relating thereto. As long ago as Nov. 11th, 1875, Mr. MARSHALL, at the Council of the Royal College of Surgeons, proposed an elaborate scheme for compelling all candidates for the diploma of Member or Fellow to pass a compulsory and authoritative examination at the College in elementary anatomy and physiology at the end of the first winter, or immediately after the beginning of the succeeding summer session. That scheme we criticised in great detail in our issues of Nov. 20th and 27th and Dec. 4th of the same year. In the year 1877, the General Medical Council, on the motion of Dr. HUMPHRY, approved the principle of holding compulsory elementary examinations at the end of the first winter session; and in February, 1880, the Royal College of Physicians did institute such an examination. On May 13th of the same year (see THE LANCET, May 15th, 1880, p. 784), Mr. MARSHALL brought the matter once more before the Council of the Royal College of Surgeons. Sir JAS. PAGET seconded Mr. MARSHALL'S motion, which was carried with only one dissident. The purport of the motion was to the effect (1) that the Council should proceed, as soon as practicable, to institute an examination in elementary anatomy and physiology, and in such other subjects as the Council should from time to time determine to be passed by all candidates for the diploma of Member or Fellow, at or after the expiration of the first year of study; and (2) that it should be referred to the Committee on Examinations in Anatomy and Physiology to prepare the necessary regulations for defining and conducting such examinations. The report of this Committee was presented to the Council two years later (see THE LANCET, May 13th, 1882, p. 807). This Committee, in conference with the Committee on Additional Examinations, reported that, however desirable such an examination might be, it was not practicable to conduct it at the College; and suggested that, in lieu of the proposed examination at the College, an examination should be held at the various recognised medical schools, at the end of the first year of study. This suggestion was duly commented on and otherwise noticed in our columns on May 20th (p. 830), and June 17th (p. 993.) On June 10th (p. 971) we announced that the Council of the Royal College of Surgeons had decided to call the attention of the authorities of the various medical schools to the recent resolution on the establishment of the examination at the end of the first year, and had resolved to invite the teachers of anatomy and physiology to confer with the Joint Committee of the College with the object of devising the best means of carrying the resolution into effect. On June 24th (p. 1049), we published the interrogations that had been addressed by the Committee of the College to the teachers of anatomy and physiology on the subject of the proposed examination. Lastly, on the 1st instant (p. 1085) we gave a report of the Conference held on the 26th ult. between the teachers of anatomy and physiology in the various medical schools of England and the Committee of the College. At that conference nearly every one of the metropolitan and many of the provincial teachers were present. "The scheme," we stated, "was subjected to a long and full discussion, and finally certain resolutions were all but unanimously agreed to by the teachers present.

These resolutions were to the effect that it is desirable to hold such an examination in elementary anatomy and physiology at or after the end of the first winter session devoted to anatomical and physiological study; that the examination should be conducted at the various medical schools by the teachers of those schools; that the subjects of the examination should be elementary anatomy and physiology, but that the definition of these terms should be left to the discretion of the individual teachers; that the examination should be conducted by means of written papers, and also orally or practically; that the exact time at which to hold the examination should be left to the discretion of the teachers, but that no student should be allowed to present himself for the Primary Examination for the membership of the College of Surgeons until at least six months after passing this preliminary examination. The purpose of the conference was abundantly fulfilled, for the College authorities have obtained the sanction and promise of co-operation of the whole body of the teachers," &c.

We have been at the trouble to prepare the brief *résumé* of the history of this examination in elementary anatomy and physiology, because in some quarters there is an affectation of surprise and a pretence that the matter has been clandestinely matured. Mr. BUTLIN, for example, who is intimately associated with the tutorial departments of one of the largest metropolitan schools, assures us in a letter published in another column—"I gather from conversations held during the past few days, that the large majority of the members of the various hospital staffs are not aware of the real character of the first year's examination proposed by the College of Surgeons." If Mr. BUTLIN means that he finds the majority of the general staff of hospitals to be ignorant of the real character of the examination, we have no hesitation in accepting his statement, inasmuch as physicians and surgeons do not, as a rule, trouble themselves with the details of the arrangements made for teaching first year's students elementary anatomy and physiology; but if, on the other hand, Mr. BUTLIN means that a large majority of members of the hospital staff whose business it is to teach anatomy and physiology are not aware of the real character of the examination, we must either impugn the correctness of his conclusion, or hold the teachers thus referred to guilty of an inexcusable disregard of those events that should concern them most closely. We can believe that the lecturer, say, on obstetrics, or medicine, or botany, or medical jurisprudence, might, if asked to give his views on the subject, manifest not only profound ignorance but profound indifference likewise. He might fairly reply that he had enough to do in taking care of his own proper subject without meddling with those outside his domain. But we are wholly unable to understand how the lecturers and teachers of anatomy and physiology can excuse themselves if it be true that they are not aware of the real character of the examination.

The arguments that Mr. BUTLIN adduces against the proposed examination are equally unsatisfactory. He alleges that the examination "involves an entirely new principle, and a serious departure from the custom of the schools." Even if it be granted that both these propositions are true, it would not follow that the objections are valid. It

may, however, be replied that there is neither a new principle nor a new departure. The Royal College of Surgeons has for many years insisted that the certificates of attendance on the several courses of lectures for the primary examinations "must include evidence that the student has attended the practical instructions and examinations of his teacher in each course." The only novelty in the regulation for the first year's examination is that the attendance on the examinations shall be a fact and not a mere form, that the student shall not only be present at the examination, but shall show proficiency. In this way the regulation acquires a high disciplinary and educational value of which the best teachers will, we believe, be eager to avail themselves. Though the new examination may increase the responsibility of the teacher, it also enhances his dignity and power. But without this countervailing advantage there are not a few educationalists who would welcome any reasonable augmentation of the responsibility of the teachers of anatomy and physiology. These teachers are always well paid, either directly or indirectly, and have usually the first charge of the training and character of the embryo practitioner. On them must in a large measure depend the moulding of the student's mind and habits, and it is right that they should be made fully conscious of their responsibility.

When Mr. BUTLIN formulates specific objections he enters upon troubled waters. In the first place, he affirms that "the business of the schools is to teach, and not to examine for diplomas." This statement includes at once debatable doctrine and, so far as it has reference to the examination in question, a travesty of fact. Neither the Royal College of Surgeons nor any other licensing body is likely to relegate its examining functions to the schools. At most the innovation the College now seeks to introduce is intended to give better effect to existing regulations for the education of its candidates. As to the propriety of teachers examining their pupils, Mr. BUTLIN entertains opinions which are not shared by many of the best authorities on education. For some years the opinion has been steadily growing, that in order to make examinations thoroughly useful as an educational agency they should be carefully correlated with systematic teaching, and that for this purpose the examinations should be conducted by those who actually teach, and only rarely by independent persons. Mr. HENRY LATHAM, among many excellent observations in his work "On the Action of Examinations," says: "It makes all the difference whether the teaching is subordinate to the examination or the examination to the teaching. .... As long as examinations were conducted only in the schools and universities the educational effects were kept in view, and the range of the examinations was made to correspond with that of the work" (p. 11). And again: "When an educating body has the control of the examinations, they can take precautions for preventing the evil arising from over-eagerness in competing. Hence the performances of a pupil in a series of examinations connected with a definite course of instruction afford a better criterion for judging of him than does a display in an examination open to all comers; and they also enable us to judge, in some degree, of moral qualities, such as application and perseverance" (p. 404). Nothing could be easier than to quote volumes from the best writers in support of this view of the educational value of examinations.

For the recognition of this sound principle the College of Surgeons deserves praise. In the second place, Mr. BUTLIN maintains that "it is very undesirable that schools should be placed under the control of any licensing body." Will he, then, contend that the schools should be independent of such control? If the College of Surgeons have the power to frame regulations, to impose restrictions, to recognise or refuse to recognise a teacher, it is a waste of words to discuss whether or not it have a prescriptive right to test the quality of the teaching. Moreover, while Mr. BUTLIN urges that the schools should be free from the control of the licensing bodies, he insinuates in another portion of his letter that the College should itself conduct the examinations. If an inquisitorial examination were forced on the schools by the Royal College of Surgeons, or any other licensing body, at the end of the first year of professional study, it is not obvious that the dignity and independence of the schools would thereby be preserved. Thirdly, Mr. BUTLIN argues that, "if the schools undertake to hold an examination in certain subjects for one licensing body, they may fairly be required to hold examinations in special subjects for all licensing bodies." If the word *properly* be substituted for *fairly* we shall cordially agree with Mr. BUTLIN. It is eminently desirable that those who are responsible for the regulations of the medical curriculum should not only insist that certain courses of instruction should be followed, but that guarantees should be furnished that these courses have been *profitably* pursued. Attendance on lectures should be made to include also proficiency in the class and sessional examinations. This is all the College asks. With Mr. BUTLIN's fourth objection we should prefer not to deal. Questions of money payments and other remuneration for work or duty performed are always tender, and require delicate handling. It may, however, be mentioned, that of all those who are engaged in teaching medicine and its allied branches of art and science, none have such large stipends and such fat emoluments as the lecturers, teachers, and demonstrators of anatomy and physiology. The teachers of these subjects by sessional fees, by private classes, by "coaching," and in other ways, enjoy a peculiar and exceptional position among those who are engaged in the education of medical students. None but them can earn a livelihood by teaching, and they can do it easily. It does not seem a very great hardship that they should, without extra remuneration, give proof that their efforts and their industry have been commensurate with the liberality of their professional and pecuniary rewards. Mr. BUTLIN's letter concludes with a minatory reminder that "the teachers of anatomy and physiology do not constitute the schools, whose opinion of the scheme has not been sought." At the conference of the teachers of anatomy and physiology with the Committee of the Royal College of Surgeons there were over thirty representatives from the nineteen medical schools of England. Mr. BUTLIN seems to imply either that the invitations were too narrowly limited or that the wrong persons were asked. As there are probably between forty and fifty persons, including demonstrators, comprised in the constitution of each of the medical schools, it follows that nearly one thousand persons should have been invited to the

conference, instead of forty. What proportion of this host is likely to give effect to Mr. BUTLIN'S threat that the opinion of the schools "probably will be given unasked; and if it be adverse," whether or not "the College will scarcely care to push its authority so far as to force this examination on the schools," must be left in anxious and perplexing uncertainty. We know the opinions of the lecturers on anatomy and physiology; we await with trepidation the decision of the "schools."

THE Memorandum on Vaccination which has recently been prepared by Mr. R. D. SWEETING, resident medical officer to the Fulham Small-pox Hospital, and which has been issued by the Metropolitan Asylums Board, is a document of considerable interest and one which is well calculated to remove doubts as to the value of vaccination from the minds of those persons who, having been disquieted by some of the arguments of anti-vaccinationists, are still capable of estimating the value of trustworthy statistics bearing upon the subject.

Dealing first with the general history and the physiological theory of vaccination, Mr. SWEETING goes on to show, by reference to mortality statistics, how enormous has been the reduction in the small-pox death-rate since the introduction of vaccination, and he proves conclusively that such decrease has not, as is often alleged, gone hand in hand with a similar decrease in general mortality, but that, on the contrary, it has been maintained even during periods when the general mortality has undergone a distinct increase. Examination of the figures bearing upon this point indicate clearly that since the general adoption of the practice of vaccination as the result of JENNER'S remarkable discovery, the saving of life which has been effected by the prevention of small-pox far outweighs any corresponding diminution either of the general mortality or of the mortality from those specific fevers which are known to be principally affected by general sanitary improvements. So also, Dr. GUY, F.R.S., in his recent paper before the Statistical Society has already shown that the progressive decrease of mortality from small-pox not only commenced before the introduction of general sanitary measures, but that, apart from vaccination, no other cause has been in operation, coincidently with that decrease, to which it is possible to attribute the effect brought about.

Reviewing the facts which have come under Mr. SWEETING'S own observation, we find that since the establishment of the hospitals provided by the Metropolitan Asylums Board the mean small-pox mortality has been at the rate of 8 per cent. of admissions amongst the vaccinated, and 44 per cent. amongst the unvaccinated. And we are further informed that a patient is never entered as "unvaccinated" merely because no indication of vaccination can be found, but only when, in addition to this, the fact itself is admitted either by the patient or by a near relative on his behalf. This explanation will, we trust, finally dispose of the assertion so frequently made that some of the fatal cases grouped amongst the "unvaccinated" had as a matter of fact occurred in patients whose vaccination was rendered either indistinct or altogether invisible by reason of the eruption of small-pox.

The well-known immunity from small-pox experienced by

the hospital staff is another matter with regard to which most erroneous statements have often been made, and the argument in favour of vaccination which has been very properly based upon it has frequently been met by the statement that these officials, and especially that the nurses, owe their protection not to vaccination but to antecedent attacks of small-pox, many of them having been hospital patients. The actual facts as to this are now before us, and they are of the highest value. Mr. SWEETING admits in the first instance that there has been no absolute immunity from attack amongst the officials; that is to say, he claims no more for vaccination in the hospital than can be claimed for it when it is properly performed outside the hospital—namely, that primary vaccination followed by successful revaccination gives an almost complete immunity from an attack of small-pox even under circumstances of constant and direct exposure to infection, and that, as far as known, it confers an absolute immunity from a fatal attack. He next shows that out of a total of 1061 officials who have been connected with the various small-pox hospitals belonging to the Metropolitan Asylums Board during a series of years, only 81 had formerly been patients, and that hardly any of these had been appointed to act as nurses. Indeed, at the Fulham Small-pox Hospital not a single nurse had ever been chosen from among the patients, and out of a total of 295 officials of various grades, only 42 had suffered from small-pox before appointment, thus leaving 253 unprotected by a prior attack of the disease. Grouping all the information on this point as regards all the small-pox hospitals, together with the hospital ships *Atlas* and *Endymion*, it appears that since they were opened thirteen officials in all have had small-pox. Four of these had, owing to an oversight, not been revaccinated, and the disease seized upon them with unerring aim; two others had contracted small-pox before the date at which revaccination could have protected them, and the remaining seven had attacks of a very mild description. In other words, out of a total of over 1000 officials, many of whom had been by day and by night exposed to a highly infected atmosphere, only seven contracted small-pox, and in these exceptional instances the disease was disarmed of all its worst features.

The anti-vaccinationist has, however, often met the inference which is naturally drawn from such facts by alleging that the hospital officials are a picked body of healthy persons, and that they are hence not liable to contract infection. Such an argument will, we trust, be finally silenced by some further facts recorded in the memorandum, and which are to the effect that in the hospitals devoted to the reception of specific fevers other than small-pox no less than 133 of a similarly selected staff of officials had, during the past ten years, been attacked with fever. The attacks were also of a severe type, for no less than 25 attacks terminated fatally. Thus infections against which there is no such protection as vaccination affords in the case of small-pox, were not held in check by the condition of healthiness referred to.

One other important matter is worthy of note. It is well known that, owing to vaccination, attacks of small-pox occurring when the protective influence has somewhat subsided, are often so modified that it becomes extremely difficult to diagnose them correctly, and that, in consequence, many patients have to be kept under observation for some

days before it can be decided whether an eruption under which they are suffering is that of small-pox or not. Now many patients who, at the end of their period of observation, are found not to have small-pox are, in the absence of isolation wards, regularly admitted in the general small-pox wards. So, again, mothers not suffering from small-pox are at times admitted with children having the disease, and healthy infants are also occasionally taken in with their mothers who are suffering from the malady. In all these cases the individuals in question are vaccinated, either on admission or directly it is ascertained that they are not suffering from small-pox, and the result of many years' experience is to the effect that, provided the vaccination can be effected not later than the third or fourth day following an exposure to infection, the protection afforded them has never failed. And, on the other hand, in cases where an incorrect diagnosis as to small-pox has been made and acted on, the patients have contracted the disease, because the immunity conferred by vaccination was not afforded them. The evidence brought forward on this point is similar to that which has been observed in other small-pox hospitals, and even if it stood alone it must be regarded as affording a crucial test of the protective influence of vaccination.

## Annotations.

"Ne quid nīmla."

### THE COLLEGE ELECTION.

THE result of the election of Members of Council of the Royal College of Surgeons held last week rather tends to confirm the idea that the College Council is fast becoming a strict oligarchy. The only provincial candidate was a gentleman who at a considerable sacrifice of time has served the College faithfully for eight years. He sought for re-election, but has been displaced by a surgeon on the staff of a Royal Hospital. Mr. Baker was very unfortunate. A general impression seemed to prevail that the opposition to the re-election of the three retiring candidates would not be pressed; and Mr. Baker's friends were evidently deceived by the apparent absence of interest or of excitement. The supporters of his opponent embraced the opportunity and scored a victory. We have no wish to excite jealousy and rivalry among the various sections of the Fellows, either metropolitan or provincial, or those who are connected with medical schools and those who are not; but it is extremely undesirable that the majority of the Members of the Council of the Royal College of Surgeons should be attached to a few of the largest schools. The result of the late voting will hardly encourage either of the candidates representing the smaller schools to again seek election on the Council. Nothing could be more detrimental to the welfare of the College than that the impression should grow into conviction that only Fellows connected with big schools may hope to be elected. There are many Fellows representing the interests of the profession outside the influence of those large schools. These will decline to come forward as candidates if the result of the election is always to be a foregone conclusion. There can be no question that our large schools by working together and playing into each other's hands may, if they wish, secure all the seats in the Council. Such machinations must, however, be met by strong combinations of independent voters. An analysis of the voting last week throws an unpleasant light on the way in which an election may be won. Two hundred and forty-five Fellows recorded their votes, of

which one was declared to be invalid through informality. Three members had to be elected, so that each Fellow was expected to make a selection of three out of the six candidates. Fifty-six of those who voted, or 22·86 per cent., exhibited their intelligence and capacity for this duty by "plumping," that is, giving all their support to one friend. We are glad to record another confirmation of our persistent contention, that the best candidates can always dispense with the silly help of "plumping." Of the 165 votes polled by Mr. Marshall, only 3·03 per cent. were "plumpers," and of the 144 votes given to Mr. Power, only 2·08 per cent. were "plumpers." On the other hand, Mr. Croft's 103 votes included not less than 20·38 per cent. of "plumpers," and the three unsuccessful candidates received from 13·43 to 16·6 per cent. It is useless to pretend that so large a proportion of the Fellows stultify themselves unasked. We do not wish to insinuate that any of the candidates encouraged "plumping" in their behalf; but their friends were not equally scrupulous. Mr. Croft's case is a specially hard one, and those who know this gentleman best will sympathise most heartily with him in the painful position into which his zealous but injudicious friends have forced him. Mr. Croft is deservedly held in high esteem as a surgeon and teacher. His election will, however, not be without its use if it gives the death-blow to the foolish and undignified practice of wholesale plumping.

### THE EGYPTIAN EXPEDITION.

THE medical arrangements for the force to be despatched to Egypt have been very carefully considered by the War Office authorities, and ample provision will be made for the troops in the way of assistance, both regimentally and in the field hospitals. Two bearer companies of the Army Hospital Corps, eight field hospitals, general hospitals at suitable localities, and hospital ships to convey the sick and wounded without delay to the base of operations or to England will be provided. The *personnel* of a bearer company, when complete, consists of eleven officers and 213 men, including the Army Service Corps, with full equipment in the matter of tents, ambulances, surgery waggons, water carts, &c.; those furnished with mountain equipment are given litters and cacolets, carried by mules or ponies, instead of ambulance waggons, as for a campaign in a sandy desert like the neighbourhood of the Suez Canal they are more suitable than wheeled carriages. Each field hospital is equipped for 200 beds; its staff is seven medical officers, one officer (Army Hospital Corps), and a proportion of non-commissioned officers and men for nursing and hospital duties. Medical and surgical appliances are carried in pharmacy and store waggons. Large quantities of reserve medical stores, medical comforts, disinfectants, and lime-juice are being shipped by the Commissariat Department, and as the medical service of the army contains numerous officers who have experience of the recent Afghan and South African campaigns, we feel confident that nothing will be omitted or neglected.

### "SURVIVAL OF THE FITTEST:" A PARADOX IN THE SCIENCE OF HEALING.

WHY, if it be natural and expedient that only the "fittest" should survive, are we as a profession chiefly interested in prolonging the lives of those who have been rendered unfit by disease or accident? This question, which apparently points to a paradox in science—supposing the art of healing to be in a philosophic sense scientific—has been referred to us by Mr. Harold G. Dixon, B.A., for discussion, and it certainly suggests considerations which it may be worth while to set before our readers as subjects of thought at leisure. It is not necessary to be "of a speculative turn of mind" in order to be a sound and useful prac-

itioner, but it is desirable, as far as possible, to satisfy the inner conscience that what we are doing in the practice of our art is in harmony with the purpose and plan of Nature. If it were really a fact that the whole business of our lives, the work to which we devote the best of our strength and intelligence, had for its object to antagonise the natural course of progress as regards the race, although compassion for the individual might impel us to continue the effort, it would certainly damp the ardour of our enterprise to reflect that those we are striving to keep alive ought in the interests of posterity to be left to die. The seeming paradox is in truth a fallacy.

"Survival of the fittest" is not the same thing in its result as "adaptation to circumstances." Development through, and by, the environment, is the method of Nature, but this does necessitate that man should be "the creature of circumstances." The environment is not a constantly progressive agency of development. It is itself subject to the law of survival. It cannot therefore be absolutely or abstractly true that the fittest for the existing conditions of life in any particular place or epoch ought to survive! For example, it is possible to conceive of a state of physical circumstances which should for a time render a part of the earth's surface so obnoxious to the higher grades of animal life that only the lower forms could live. This state of matters, atmospheric and meteorological, might continue a mere moment in the history of the planet and yet seem to be for ages in the history of organism. Obviously it would not be in harmony with the law of Nature and development that only those animals which were fittest to live amid the transitory circumstances should survive. We, too often, forget that our knowledge of fact is not the measure of truth. The horizon may seem to extend as our powers of sight are enlarged, but we can never do more than scan a limited province of fact from our own low and little standpoint. It is wholly out of our power to determine whether the particular type of development which seems to be making way in the world and asserting its superiority by survival, and is for a time regarded as normal, is the best type or that which is destined to endure and be perfected. It may well be that what we call good and true and beautiful may be only relatively and temporarily so, as regards the momentary surroundings and conditions of life. It is not for us to prescribe the course of natural selection. All we can be quite sure about is the simple axiom that life is in itself excellent. The underlying principle of Nature is "live and let live"—in a scientific sense. Whatever tends to shorten or impair life must be treated as an enemy. We do not know the plan of the campaign as a whole, but we may feel quite sure of the fact that "survival" is the aim of Nature, and all that tends to oppose survival ought to be antagonised.

The fallacy of the paradox which has been submitted to us lies in the fact that only part of the truth is stated. The law of "survival of the fittest" applies to the environment itself not less than to the living organisms within it. The surroundings of life are progressively changing as well as the subjects of life. There is a perpetual struggle for supremacy between the two, and it is always an open question whether the resultant of this struggle will be found to embody a greater or less modification of subject or circumstance. Our duty as practitioners of the art of healing does not relate to the surroundings, except in so far as these may be regarded as tributary to the central fact of life. If we can modify the conditions and circumstances of existence so as to render life easier, it is in our day's work to do this, and to do it heartily; but the commission we hold is to prolong life, and to fight against all that tends to destroy or weaken it. In so doing, we are not merely benefiting the individual, but the race, because, so far as we know, man is the highest

created organism, and as such he is destined to dominate circumstances. For us "man" takes the form of *men*. The race may be higher than the individual, but it is with the latter we have to deal. We are only cognisant of life in its individual manifestations. As regards the total amount of life in the world, or its destined distribution, we are and must remain in ignorance. As men, we have to help men, and to help them to live in spite of the diseases and weaknesses which threaten them with death, and which too often put an end to existence notwithstanding our efforts to prolong it. Science, not less than humanity, bids us look to the individual, and strive for the saving of *his* life. It is in this enterprise alone that our labour can be worthy of Nature and our work useful and sound.

### THE BACILLI OF TUBERCLE.

FOR the demonstration of tubercle bacilli in the sputum of phthisical patients Baumgarten recommends the following method as more convenient than those of Koch and Ehrlich. A little of the sputum is dried on the cover-glass, as recommended by the latter, and then treated with potash—one or two drops of a 33 per cent. solution of caustic potash added to a watch-glass of distilled water. The tubercle bacilli can then be readily seen with a magnifying power of 400 or 500 diameters, and a little pressure renders them still more distinct from the enclosing detritus of tissue. In order to preclude the possibility of confounding the bacilli of tubercle with those of other species, the cover-glass may be raised and placed aside until the layer of fluid on its under surface is dry, and then passed two or three times through a gas flame, and then on it may be placed a drop of an ordinary watery solution of aniline violet or any other nucleus-tinting preparation of anilin. All the putrefaction bacteria then appear under the microscope as an intense blue or brown (according to the testing agent and its strength), while the tubercle bacilli remain absolutely colourless, and can be seen with the same distinctness as in the ordinary potash preparation. The whole process does not occupy more than ten minutes.

In a recent lecture to the Berlin Reichsgesundheitsamte, Professor Billroth discussed some of the practical aspects of Koch's discovery. He pointed out how the accumulating knowledge of the coarser pathological relations of tubercle have led to the conviction that the discovery must shortly come, and he paid a tribute to the investigations of Villemin as having constituted the first and greatest step in the discovery—the step of demonstrating that tubercle is inoculable. This proved its dependence on a transferable virus, although we are only now able to eliminate the possibility that the virus might be of simply chemical nature. The various degrees of individual proclivity to suffer, observed in man, render it very important to study the variations of proclivity which are observed in animals. As a rule it appears that the carnivora are less susceptible than the vegetable feeders (an unpleasant fact, by the way, for vegetarians). In the case of man, the only safeguard is the normal unsuitability of the soil, apart from the existence of inherited fitness. But another reason why local tubercle often exists without general infection—why, for instance, scrofulous caries of a rib so often exists without a general infection—is due to mechanical conditions. At the periphery of such a tubercular focus, in a bone or a lymphatic gland, there is an induration which probably hinders the exit of the tubercular organism and its passage into the blood current. The necessity of a high temperature, such as that of the blood, for the growth of the organism probably lessens very much the extent of the disease in man, since, if the germs could develop out of the body, they would probably be ubiquitous. While the discovery of Koch raises into even greater importance than before the inherited predisposition, it will probably lead to some modification of our views as to the

influence of that predisposition. Cases may be due to infection which are now regarded as the result of inheritance only. A consumptive mother, for instance, may infect a child through a pocket-handkerchief; moreover, the germs may be received by eating the flesh of infected animals. Certainly the conclusions are sufficiently probable to make it incumbent on us to treat consumption as in a measure an infectious disease.

### THE DEARTH OF MORTUARIES.

THE urgent want of mortuaries in the central districts has been brought prominently before the public this week by the sudden death of a gentleman while ascending the staircase of the new Law Courts. He fell just as he had reached the room No. 96; and when application was made to remove the body to the mortuary adjoining St. Clement's Church, the applicant was informed that the mortuary was "full of rubbish, and there was no room for any more." This irreverent comparison, if the report be true, must have greatly aggravated the horrors of the case. We can scarcely believe that even the meanest parish official would be satisfied with such an excuse. The London mortuaries are few and far between; but if these are to be filled with rubbish, and bodies compelled to lay where they fall till after the coroner's inquest, the fact had better at once be known and other measures taken. Certainly the dead-house, as it now stands behind the cab station to the east of St. Clement's Danes, and in the very centre of all the traffic of the Strand, is a disgrace to the parish; but the body would be better placed there than left in one of the offices of the Law Courts. In the neighbouring parish, St. Mary-le-Strand, the mortuary is admirably calculated to facilitate the spread of disease, being situated under the church, and so built that the effluvia has, it is stated, often caused serious inconvenience to the congregation. There was consequently a good reason for closing this mortuary. While this difficulty was occurring at the Law Courts another similar case happened close at hand in a common lodging-house in Portugal-street, Chancery-lane. Here an old woman was found dead in her bed, and, there being no mortuary available, will have to remain there for four or five days. As the death was not due to a contagious disease, we presume that the other lodgers, who sleep in the same room, will not be compelled to leave, though the sanitary condition will not be improved by the prolonged presence of a corpse in a dormitory where a maximum of 300 cubic feet is allowed per bed. So much has been said and so little done on this subject, that we must resign ourselves to the feeble hope that our great grandchildren will perhaps live to see London properly organised in this respect.

### COLLEGE OF PHYSICIANS IN IRELAND.

Two important appointments in the gift of the Fellows were filled on the 7th inst.—viz., the King's Professorship of the Practice of Medicine, and the Professorship of Midwifery in the School of Physic of the University of Dublin. Dr. J. Magee Finny, a graduate in medicine of Trinity, Fellow and Registrar of the College of Physicians, and physician to the City of Dublin Hospital, was elected King's Professor of Medicine. Dr. Finny, we may add, has well earned the reputation he is held in as an accomplished physician, and there can be no doubt his election will be approved by the profession. For the chair of Midwifery there were six candidates—Dr. J. Rutherford Kirkpatrick, a Fellow of the College of Physicians, and an ex-Fellow of the Royal College of Surgeons in Ireland, being successful. So far back as the first week in April (see THE LANCET, p. 581) we mentioned this gentleman as a probable successor to Sir E. B. Sinclair, a prognostication which has been justified by the result.

### LIGATURE OF THE INNOMINATE ARTERY.

OUR last report of Mr. Thomson's case of ligature of the innominate artery is to the twenty-seventh day after the operation. The patient continues to do well, temperature normal, pulse 86; the track of the drainage-tube has healed, and only a small superficial sore now remains unhealed. The aneurism is without pulsation and is becoming smaller. This case will no doubt revive the oft-discussed question of the justifiability of this operation. Of late years the general opinion has been against it, and in most of the surgical textbooks this view is strongly expressed. It is doubtful how often the operation has been carried out. There are five cases attributed to Dupuytren, Lynch, Pirogoff, Bergelsky, and Peiscotto, which do not rest on sufficient evidence to enable us to include them in our list of cases; in all of these cases the operation, whatever it was, proved fatal. But there are twelve undoubted cases performed respectively by Mott (1818), Graefe (1822), Norman (1824), Arendt (1824), Hall (1830), Bland, Lizars (1837), Hutin (1842), Cooper (1859 and 1860), Gore, and Smyth. Of these, eight cases perished from hæmorrhage, one from acute pericarditis, one from inflammation of the sac of the aneurism and pleuro-pneumonia, and one from blood-poisoning. Smyth's case is the only one that recovered, and this only after the patient had experienced four attacks of secondary hæmorrhage, and had had his vertebral artery ligated. In many of the fatal cases, although death took place many days after the operation, the aneurisms did not show any evidence of consolidation. We shall be very glad if Mr. Thomson's case prove ultimately successful, as it now promises to do. But although a month has elapsed since the operation and all looks well, we cannot forget that in two cases—Graefe's and one of Cooper's—death occurred from hæmorrhage on the sixty-seventh and forty-first days respectively. Recent surgical advances have altered the position of this operation to some extent, for they have provided us with several materials which, while successful in leading to the permanent occlusion of the artery, do not cause suppuration of its coats. This removes one great source of danger. But the deep position of the artery, its shortness and its relations to other important structures, render the procedure a very difficult one. There are at least four cases reported where the surgeon has been unable to complete the operation.

Since the above was written Mr. Thomson has forwarded the following particulars of the progress of his case:—"My case has now reached its thirty-fourth day. On the thirtieth day there was some bleeding through the sinus, which reopened. Bleeding stopped spontaneously, and has not recurred. Patient has still normal temperature—in morning, pulse 88. Tumour perfectly still and much reduced in size. Some pulsation apparent in region of the ligatured vessel. No carotid, temporal, or radial pulse."

### A GOOD EXAMPLE.

AT the recent annual inspection of the 2nd North Yorks Volunteer Rifles, the medical staff, with their detachment of sick-bearers, marched past with the regiment. After the usual manœuvres had been completed, the inspecting officer, Col. Mockler, reviewed the ambulance corps, which consisted of Surgeon-Major J. W. Taylor, Scarborough; Acting Surgeon W. T. Colby, Malton, and Acting Surgeon R. Bruce-Low, Helmsley, together with one sergeant and twelve bearers. The equipment comprised three stretchers, Lieut. McLure's patent, a field companion, a field haversack, water bottles, &c. Dr. Taylor put them through the stretcher drill, lifting and carrying the wounded, after which the improvised methods of aiding wounded men on the battlefield were shown. The supposed wounded were laid on the grass in front of the detachment, and the

lifting and carrying of these men in various postures excited great interest in the minds of a large body of spectators. Col. Mockler then presented to each of the men the certificates of proficiency which they had obtained after examination before an Army Medical Board some weeks previous to the inspection. These certificates were signed by Surgeon-General Shelton and Brigade-Surgeon Tippetts, and certified to the knowledge of the bearer in stretcher and ambulance drill and in field dressing. Each man wears on his right arm a brassard on which is the Red Cross. The highly efficient state of this ambulance detachment is entirely due to the unwearied efforts of Surgeon-Major Taylor, who has devoted much time to the teaching of these men. Col. Mockler complimented Dr. Taylor and his corps upon their smartness and efficiency. It would be well if every other volunteer regiment was prepared with such a necessary and important addition to their *personnel*.

### THE POISONS OF THE DAY.

THE current number of *Macmillan's Magazine* contains an important and interesting article by Dr. Hubbard, Vice-President of St. Mary's Hospital, on "The Poisons of the Day—a new Social Evil." In this country we find the curious anomaly of the sale of poisons being governed and restricted by two distinct series of Acts of Parliament having diverse interests and objects. The Pharmacy Act was intended to restrict the sale of drugs for the safety of the public, whilst the Medicine Stamps and Medicine Licence Acts foster and facilitate their sale chiefly in the interests of the public exchequer. The result of such fortuitous legislation has been unfortunate, and nowadays a child or other unauthorised person experiences no difficulty in obtaining an almost unlimited quantity of some of our most active poisons. In proof of this statement Dr. Hubbard says: "I made an expedition, accompanied by a child under twelve years of age, into a region of shops. I sent her alone into grocers' oilmen's, linendrapers', and other stores, where intimations existed that 'patent medicines' were sold. Without hesitation or inquiry of any kind, this child was supplied with any quantity of chloral or chlorodyne and other articles she asked for, and in a short time we returned home largely supplied with various poisonous drugs and compounds of deleterious and lethal substances. Had we extended our journey onwards with the same object, this little child could have procured sufficient poisons to have converted any parish in London into a city of the dead." It is estimated that there are now in this country nearly twenty thousand holders of patent medicine licences, of whom at least half are not chemists, and have no knowledge of medicine or pharmacy of any kind. During the year 1880-81 duty was paid by stamps on not less than 16,627,131 packages of patent medicine. Probably the most dangerous and insidious of all patent medicines are those containing chloral. It generally happens that the victim's attention is attracted by some skilfully worded advertisement of the miraculous effects of medicine bearing the "Government stamp," and to be obtained "of all respectable chemists, oilmen, and grocers." The effect of the first dose surpasses expectation, and another dose on the next occasion is equally satisfactory. No dangerous effects being indicated on the label, no danger is suspected; it is resorted to again and again, and by degrees becomes a nightly necessity. After a time the customary result is not experienced, "and not unfrequently in the middle of the night, by familiarity become bold, the *habitué*, after hours of weary tossing, with trembling hand pours out another half-teaspoonful or a few more drops, as the label directs, and drinks it off. The desired effect, and *more*, is now produced: coma ensues for sixteen, twenty, or even more hours, greatly to the alarm of surrounding friends; and not unfrequently the consequences

are such as to necessitate the services of the coroner." There is no subject connected with the health and welfare of our nation which requires more thorough and searching investigation and more prompt and stringent legislation than restrictions to the sale of deadly poisons.

### THE DRAINAGE OF BRIGHTON.

IN another column we print a letter addressed to us by Mr. Robert Rawlinson, C.B., of the Local Government Board, on the above subject. The opinion expressed by this authority is one with which the common-sense judgment of all who really desire the prosperity of "London-on-the-Sea" must coincide. A grave mistake has been made in regarding what we have done and said in this matter as prompted by feelings and wishes other than those of goodwill to the town and neighbourhood whose sanitary condition we have felt bound to criticise. Happily for the resident populations of other towns, our counsels are not wont to be treated as Brighton has treated them. The issue now lies before a legal tribunal, but we think it right to publish the letter to which we now direct attention, because it is a representative specimen of the communications we are almost daily receiving, and which show only too clearly the error of policy into which the ratepayers of Brighton have fallen.

It is fair to the town we have criticised to reproduce the following passage from a speech by the mover of the resolution recently passed by the Town Council. It proves that the combined effect of our remonstrances and Sir Joseph Bazalgette's "eminently satisfactory" report has been to stir the authorities to action:—

"They were now erecting ventilating shafts at the sides of houses to relieve the sewers of any gas which might be generated, and he would take that opportunity of asking owners and occupiers to bring common sense to bear on the question and assist the Council by giving permission to erect such shafts. The whole question with regard to sewer gas, so far as he could learn, rested on the temperature of the sewers. If they lowered this to a certain point there was no generation of sewer gas; and the question was how to do it. They had had the advice of Sir John Hawkshaw, Mr. Rawlinson, and Sir Joseph Bazalgette upon the ventilation of sewers in the streets, but in addition to that they were asking to ventilate by shafts at the sides of houses, and if they sufficiently ventilated the sewers they would do away with sewer gas to a large extent."

### STAMPING-OUT SMALL-POX.

ATTENTION has been drawn to a practice which is being adopted in Leicester with a view of "stamping-out" small-pox, the town being referred to as one where there are more prosecutions for non-compliance with the vaccination laws "than in all the other towns of England put together," and the practice is stated to excite great interest in medical circles. Directly a case of small-pox is heard of under the provisions of a local Act requiring the notification of infectious diseases, arrangements are made not only for the isolation of the person attacked, but also for the removal to the borough infectious hospital of all persons who live in the same house or have come into contact with the patient, these persons being subjected to a species of quarantine, during which they can be kept under supervision and their homes can be disinfected. The plan, it is alleged, is thoroughly successful, and this in a town where vaccination is notoriously neglected. The experiment is, however, by no means a novel one; and although there can be no doubt that there are distinct advantages in adopting it wherever it is practicable, yet it would be wrong to draw the inference that such action can be looked upon as sufficing to stay the infection of small-pox in a badly-vaccinated community. The Leicester health reports since 1879 show that the few attacks of small-pox which have occurred during the past three

years have been successfully arrested, although the isolation carried out appears to have been limited to the persons attacked, and hence we doubt if any sufficient experience has been acquired with regard to the quarantine system as would suffice for the formation of an opinion as to its general applicability to an ordinary population. Indeed there is no power by which a sanitary authority can compel the removal to hospital of any but the actually sick, and, even where such removal is voluntarily submitted to, there are no legal means by which such an authority can compensate persons who are thus compelled for a time to discontinue their ordinary avocations. Excellent as the practice may be under the circumstances of Leicester, and wherever it is found to be practicable, we cannot but regard its application as being very limited. We would therefore urge that the efficient vaccination and revaccination of the public generally are far more efficacious protections against small-pox than the mere isolation of the few who are known to have come into contact with infection, and we feel that in the long run it will be far safer to rely on a strict compliance with the provisions of the Vaccination Acts than on a system which may at any moment fail by the refusal of persons to subject themselves to it.

#### HOSPITAL ACCOMMODATION IN THE NORTH OF LONDON.

WE are glad to see that the Great Northern Hospital is alive to its responsibility in connexion with the general demand for a larger hospital accommodation in the north of London. "A meeting to consider the position of this hospital, and the need of increased hospital accommodation for North London," is to be held in the Athenæum, Highbury, on Wednesday, the 19th inst., and will be presided over by Lord Cowper, an ex-president of the hospital. It certainly does seem as if the Great Northern Hospital only wanted to be transferred to a better site, and reconstructed on a larger scale, to meet the wants of North London. Whether its representatives have the power of gathering into one focus all the energy that is now abroad in this cause remains to be seen. We hope the result will show that they have. At any rate, the Great Northern comes before the public with a good claim and with a good chairman, and we shall regard the meeting of the 19th with much interest.

#### THE MURDER OF KENNY IN DUBLIN.

THE following were the results of the post-mortem examination in reference to the injuries received by the deceased, who was assassinated in Seville-place last week. In addition to six wounds inflicted by a cutting instrument, and which were of little importance, four bullet wounds were found. One penetrated the left shoulder, passing upwards and inwards under the bone, the bullet lodging in the back of the neck. There were two on the back of the skull: one passed into the bone, from which it glanced downwards into the muscles at the back of the neck, where it was found close to the right ear; while the other penetrated the skull and passed in through the brain, tearing the right posterior lobe and the front left lobe. The fourth bullet wound was under the left arm, and had entered between the sixth and seventh ribs, penetrating the left lung; it then passed through the right lung out to the fifth rib through the muscles, broke the angle of the right scapula, and finally lodged in the muscles of the back. By this last bullet the aorta was penetrated, and a large quantity of blood filled the right pleural cavity.

#### METROPOLITAN HOSPITAL SUNDAY FUND.

THE amount collected for this fund has already reached £32,625. Many contributions have yet to come in, including that of Kensington parish church.

#### OPENING THE ŒSOPHAGUS.

AN opportunity has recently occurred at the London Hospital to test the correctness of the views advocated by Mr. Reeves in a paper on gastrostomy read at a late meeting of the Clinical Society. A man, aged sixty, under the care of Dr. Stephen Mackenzie, was referred to Mr. Reeves on account of malignant obstruction of the Œsophagus, and as Dr. Mackenzie and Mr. Adams concurred with Mr. Reeves as to the advisability of a cervical incision, the operation of Œsophagotomy was undertaken and successfully completed. It was difficult to recognise the Œsophagus, whose walls were cancerous, and on account of their friability the attempt to secure it to the skin was abandoned and a large elastic catheter was introduced and tied in. A complete account of this unusual and surgically important case will appear when all details are complete, but in the interim the attention of surgeons is drawn to it because it serves to dispel the belief which has hitherto existed in the professional mind as to the danger and difficulty of the operation when undertaken for stricture.

#### REMARKABLY LOW DEATH-RATES.

DR. JACOB recently presented to the Rural Sanitary Authority of Chertsey his annual report for 1881, which affords the strongest evidence of the satisfactory condition of this sanitary district, notwithstanding the local prevalence of scarlet fever in some of the parishes. The aggregate population of this district is now not far short of 30,000 persons, and the death-rate last year in some of the nine parishes constituting the union and rural sanitary district was exceptionally low; it was only 13.3 in Chertsey, 12.8 in Walton, and 11.5 in Weybridge. The highest parish rate during the year was 17.7 in Chobham, and even this scarcely exceeds the mean rate for such districts according to Dr. Farr's Healthy District Life Table. Dr. Jacob expressed the hopeful conviction that the prejudices which had stood in the way of the due utilisation of the hospital for infectious diseases are now nearly overcome.

#### SUMMER DIARRHŒA.

THE recent unseasonably cold and wet weather has hitherto repressed the usual increase of diarrhœa fatality at this season. In London the deaths referred to diarrhœa, principally infantile, which had been 32 and 41 in the two previous weeks, rose to 73 in the first week of July, but were no fewer than 42, or 37 per cent., below the corrected average number in the corresponding week of the last ten years. These 73 deaths were equal to an annual rate of 1.0 per 1000. In the twenty-seven provincial towns embraced by the Registrar-General's Weekly Returns, with an aggregate population somewhat exceeding that of London, the deaths attributed to diarrhœa were 67, equal to a rate of 0.8 per 1000. The highest death-rates from diarrhœa in these provincial towns last week were 2.9 in Bolton and 1.7 in Leicester.

#### HEALTH OF HOVE.

THE Medical Officer of Health for Hove, an urban sanitary district adjoining the borough of Brighton, and forming an integral part of that town, has just issued his report for the quarter ending June 30th last. The population of the parish and sanitary district is estimated at 21,000 persons, and the annual death-rate during last quarter is reported to have been only 13.2 per 1000, while the zymotic death-rate in the same period was equal to 1.6 per 1000. It is, moreover, stated that no death during the quarter was referred either to typhoid fever, scarlet fever, or diphtheria.

THE President of the Local Government Board has appointed Dr. Frederick W. Barry to be one of the medical inspectors of the Board, in the place of Dr. Beard, who has resigned. Dr. Barry for several years held the appointment of medical officer of health for the combined sanitary authorities in the Craven district, in the West Riding of Yorkshire, and during that period he distinguished himself, both in his work and in his reports, as an active and able officer. He was later on appointed to be Chief Medical Officer and Sanitary Commissioner to the Government of Cyprus, and in the numerous duties which devolved upon him there he gave further evidence of his ability in administrative work.

MR. E. G. SCOTT, Colonial Medical Officer stationed at Port Louis, Mauritius, states that in the cases of gangrene resulting from fever, so common in the island, he has found a superficial incision into the skin around the sphacelus succeed better than anything else in limiting the sloughing process and in hastening the separation of the slough.

AT a meeting of the Council of the Poor-law Medical Officers' Association, held at their rooms, 3, Bolt-court, Fleet-street, on the 6th inst., it was resolved that the annual meeting of the Association should be held at Worcester during the meeting of the British Medical Association.

THE report of the Committee on the Contagious Diseases Acts is expected to be ready for consideration on the 27th inst. The evidence is very voluminous, no fewer than forty thousand questions having been put to the various witnesses.

MESSRS. LIPPINCOTT, of Philadelphia, announce the forthcoming appearance of a work entitled "A Treatise on the Physiological and Therapeutical Action of the Sulphate of Quinine," by Dr. F. Otis Manson.

WE understand that Dr. Joseph Coats, of Glasgow, has in preparation a Text-book of Pathology, including General Pathology and Pathological Anatomy.

WE are asked to state that the museum of the Royal College of Surgeons will be closed from August 1st till further notice, in order that it may undergo the necessary repairs.

THE small-pox epidemic at Cape Town is reported to be assuming larger proportions.

## Public Health and Poor Law.

### LOCAL GOVERNMENT DEPARTMENT.

#### REPORTS OF INSPECTORS TO THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

*Sherborne (Enteric Fever).*—In 1873 a widely spread and fatal epidemic of enteric fever took place at Sherborne, in Dorsetshire, and it was shown by Dr. Blaxall, of the Local Government Board, to be due to the direct communication which then existed between waterclosets and the town water-mains, an arrangement which, during intermissions in the water service, had led to the forcible suction of foul air into the mains. Early this year Sherborne was again visited by a prevalence of this disease, and although in this instance the outbreak was localised and on a much smaller scale, yet it has been ascertained to have been due to very similar circumstances. Some of the attacks occurred where the

admittedly excellent supply of town water was laid on, but in these cases the drinking water was derived from cisterns which not only supplied waterclosets, but which, through their overflow-pipes, were also to some extent subject to the risk of pollution. Indeed, chemical analysis indicated that by one or other of these methods the cistern-water had become to some extent contaminated. Special interest centres, however, in one group of houses where several cases occurred, and to which an independent water-supply was delivered through a main which also supplied water to the water-closets without the intervention of cisterns. The contents of the main were thus brought into direct communication with any foul effluvia rising from the closetpan or forced up from the sewer, which at the time had received specifically poisoned evacuations. Many important sanitary improvements had been carried out in Sherborne after Dr. Blaxall's first visit, but the principal faulty condition then pointed out had been allowed to remain in this group of houses, the result being that it was specially seized on by the disease in question. Since the original Sherborne epidemic occurred, and the remedy for it was pointed out, other towns having intermittent water services, and having the supply to water-closets laid on direct from the mains, have also suffered in a similar way from outbreaks of enteric fever; and yet Sherborne had not sufficiently profited by the lesson to rid the town of all such dangers. Hoping that other towns may take heed in time, we would again urge upon sanitary authorities the extreme importance of insisting upon the service to waterclosets being invariably delivered through the intervention of a cistern, so as to secure a complete break between the interior of the closetpan and the water main, and further, of seeing that no water for domestic purposes can ever be drawn from the cisterns supplying waterclosets.

*Holywell (Sanitary State).*—Holywell, an old market town in Flintshire, was officially inspected in 1875 on account of the prevalence of scarlet fever and other epidemic disorders. A severe outbreak of diphtheria occurred there in 1878 in association with defective sanitary conditions, and the general death-rate for the last five years has been at the rate of 23.5 per 1000, as compared with a rate of 21.0 for England and Wales. Early this year the town was again visited by Dr. Franklin Parsons of the Local Government Board, who states that, with regard to the conditions calculated to affect health injuriously, the state of matters described in 1875 remains substantially the same. Holywell stands at the head of the ravine down which flows the stream proceeding from St. Winifred's Well, a remarkable spring said to yield at the rate of 100 tons a minute, and which is resorted to for bathing on account of its supposed healing virtues. Others, therefore, than the ordinary residents are unfortunately interested in the sanitary condition of the district. But Holywell is "decaying"; its population has decreased from 3540 in 1871 to 3091 in 1881; only one new house has been built for twenty years; and the cost of adopting effective sanitary measures and administration would probably ruin the place. And Holywell by no means stands alone in this respect; for the country is dotted here and there with urban districts far too small and too sparsely populated to be capable of bearing the cost of the sanitary works which are necessary for their well-being. Such districts should be done away with as separate sanitary areas, and they should be again included in the rural districts from which they once emerged. Dr. Parsons, indeed, hints in his report that such a course is the only practicable one to relieve Holywell of its present sanitary disadvantages.

#### REPORT OF MEDICAL OFFICER OF HEALTH.

*Portsmouth (Urban).*—The main interest in Dr. Walter J. Sykes' report upon the sanitary condition of the borough of Portsmouth during 1881 centres in the remarkable epidemic of diphtheria from which the town suffered throughout the year. The birth-rate was equal to 34.2 per 1000; it was higher than in any previous year since 1873, and was 1.1 above the mean rate in the ten years 1871-80. The death-rate was 19.6, which, although showing an increase upon the low rates in recent years, was 2.1 per 1000 below the mean rate during the year in the twenty large towns dealt with in the Registrar-General's weekly return. The death-rate from the principal zymotic diseases was equal to 3.4 per 1000, and corresponded with the mean rate in the twenty towns. The zymotic death-rate in the borough exceeded that recorded in any year since 1876, when scarlet fever was severely epidemic. The low death-rate from dis-

cases other than zymotic was fully as remarkable last year as in recent years. Dr. Sykes, in reporting that 205 fatal cases of diphtheria were recorded during the year, remarks that "such a serious epidemic of this disease seems to be unprecedented in the annals of Portsmouth." Diphtheria fatality was exceptionally quiescent in Portsmouth during the three years 1877-8-9, and in the first half of 1880, whereas the recent epidemic broke out in the autumn of that year. It is to be regretted that the causation of this remarkable epidemic receives little or no elucidation from Dr. Sykes' report, most of the information there given being mainly of a negative character, excepting only the expressed conviction that the public elementary schools played an important part in the distribution of the disease. The evidence adduced seems to prove that the disease spread by personal contagion rather than by the distribution of the contagium by means of the sewer system, or of the water or milk supply. It would seem that nothing short of prompt notification of the cases of attack, and a systematic removal to hospital of all cases in which house isolation was impossible, would have repressed this fatal epidemic. The interesting and important question, however, still remains unanswered, Why did diphtheria become so fatally epidemic in Portsmouth last year, while in other towns, in all of which sporadic cases occur from time to time, the disease did not assume an epidemic character? It appears that only 27 cases of diphtheria were admitted to the infectious diseases hospital during the year, of which 8, or nearly 30 per cent., proved fatal. Dr. Sykes speaks hopefully of a "large sphere of usefulness for the new hospital" for infectious diseases, and expresses a belief that hospital isolation is gaining in popularity. The tables in this report give much that is valuable in the way of statistical information, but we regret to see no attempt to assimilate the forms of any of the tables to those adopted in any of the other annual reports for large urban sanitary districts. We notice, too, that no attempt has been made to correct the statistics for years prior to 1881 for errors in the estimates of the annual population in use up to the date of the recent census. One of the results of this oversight is an apparent reduction (Table I.) of nearly six thousand in the population of the borough between 1880 and 1881. We need scarcely point out that the population of the borough is not declining, or that the birth- and death-rates for the ten years 1871-80, republished by Dr. Sykes (Table II.), are all more or less fallacious on account of these errors in the estimated population. The value of such reports is much increased by a map. Dr. Sykes' map, however, would be improved if the boundaries of the borough, and the registration subdistricts, or other statistical subdivisions of the borough, were marked thereon.

### VITAL STATISTICS.

#### HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns, 5620 births and 2984 deaths were registered during the week ending the 8th inst. The annual death-rate in these towns, which had been equal to 19.1 and 18.1 per 1000 in the two preceding weeks, was 18.4 last week. The mean rate during last quarter was 20.9, against 20.4 and 20.5 in the two previous corresponding periods. The lowest rates in these towns last week were 13.5 in Norwich, 14.4 in Derby, and 15.1 in Bristol. The rates in the other towns ranged upwards to 22.5 in Huddersfield, 23.2 in Manchester, and 24.8 in Nottingham. The deaths referred to the principal zymotic diseases in the twenty-eight towns were 470, showing a further slight increase upon recent weekly numbers; 140 resulted from diarrhoea, 125 from whooping-cough, 69 from measles, 63 from scarlet fever, 29 from "fever," 20 from diphtheria, and 14 from small-pox. The lowest death-rates from these diseases occurred in Cardiff and Halifax, and the highest in Portsmouth and Nottingham. Whooping-cough was proportionally most fatal in Bristol and Birkenhead; measles, in Huddersfield and Birkenhead; scarlet fever in Nottingham and Wolverhampton; and "fever" in Portsmouth. Of the 20 deaths from diphtheria in the twenty-eight towns 16 occurred in London. Small-pox caused 8 deaths in London and its suburban districts, 4 in Birmingham, 3 in Nottingham, and one in Manchester. The number of small-pox patients in the metropolitan asylum hospitals, which had steadily declined in the ten preceding weeks from 350 to 233, further fell to 214 on

Saturday last; 30 new cases of small-pox were admitted to these hospitals during last week, against 44 and 29 in the two previous weeks. The deaths referred to diseases of the respiratory organs in London, which had been 198 and 212 in the two previous weeks, declined to 173 last week, and were 25 below the corrected weekly average. The causes of 64, or 2.1 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Wolverhampton, Derby, Birkenhead, Manchester, and Preston; while the proportions of uncertified deaths were largest in Hull and Leeds.

#### HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which had been equal to 22.4 and 21.9 per 1000 in the two preceding weeks, further declined to 20.5 in the week ending the 8th inst.; this rate, however, exceeded by 2.1 the mean rate last week in the twenty-eight large English towns. The deaths referred to the principal zymotic diseases in these Scotch towns were 91 last week, and showed a decline of 9 from the number in the previous week; they included 38 from diarrhoea, 20 from whooping-cough, 10 from diphtheria, 9 from "fever," 7 from scarlet fever, and 7 from measles. The 38 deaths attributed to diarrhoea were 11 above the number returned in the corresponding week of last year; 19 occurred in Glasgow and 9 in Dundee. Diarrhoea was proportionally more fatal last week in the Scotch than in the English towns. The 20 fatal cases of whooping-cough were 5 fewer than those in the previous week, and included 12 in Glasgow and 4 in Edinburgh. The 10 deaths referred to diphtheria corresponded with the number in the previous week; 4 were returned both in Glasgow and Edinburgh. It is noticeable that Dr. Littlejohn in his weekly return only reports one fatal case of diphtheria in Edinburgh last week, instead of the 4 reported by the Registrar-General. It would appear from Dr. Littlejohn's letter, in another column, that the classification of diseases for the Registrar-General's returns is not always entirely trustworthy. The 9 deaths from "fever" in the eight towns were 3 fewer than in the previous week, and included 4 in Glasgow and 3 in Edinburgh. The 7 fatal cases of measles included 4 in Dundee and 2 in Aberdeen; while 3 and 2 of scarlet fever were respectively returned in Glasgow and Edinburgh. The deaths referred to acute diseases of the lungs in the eight towns, which had been 111 and 97 in the two preceding weeks, further declined to 92 last week, although they exceeded by 5 the number attributed to these diseases in the corresponding week of last year.

#### HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 23.2 and 20.7 in the two preceding weeks, further declined to 20.5 in the week ending the 8th inst. During the thirteen weeks of last quarter, however, the death-rate in the city averaged 26.8 per 1000, against but 19.5 in London and 20.5 in Edinburgh. The 137 deaths in Dublin last week showed a further decline of one from recent weekly numbers, and included 6 which were referred to fever, 5 to diarrhoea, 3 to scarlet fever, and not one either to small-pox, measles, diphtheria, or whooping-cough. Thus 14 deaths resulted from these principal zymotic diseases, corresponding with the number in the previous week; these 14 deaths were equal to an annual rate of 2.1 per 1000, against 3.4 in London and 8.8 in Edinburgh from the same diseases. The 6 deaths referred to "fever" exceeded the numbers in the two previous weeks; while the 5 deaths attributed to diarrhoea corresponded with the number in the previous week. The 3 fatal cases of scarlet fever exceeded the number returned in any week since March last. The deaths of elderly persons showed a considerable decline from recent weekly numbers, as did also the number of uncertified causes of death.

#### MORTALITY STATISTICS OF TRINIDAD.

A report recently addressed by the Registrar-General of Trinidad to the Colonial Secretary gives just enough facts concerning the vital statistics of this West Indian island to make us wish for further information. It appears that the population of the island at the last census was 153,128, and that during last year the births were equal to a rate of 35.2,

the deaths 32.7, and the marriages only 3.7 per 1000 of that population. We are told that the birth-rate showed a small increase, while the marriage-rate had considerably decreased. Considering the excess of the death-rate, the baldness of the Registrar-General's report upon the mortality is disappointing. The tables show, it is true, the number of deaths in the different subdivisions of the island, but no clue is given to the population of these several subdivisions, so that the bare numbers given are entirely devoid of interest or utility to the statistician. Not a figure is given bearing upon either the causes of death or the ages of the decedents. The Registrar-General says: "The large increase of deaths is evidently attributable to some cause of an unusual character, and this is found to arise in some measure from the late fever." It is suggested that but for this "fever" the death-rate would probably not have exceeded that which prevailed in the previous year, which was 26.9 per 1000; but not a word is added as to the nature of the fever or its local distribution, although the disease would appear to have caused nearly 900 deaths. The report has been laid before Council in obedience to an Ordinance bearing date in 1847, and it therefore seems probable that these reports have been presented for some years, in which case it is much to be regretted that the report contains no summary of the statistics for a series of years. It is quite time that some attempt should be made to secure more uniformity in the reports on the vital statistics of our various colonies. All such reports should contain, at any rate, a minimum number of uniform tables.

#### CENSUS REPORTS: COUNTY ANTRIM.

The population of this county in 1881 amounted to 421,943, being an increase of 4.4 per cent. over the previous decade. There was an increase in the number of those receiving poor law relief as compared with 1871. For example, in 1871 the number was 4761, or 1 in every 85 of the population (3811 in-door and 956 out-door), while in 1881 the total was 6320, or 1 in 67 (4445 in-door and 1875 out-door). The average annual rate of mortality was 21.0 per 1000, the corresponding rate for the whole of Ireland being 18.3; the number of births registered during the ten years was 125,189, and the number of deaths 86,592. A natural increase of 38,597 would thus appear to have taken place in the population, but the emigrants during the same period having amounted to 59,431 the net result shown is a decrease of 20,834, whereas an increase of 17,930 is exhibited by the census returns, a disparity to be accounted for by immigration, of which no record is obtainable.

#### THE SERVICES.

Surgeons Irving and Lewis embarked on board H.M. troopship *Malabar* on the 8th inst., in charge of the troops proceeding to Gibraltar.

Deputy Surgeon Generals A. C. De Renzy, C.B., and S. Townsend, C.B., Bengal Medical Service, have been selected for good service pensions by the Government of India.

ARMY MEDICAL DEPARTMENT.—Deputy Surgeon-General John Gibbons, C.B., has been granted retired pay, with the honorary rank of Surgeon-General.

RIFLE VOLUNTEERS.—5th Devonshire: William Henry Webb, Gent., to be Acting Surgeon.—1st Dumfries: Acting Surgeon Alexander Dale Macdonald, M.D., to be Surgeon.—1st Durham: Surgeon John Farquharson resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the Corps on his retirement.—2nd Glamorgan: Acting Surgeon John Llewellyn Trehearne resigns his appointment. Frederick William Evans, Gent., M.D., to be Acting Surgeon.—15th Middlesex (the Customs and the Docks): Surgeon Robert Gordon Tatham is granted the honorary rank of Surgeon-Major.

ADMIRALTY.—Fleet Surgeon Matthew Coates has been placed on the Retired List, with permission to assume the rank and title of Retired Deputy Inspector-General of Hospitals and Fleets in Her Majesty's Fleet.

The following appointments have been made:—Fleet Surgeon James F. Parr, to the *President* (additional), for temporary service; James Hunter, M.B., Surgeon and Agent, at Queensferry, vice Dewan; Staff Surgeon Matthew Fletcher Ryan, to the *Familiars*, vice Edward T. Lloyd; Surgeon Richard G. Brown, M.B., to the Portsmouth Division of the Royal Marines, vice Lucas.

#### ASSOCIATION FOR THE ADVANCEMENT OF MEDICINE BY RESEARCH.

A MEETING of the Association for the Advancement of Medicine by Research took place at the Royal College of Physicians, on Wednesday, the 12th inst. There were present Sir James Paget (in the chair), Sir Risdon Bennett, Sir Joseph Fayrer, Dr. Andrew Clark, Mr. Bowman, Professor Humphry, Cambridge; Professor Michael Foster, Cambridge; Dr. Samuel Wilks, Mr. Lister, Professor Gamgee, Manchester; Dr. Burdon Sanderson, Dr. Balthazar Foster, Birmingham; Dr. Lauder Branton, Professor Gerald Yeo, Dr. Pye-Smith, Dr. Payne, Dr. Matthews Duncan, Sir Henry Thompson, Dr. Buchanan, Dr. B. Barrow, Ryde.

The Treasurer reported that he had received from Sir Wm. Mac Cormac £300 from the surplus funds of the International Medical Congress, and that the funds of the Association now exceeded £1200.

The Secretary reported that many eminent men in the provinces had consented to act as corresponding members, and that branch committees were being established in some of the principal towns.

The Executive Committee recommended that, as a first step in the direct promotion of research, Mr. Watson Cheyne should be requested to undertake the verification of the results lately obtained by Koch on the subject of tuberculosis, and the comparison of these with the results obtained by Toussaint and other observers.

The following resolution was proposed by Dr. Burdon Sanderson, seconded by Dr. Barrow, of Ryde, and carried unanimously: (1) "That the Council approve the recommendation of the sub-committee to raise funds for the payment of competent persons engaged in researches in medical science; that they regard the subject selected (tubercle) as peculiarly eligible, and sanction the expenditure recommended." It was proposed by Professor Lister, seconded by Professor A. Gamgee, and carried unanimously: (2) "That the Treasurer be requested to issue a circular asking for subscriptions or donations for the object of the first resolution, and that the corresponding members be requested to further this effort."

The Executive Committee reported that they had selected several papers explanatory of the methods and objects of scientific research in physiology, pathology, and therapeutics, and recommended that they be reprinted. They also mentioned that some papers which they desired to reprint, having appeared in certain journals the rules of which did not allow reprinting until a year had elapsed from the appearance of the papers, they had been obliged to defer the reprinting of these papers.

It was proposed by Sir Risdon Bennett, seconded by Sir Henry Thompson, and carried unanimously: (3) "That the Council authorise the publication of the various pamphlets and papers selected or to be selected by the Executive Committee, and direct that they be distributed as widely as possible by the corresponding or ordinary members of Council, and also sold in such manner and at such prices as the Executive Committee may determine."

The Executive Committee reported that communications with the Home Office had led to what promised to be a more satisfactory arrangement with regard to the issue of licences and certificates under the Act 39 and 40 Vict., cap. 77.

It was proposed by Sir Joseph Fayrer, seconded by Dr. Balthazar Foster, and unanimously carried: (4) "That the Council congratulate the Executive Committee on the promising results of their representations to the Home Office, and begs them to continue their efforts in the same direction."

The Executive Committee reported that effectual steps had been taken for meeting the Bill for the Total Abolition of Scientific Experiments on Animals, which was down for the second reading on the 21st of June last. The pressure of public business had prevented the Bill being discussed, but it had been useful in showing the strong support which

medical science may count on in the House of Commons. A memorandum, which had been prepared for this occasion, setting forth the necessity and utility of experiments in physiology, pathology, and therapeutics, was laid before the Council and discussed.

It was proposed by Dr. Matthews Duncan, seconded by Sir Risdon Bennett, and unanimously carried: (5) "That the memorandum as amended be distributed, with the sanction of the Council, among Members of Parliament or others who are interested in the advancement of Medical Science."

## Correspondence.

"Audi alteram partem."

### THE FIRST YEAR'S EXAMINATION IN ANATOMY AND PHYSIOLOGY.

To the Editor of THE LANCET.

SIR,—I gather, from conversations held during the past few days, that the large majority of the members of the various hospital staffs are not aware of the real character of the first year's examination proposed by the Royal College of Surgeons. The College desires that an examination in anatomy and physiology shall be held at each school at the end of the first winter session, and will not admit any student to the first College examination until six months after he has obtained a certificate of having passed the first year's examination. The lecturers on anatomy and physiology, who were summoned to a meeting at the College, were told that the Council wished to strengthen their hands in holding the sessional examinations which have been instituted at most schools during the last few years. At first sight the scheme appears harmless, and the object good. Probably on this account it has attracted much less attention than it deserves. But a careful consideration shows that it involves an entirely new principle, and a serious departure from the custom of the schools. For this examination is, to all intents and purposes, a qualifying examination for the M.R.C.S., and is to be held, not by the College examiners, but by the hospital teachers of anatomy and physiology. It is as certainly a qualifying examination as any now held by the College of Surgeons, inasmuch as a student cannot obtain his diploma without passing it, and it will cast upon the teachers of anatomy and physiology, in certain cases, the responsibility of excluding students from the profession. It behoves the schools to consider seriously whether they will permit their teachers of anatomy and physiology to accept this responsibility. I confess I can scarcely see any reason why they should do so, while I can find many reasons why they should not.

First, the business of the schools is to teach, and not to examine for diplomas.

Second, it is very undesirable that the schools should be placed under the control of any licensing body.

Third, if the schools undertake to hold an examination in certain special subjects for one licensing body, they may fairly be required to hold examinations in special subjects for all the licensing bodies.

Fourth, it is not proposed to remunerate the schools or the teachers for the trouble and responsibility of holding repeated examinations in anatomy and physiology on behalf of the College.

I have been told that the College will leave the "first year's examination" entirely in the hands of the school authorities, who may make it as easy or as difficult as they choose. Can any worse argument be used in favour of it? It may be easy in one school, difficult in another: it may be very unequal for different students in the same school; it may be a farce or a very disagreeable reality. From one or other of these causes complaints will soon be numerous and urgent, and who is then to guarantee that the College and the Medical Council will not insist on visiting the examination, and practically changing it from a private into a public ordeal. That the College, deeming a "first year's examination" necessary, should be pleased with this scheme is perfectly intelligible, for it will save them the expense and trouble of conducting it. But why the teachers of anatomy and physiology should have accepted it is incomprehensible.

Fortunately, the teachers of anatomy and physiology do not constitute the schools, whose opinion of the scheme has not been sought. It will, however, probably be given unasked; and if it be adverse, the College will scarcely care to push its authority so far as to force this examination on the schools.

I remain, Sir, yours obediently,

Queen Anne-street, W., July 10th, 1882. HENRY T. BUTLIN.

### DESTRUCTIVE OPHTHALMIA.

To the Editor of THE LANCET.

SIR,—As ophthalmia is endemic in Egypt, I think it may be useful to draw the attention of my brother officers ordered there to a terribly destructive form of that disease which assailed us in Ceylon, and of which I have never been able to find any description in the usual text-books, though, no doubt, the dusty archives of the Army Medical Department contain information on that and many other items of valuable experience, buried (upon our blessed system) and useless to the successors of those who laboriously gained it, leaving them to work in the dark and learn for themselves at the expense of unfortunate patients. The form of disease in question manifested itself at the season of intensely hot and glaring days, followed by cloudless cold nights, just what is likely to be met with in Egypt. A man would appear in the morning sick, report with what looked an ordinary smart attack of simple conjunctivitis; by evening visit the eyelid affected would be found greatly swollen, almost as dark as a piece of liver, extending far down on the cheek, hiding the globe completely, while from beneath it flowed a thick puriform discharge; the pain in the eyeball being described as excruciating, and such as to prevent any sleep. Next morning the man would relate that he had so remained, suffering acutely, till long past midnight, when all at once he fancied something like a "gathering" broke, a great flow of hot fluid followed, and he experienced immediate and continued relief, so that he would tell his little history with great satisfaction, and fancy his eye was on the high road to recovery. Some days would elapse before the subsidence of swelling allowed one to see the globe, and then it would be found the cornea had burst, and the poor fellow's sight was gone for ever! Some unfortunates lost both eyes in this way, to my intense regret and mortification. Having been a pupil of old Jacob's, and having emptied eye wards handed over to me full, I had rather a good opinion of my skill in that line till the disease I have described presented itself and defied all the recognised methods of treatment. No abstraction of blood, either local or general, relieved it; the use of nitrate of silver and all other collyria seemed, to say the least, quite useless, if no worse. Fomentations and the injection of tepid solution of muriate of ammonia beneath the lids gave some relief; but the real severe cases, if they did not end by altogether destroying vision, seldom left a useful, perfectly sound eye after them. The trouble, worry, and annoyance that this outbreak gave, even in quiet cantonments, were very great; but how much worse would they be on service in Egypt! The moral of my story is, that rather too late in the day I found out that full doses of quinine and of opium were the proper remedies for this horrible ophthalmia, it being apparently caused by the malarious poison which shows itself in so many protean forms; and I hope that this dearly bought experience may now be of use to my younger brethren whose troubles are all before them.

I am, Sir, yours truly,

Junior United Service Club, July 8th, 1882. J. C. CAMERON.

### ANÆSTHETICS.

To the Editor of THE LANCET.

SIR,—I can fully confirm Mr. Bendelack Hewetson's observations as to the superiority of methylated ether as an anæsthetic over that made with rectified spirit. The trial of it was suggested to me some two years ago by our analytical chemist here, Mr. Young, on the ground that as it was more volatile it would probably act quicker and safer as an anæsthetic. These conditions I have found fulfilled, and laryngeal spasm and troublesome sickness have seldom occurred.

Shortly after the adoption of the methylated ether by my colleagues and myself at the Infirmary, Clover's inhaler was introduced; and we calculate etherisation costs the Infirmary now 3s. 4d. less than formerly. In order to ensure obtaining the right article I would advise my readers to ask for “absolute methylic ether, specific gravity ‘717,” as ordinary methylated ether is an abominable and unsuitable compound.

As regards deaths from ether, I make no doubt many occur which are never reported, for the simple reason that the death, instead of being instantaneous (as in the case of chloroform), occurs some hours later from bronchitis. At any rate, there have been two such deaths from ether at the Leicester Infirmary during the last nine years, against two from chloroform in the same period. I have felt it my duty to put this statement in print, as there is a growing tendency to hold a man guilty of homicide if he has the misfortune to lose a patient from chloroform; whereas a careful examination of all deaths occurring within three days of the administration of an anæsthetic might show that ether is not so very much safer than our old friend chloroform.

I am, Sir, yours faithfully,

FRANK H. HODGES, F.R.C.S. Ed.

Leicester, July 5th, 1882.

*To the Editor of THE LANCET.*

SIR,—Your article on “Chloroform,” under date July 1st, once more calls the attention of our profession to the grave risk attendant upon the use of chloroform as an anæsthetic. I would at once put the question, Why use it when a far safer and more preferable agent is within reach? How many deaths would have been avoided had it been the universal practice to adopt Mr. Jonathan Hutchinson's golden rule—“Ether for all patients over six years of age and under sixty”? Does not this rule cover such cases as those recorded last week, and many others from time to time reported?

The history of the fatal case is practically the same. It is a young or middle-aged patient, in fair, or even robust health, who is about to submit to some minor but painful operation. Chloroform is administered; the first stage is protracted; in the second stage suddenly the pulse becomes weak, then stops; a few embarrassed attempts at respiration are made, and all is over. The horror-stricken attendants send galvanic shocks through the thorax, and vigorously perform artificial respiration, but all to no purpose. The autopsy reveals a healthy or slightly fatty heart, with uncontracted ventricles. Would all this have happened had ether been the anæsthetising agent employed? I venture to say emphatically, No. Ether stimulates instead of depresses the heart's action. Ether never caused the heart to fail in a young or middle-aged patient in fair or robust health. Why should chloroform then be used for such cases? Is it because, though acknowledged to be infinitely more dangerous, it is claimed to be more manageable and quicker in its action? This excuse does not hold good since Ormsby and Clover have placed in our hands their simple and efficient inhalers. Of the two I much prefer Ormsby's.

As house-surgeon to Mr. Jonathan Hutchinson, and house-physician to Dr. Palfrey, I had very great opportunities of testing various anæsthetising apparatus and agents. From an analysis of one hundred cases taken haphazard, where Ormsby's inhaler was employed, I find that complete anæsthesia is obtained in a shade under two minutes, and that the quantity of ether required is an ounce and a half for an operation lasting twenty-five minutes. The stage of excitement is very short. The secretion of mucus and consequent frothing about the mouth, and troublesome accumulation in the larynx, are reduced to a minimum.

The mask is so readily removed and replaced that operations about the mouth and nose are but little interfered with by the anæsthetiser. Since the Ormsby inhaler has been taken into general use at the London Hospital I am informed that the saving in ether has been enormous, and what I consider far more important is that chloroform is being gradually banished from the wards.

One word more and I have done. From my practice of the last six months I can fully endorse Mr. Hewetson's

remarks as to the advantages of ether prepared from methylated spirits. On the other hand, I have observed no disagreeable results from its use.

I am, Sir, yours, &c.

Duke-street, W., July 4th, 1882.

W. H. FENTON JONES.

*To the Editor of THE LANCET.*

SIR,—In sending you an account of the inquest on the unfortunate man who died during the administration of chloroform at the Kent and Canterbury Hospital, I beg to make the following remarks.

James S—, aged forty-nine years, had formerly been a butler and accustomed to excessive alcoholic indulgences. He was admitted on June 9th for caries of the right fifth metatarsal bone, which was preventing the union of a wound caused two months previously by the removal of the little toe. His left great toe had also been removed five years ago for disease. He looked somewhat feeble, but bore no physical signs of cardiac disease; his urine was normal and his appetite fairly good, though he did not eat all the meat of his “full diet.” After six days' rest in bed, chloroform was administered to him by the house surgeon in the ward, by means of a conical wire gauze inhaler covered with flannel, such as is used at St. Mary's. The patient breathed very quietly, but was slow in getting under the influence of the anæsthetic. I made one short quick incision down to the dead bone, and he said he felt it. Fresh chloroform was sprinkled from the drop-bottle on to the cone, after which the patient talked loudly in a drunken manner, struggled, and tried to sit up in bed; then his pulse fluttered, his face became livid, his jaw fell, his heart ceased to beat, he gave a few superficial and irregular sighing respirations, and all was over. The administration of the chloroform was stopped immediately the pulse fluttered. Artificial respiration, the tongue being drawn out, was at once resorted to, and a Stöhrer's battery was applied within two minutes, but the heart would not respond. The patient died within ten minutes from the commencement of the administration, which was most carefully conducted. The amount of chloroform used was nearly two drachms and three-quarters. The man was never fully under its influence, but died in the stage of excitement from sudden arrest of the heart's action.

Unfortunately the coroner did not order a post-mortem, and the friends would not give their consent to any examination of the body afterwards. Ether was the anæsthetic first employed at our hospital, and introduced there by my father; during the last thirty-two years chloroform has been administered (sometimes in various forms of inhalers, but chiefly on lint) with an interrupted success. For the last five years I have occasionally used ether again, in a Clover's inhaler, but chloroform has been given as a rule.

I am, Sir, yours truly,

Canterbury, June 21st, 1882.

T. WHITEHEAD REID.

**“DOCTOR OR DRUGGIST?”**

*To the Editor of THE LANCET.*

SIR,—I have no doubt that the letter of “M.D.” on this subject in your last week's issue will lead to some further correspondence, and that we shall have the pros and cons of the matter fully discussed. Whether or not “M.D.” has during the natural course of his professional life wandered over the face of the globe, or whether he has even settled down to general practice, is a matter not quite clearly to be made out from his letter, although one cannot but hope that the former has been the case, for I take it that, from a practical point of view, no more irrational or illogical letter on any subject has ever been before inserted in your valuable paper. If your correspondent had waged war against the “counter” or “open shop” practices in most of the towns of these isles, he would doubtless have had the whole body of the respectable men of our profession with him. If he had started an agitation against that now almost constant and universal practice of chemists prescribing for their customers, a general crusade against this formidable evil might have owed its origin to his pen. But how can he for one instant sit down and attempt to bring before the medical world the sweeping so-called medical reform—that no

respectable practitioner, under any circumstances whatever, should dispense medicine for his patients? What would become of those inhabitants of our numerous small villages, situated, as many are, some miles from a town where they could find a chemist to dispense a prescription given them by their medical man for some urgent case? "Oh," says your correspondent, "Dr. Apothecary Brown or Smith would be practising in such places." How could we expect the poorer classes, the artisans, or the mechanics to pay not only the doctor's charges for visits, advice, and prescriptions, but also the druggist's bill for medicines required for one of their children, say, during an attack of rheumatic fever? "Oh," says your correspondent, "Mr. Apothecary Brown or Smith would attend such as those!"

Again, how would the country general practitioner, who represents such a large proportion of our profession, fare if for all his club patients and his paupers, to say nothing of his other patients among the poorer classes, he had to make arrangements with some chemist to dispense all his prescriptions? "Oh," says your reforming correspondent, "Mr. Apothecary Brown or Smith would hold such appointments." So, Sir, the inhabitants of our hundreds and thousands of country villages are to be handed over to the tender mercies of men who are content with having passed the examination for a licence to act as an apothecary, and all other practitioners must search for new fields afar or betake themselves straight, with their wives and families, to the nearest union, there to be supported at their country's expense until the utter idiocy of such a reform were found out. These and numerous other difficulties rise up before me on reading such an effort to bring about what is considered by your correspondent as a necessary social reform. Anyone starting such an utterly unfeasible and impracticable theory should surely be prepared with the ways and measures necessary to carry such out, and unless he can conscientiously do so, I for one take it that he had better employ his time and his pen in some more worthy and essential form of social medical reform.

I am, Sir, yours truly,

LIONEL A. WEATHERLY, M.D.

Portsmouth, Somerset, July 3rd, 1882.

To the Editor of THE LANCET.

SIR,—Your correspondent "M.D." has hit upon a subject of great interest to the body of general practitioners of this country. But he has not considered the difficulties that surround a general practitioner with a large number of lower middle-class and poor patients, who are able to pay a fee inclusive of charges for medicine, but utterly unable to find money for a fee for the doctor, and also for the cost of the medicine at ordinary prices. For instance, an artisan with an income of thirty shillings per week cannot possibly pay a daily fee of half-a-crown, and a further sum of a shilling or eightpence every two days for medicine. And however much we may appreciate our professional dignity, it is well to have an eye to the practical bearings of the subject. For myself, and I find it the usual custom in this town, I make an arrangement with a druggist to dispense medicine for me at a moderate rate, and I supply my patients and make an inclusive charge. With the better class of patients, who are able to pay both doctor and chemist, I write prescriptions, and they send them where they please.

The system of provident dispensaries, which are a great boon to the working classes, tends to throw the bulk of that class of practice into the hands of a few men who are lucky enough to obtain the appointments. To obviate this, the rest of the junior practitioners are bound, in self-defence, to form medical clubs at about the same rate of pay. Under these circumstances it is impossible to make money at all without some arrangement of charges with a chemist or supplying medicine from a surgery. And as to the question of medical men dispensing their own drug, I have heard from several friends in country districts that they are literally obliged to do so, owing to the absence of druggists, or to the unsatisfactory dispensing of those that exist, and that their patients prefer to have their medicine from the much-abused surgery.

It is surely hardly fair to class all practitioners who dispense their own medicine with the individuals who parade the cheapness of their physic, and who send round circulars calling attention to their giving advice at sixpence, visits at

a shilling, and night visits, according to a recent production here, from two shillings. No expression of public opinion can touch such men, and it is to be hoped that they have their reward, for they eat much dirt in their attempts.

A great objection has been made to the giving of prescriptions to patients, owing to the habit which obtains of their not only dosing the members of their own family with the same medicine under apparently similar illnesses, but of their handing over the prescription to any of their suffering friends. Thus, a medical man may be the means of rendering benefit (?) to a vast number of his fellow creatures with the gain to himself of, perhaps, a five-shilling fee. Now, this is decidedly philanthropic, but hardly lucrative. When we are all physicians or surgeons pure and simple, and all obtain large fees for our advice, then we shall be able to throw up all contact with the base drugs; but until that time many of us who have to attend the poor and needy will have to shape our arrangements accordingly, for surely it is better to allow the poor members of the community to pay a fee in accordance with their circumstances, and thus to feel independent, than to pauperise them or make them recipients of public charity, which is the only alternative.

With regard to the sneer at a certain licence, your correspondent should remember that many English students take a journey to Edinburgh so as to avoid some of the regulations of the body that examines for and grants that same licence.

I am, Sir, yours, &c.,

July 3rd, 1882.

A GENERAL PRACTITIONER.

### URÆMIC CONVULSIONS AND COMA SUCCESSFULLY TREATED BY HYPODERMIC INJECTIONS OF PILOCARPINE, CHLORAL, AND BENZOIC ACID.

To the Editor of THE LANCET.

SIR,—An account of the treatment pursued in the following case may be of interest to certain of your readers, taken in connexion with a similar case described in your issue of June 24th. The patient, a boy of twelve, was suffering from acute nephritis, urine so scanty as almost to approach complete suppression, deeply tinged with blood, and highly albuminous. The treatment adopted at the outset consisted of a brisk purge of compound jalap powder, leeches to the lumbar region, warm blanket bath, and mild diuretic mixture. For two days the case progressed fairly well, but on the early morning of the third day being hastily summoned I found my patient in convulsions, perfectly unconscious, pupils dilated and insensible to light. At this juncture the treatment resorted to was the hypodermic injection of a third of a grain of the nitrate of pilocarpine and an enema of chloral hydrate. Copious perspiration was thus produced; the convulsions continued, however, as frequent but not so severe. On the forenoon of the following day the pilocarpine was repeated, likewise the chloral; similar diaphoretic effects resulting, with decided abatement of the convulsions. With considerable difficulty I now managed to give a dose of jalapine. As soon as the ability to swallow returned, benzoic acid in two-grain doses was administered every hour, and the strength supported by small enemata of beef-tea, to some of which was added a little brandy. From the time the power of swallowing returned benzoic acid was the only remedy used, and its use was continued for six days. It was given as above for the first forty-eight hours of that period and after that in five-grain doses every three hours. During these six days the patient, though free from convulsions and able to swallow, lay in a semi-conscious state, requiring to be spoken to loudly and shaken to get him to take anything. His vision was completely lost. He knew no one, could see nothing held up before him, not even a bright light, pupils still continuing slightly dilated. Under the steady use of the acid the urine increased in quantity, grew lighter in colour, and the albumen lessened daily. His mind became clear and vision once more distinct, convalescence being gradually established. Whether the theory regarding carbonate of ammonia circulating in the blood being the cause of uræmia be correct or not (and the recent experiments of Oppler and Zalesky seem to indicate that it is not), this is the second time within my own limited experience of such cases in which benzoic acid has done good service. Whether its mode of action be the conversion of the

poisonous alkali into a harmless acid and salt, or in what other specific way it acts, I am not prepared to say, but the above is strictly in accordance with facts.

I am, Sir, yours truly,

W. BROWN MOIR, M.D.

Belford Hospital, Fort William, N.B.

## EDINBURGH MORTALITY RETURNS.

To the Editor of THE LANCET.

SIR,—Your intelligent criticism of these returns has already borne fruit. The Registrar-General has acknowledged the inaccuracy of the weekly statement issued from his office, and he explains that, *per incuriam*, the clerk in charge failed to recognise a certified case of diphtheria and one of whooping-cough. The discrepancy in the population return is accounted for by the fact that the annual increase is made by us in the first week of July; and further, that for registration purposes a portion of the extra urban population is included by the Registrar-General in the population of Edinburgh.

I differ from you as to your objection to our custom of eliminating the deaths of strangers in our infirmary, which, from its world-wide reputation, attracts all and sundry, and I submit that, in a small population like ours, it would be misleading to debit Edinburgh with these deaths, which have no connexion with the sanitary state of the town. As to the definition of diseases, which appears to you to be imperfect, it must be remembered that the statement is issued weekly, and that the only abdominal disease of interest to the sanitarian—viz., diarrhoea,—is specially noted.

Your space is too valuable to admit of a discussion of what to officers of health and the public is important—viz., the structure of these weekly reports, and the advisability of similar documents being issued on Monday mornings in all the large centres of population. It is, in my opinion, simply a question of time. I trust to live to see these returns as eagerly scanned by the ratepayers as the price of stocks and the state of the funds.—I am, Sir, yours truly,

HENRY D. LITTLEJOHN, M.D.

Edinburgh, July 11th, 1882.

## PERSONATION AT MEDICAL EXAMINATIONS.

To the Editor of THE LANCET.

SIR,—I am sorry to be obliged to inform you that in a paragraph in your issue of July 8th, you have been misinformed as to the statement of facts. The real condition of affairs is as follows: A person wrote me from Dublin offering me the amounts mentioned if I would personate him at an examination. I thought it my duty to the profession and also to the public to communicate with the Secretary of the General Medical Council at Oxford-street; and, he having referred me to the Branch Council in Ireland, I wrote to them, and the Secretary requested me to continue the correspondence on behalf of the Council there, which led to an exposure of an individual assuming a false name (though I believe a registered medical student) in order to gull me into the belief that he was really the person so registered—e.g., Smyth is very like Smith, and if Smyth were registered as Albert Smyth in the students' register, an Albert Smith might easily pass himself off as the former.

My sole object in exposing this contemptible affair was to save some unfortunate and impecunious brother professional from disgracing himself by receiving a bonus for a contemplated fraud.

I venture to hope this may be a warning to others engaged in like practices.—I am, Sir, your obedient servant,  
York, July 8th, 1882. G. DE COURCY MORRIS, M.D.

## EDINBURGH.

(From our own Correspondent.)

### MORISON LECTURES ON INSANITY.

IN his fifth lecture Dr. Hamilton completed his exposition of the connexions between the several parts of the brain and between these and the spinal cord. He then proceeded to sum up, in the form of an elaborate diagram, the principal points to which he had directed attention. Passing then to

speaking of the functions of the basal ganglia, so far as they are at present known from the results of experiments on the lower animals and pathological lesions in man, he said he could not help thinking that the functional importance of all these ganglia had been very much over-estimated. They were formed in exactly the same way as the convolutions were, simply by thickening of the walls of the various cerebral vesicles. In the lower animals they were very much more highly developed than in man, relatively to the extent of the cortical substance. Destruction of the caudate nucleus produced, so far as was known, very little effect, provided that the inner capsule was uninjured. In one case in which he made a post-mortem examination nearly the whole of the nucleus was destroyed, the inner capsule, however, remaining untouched. The person had no paralysis of motion. The symptoms were of the most obscure nature, and there was nothing in them to indicate that the lesion was situated in that particular part. He thought therefore that the statement which had often been made, that the corpus striatum, or the caudate nucleus, was the centre for motion, was incorrect. With respect to the lenticular nucleus there was a case under the care of the late Professor Sanders in which both lenticular nuclei were destroyed. The person suffered from partial paralysis of the lower extremities, but what was extremely curious was that there was very considerable atrophy of the optic nerve on both sides, and also of the olfactory. The explanation of that was the band connecting the optic nerve with the lenticular nucleus loop. With regard to the optic thalamus, there was a case in which the whole of the ganglion on one side was destroyed except the posterior part. There was no loss of sensation; nothing to indicate that the thalamus was the seat of disease. What, then, Dr. Hamilton asked, could be said of these ganglia? All that could be said was that certain functions, which, apparently, were situated in the basal ganglia, had been transferred to the cerebral cortex by a process of evolution. When it was considered that these ganglia were produced simply by thickening of the brain vesicles, it surely was not a very great stretch of imagination to say that in process of evolution a certain thickening would occur in the cortex, and that gradually functions, which primarily were situated in the basal ganglia, became transferred to that particular part of the brain. It had been found that if the motor centres of the cortex in the dog were excised the animal in the course of time recovered, if not the whole of its motor power, a considerable deal of it. Now, in the dog the basal ganglia were of enormous thickness; and he thought it was by no means unreasonable to suppose that in the lower animals the ganglia had a very much higher function than in man, that they had certain motor functions which in man were transferred to the cortex. He thought everything showed that in man the motor centres had been in great part transferred to the cortex of the cerebrum, whereas in the lower animals the basal ganglia have to be looked upon as discharging, if not the whole, at least a considerable part of that service. The higher we got the more evidence there was that the motor centres, which were seated in the basal ganglia in the lower animals, were transferred to the cortex in man, the monkey, and other animals high in the scale.

The sixth and concluding lecture consisted of a demonstration by means of the limelight of a series of preparations illustrative of the different points which had been described in the previous lectures. It is impossible to speak too highly of the beautiful preparations, and Dr. Hamilton deserves the greatest credit for having introduced a method which promises to clear up many obscure points in the coarse anatomy of the brain. I am glad to hear that Dr. Hamilton intends shortly to publish his method in full, and to lay the results of his researches before the profession in the form of a book.

## GLASGOW.

(From our own Correspondent.)

DR. ANDREW BUCHANAN, late Professor of Physiology in Glasgow University, died on Sunday last, at the advanced age of eighty-four. One of the best known and most highly respected of the members of the medical profession in the city has thus passed away. He graduated in Glasgow University exactly sixty years ago, and thus may be said to belong to that past generation of surgeons

of which we have so few representatives now remaining. During his long career he distinguished himself in many departments of professional work: as a physician in his earlier days, when he fought energetically in the struggle with fever and cholera, at a time when the post of district surgeon in the poorer localities was as full of danger as a prominent post in the field of battle; as a surgeon in the Royal Infirmary here; and finally as teacher of physiology in our University, an office he held for thirty-five years. His name will be associated mainly, however, with the rectangular staff for lithotomy, which he invented and which bears his name. His operation is still frequently practised in Glasgow. On retiring from his professorship he was elected President of the Faculty of Physicians and Surgeons, an honour which he keenly appreciated, coming as it did at a time when his life was clouded, and when he felt despondent at being thrown out of active work. He made a most admirable president, and fulfilled the duties of that high office with a grace and dignity peculiarly his own. The news of his death will be received with extreme regret by hundreds of his former students in all parts of the world.

The scheme for the erection of a hospital in the southern part of Glasgow may be said to be now fairly before the public, and to have a tolerably good basis from which to appeal for support. The Town Council of Glasgow have agreed to let the committee have a piece of ground connected with the Queen's Park, measuring four acres and a quarter in extent, for the purpose of the proposed hospital, the price to be practically a nominal one. Should the hospital not be in process of erection, or otherwise established before Whit Sunday, 1884, the ground is to be reconveyed to the Council.

An outrage, as cowardly as it is fortunately rare, was perpetrated on Dr. Whitelaw, of Kirkintilloch, last Monday night. Shortly after eleven o'clock a woman called at his house and stated that he was wanted at a neighbouring villa, whither he at once set out along with her. When he had gone a short distance he heard footsteps behind; he was then attacked by two men, who knocked him down, garrotted him, and robbed him. One of them kicked him on the ankle, fracturing the bone and causing dislocation. The thieves got but little, as Dr. Whitelaw had left his watch and valuables at home, a small pocket thermometer and a knife forming the chief part of their booty. Dr. Whitelaw was able to crawl back a little way, when he obtained assistance and was carried home. The greatest sympathy is felt for him in the district, where both in public and private life he is known for his kindness and activity in every philanthropic work in the community. No apprehensions have been made, but the police are said to be on the track of the ruffians.

## SCOTTISH NOTES.

(From a Correspondent.)

NEW arrangements with regard to the medical charge of Elmhill Asylum, Aberdeen, have just been completed. Dr. Jamieson, who has acted as superintendent for over forty years, and whose services fully justify the high eulogium of the Lord Provost, will now share the responsibility with Dr. Reid, who has been appointed joint-superintendent. The demand for accommodation in this institution is so great, that at present the propriety of converting the chapel into a female ward is under consideration. The inmates now number 543 in all.

Considerable difference of opinion exists among the profession in Aberdeen regarding the application of £2000 offered to the Directors of the Royal Infirmary by Mrs. Allan's trustees, for the provision of a new consumption hospital. Several members of the staff do not consider the climate of Aberdeen as suitable for the treatment of consumption, and are evidently disposed to utilise the legacy for the purpose of sending sufferers further south, while others are equally convinced of the advantages to be derived from the proposed hospital, and only differ with regard to its site. Probably, an addition to the present infirmary will be made, and the new wing used for chest diseases. In connexion with this scheme Dr. Smith-Shand urges the appointment of an assistant-physician, who would take temporary charge of wards during the absence of any of the

physicians, and possess the same status and privileges as the assistant-surgeon recently appointed.

Two cases brought before the Perthshire Medical Association by Mr. Fergusson, M.B., at the last meeting appear to advance the study of sponge-grafting in wounds, recently proposed by Prof. Hamilton. The first was seen in the practice of Dr. Graham, and brought out some facts not previously noted. The ulcer over the tibia was deep, callous, the size of half-a-crown, with edges hard bound down, and had resisted all treatment for three months. Stimulating lotion made no impression. The unhealthy surface was scratched with a knife until it bled rather freely, when a portion of sponge, prepared according to Hamilton's plan, was applied. In two days this was adherent, but a slight erysipelatous rash had appeared which Dr. Graham feared might be due to the absorption of the decomposing sponge. He removed the sponge, but found that this process caused much pain, and a good deal of bleeding, showing that an intimate connexion with the wound-surface was already established. Repair proceeded quickly, and was complete in three weeks. Mr. Fergusson's case in the infirmary was a most unpromising one. The surface was of varying depth and condition, at one part presenting a deep and slowly separating slough. When this was ultimately removed, a circular, clean-cut, deep depression remained, and this site was chosen for planting the sponge, after the same treatment, both of wound and sponge, as in the last case. On the fourth day a good connexion was established and a healing surface seen. Part of the sponge was removed with the scissors, and on the eighth day the remaining portion was also separated. The same good results noticed in the other case were found here, and the hitherto obstinate ulcer proceeded quickly to repair, especially in the neighbourhood of the sponge. Two minute particles of skin were grafted on that portion of the wound first denuded of sponge, as this was found to heal less quickly, and since then very rapid progress has been effected. Whether it is advisable or not to leave the sponge sufficiently long for incorporation with the tissues may be doubtful, but these cases go to prove that Dr. Hamilton is right in saying that they afford a scaffolding for the uprising tissues.

By the death of Dr. Taylor, Deputy Inspector-General of Fleets, which occurred at Portobello last Saturday, the University of Aberdeen has lost one of its most munificent patrons. Some time ago he purchased the estate of Grena-skare, in Banffshire, at a cost of £10,000, and the proceeds allowed the University to form eight bursaries of £30 each, for the encouragement of secondary education in that his native county. He was eighty-five years of age, and retired about twenty-five years ago.

## PARIS.

(From our Paris Correspondent.)

PROFESSOR GERMAIN SÉE has brought to the notice of the Academy of Medicine a new substance, which promises to be of great therapeutic value. It is an alkaloid extracted from the *Convallaria majalis*, or the lily of the valley. This new alkaloid has been discovered by Dr. Hardy, an eminent chemist, who also discovered the alkaloid from the *jaborandi*, to which he gave the name of "pilocarpine." *Convallarine*, the name of the new substance, has been experimented with by Professor Sée, at the Hôtel Dieu in conjunction with Dr. Hardy, of which hospital the latter is the *chef du laboratoire*. Its therapeutic action is compared with that of digitalis, for which it may be with advantage substituted, as it has none of the inconveniences attributed to digitalis. Dr. Hardy was led to make researches with this plant from the fact of its being generally used by the peasants in Russia, who employ the herb in dropsies, and in all cases requiring increased diuresis. According to Professor Sée, the convallarine is a powerful diuretic, and it has a marked influence on the contraction of the heart, which it regulates, while it lowers the pulse in a remarkable manner.

Oxygenated water, otherwise called the binoxide or the protoxide of hydrogen, which was discovered by M. Thénard, was lately brought to the notice of the Academy of Sciences. M. Paul Bert recommended it some time ago as a powerful antiseptic, and it may be advantageously substituted for car-

bolic acid, which is a powerful caustic, and possesses other toxic properties. Advantage has been taken of this by M. Péan, who has been experimenting with the oxygenated water at the Hôpital Saint Louis with the happiest results. According to M. Péan the water must be absolutely neutral, and it may, according to circumstances, contain from twelve times to twice its bulk of oxygen. This eminent surgeon employed it externally in the dressings of wounds and ulcers of various kinds; he even administered it internally in certain cases of anæmia, septicæmia, diabetes, tuberculosis, and particularly after operations in tuberculous subjects. Even in cases where other means had been unsuccessfully employed, and in which the patients had been threatened with septicæmia, M. Péan obtained the best results in employing it externally and internally. From these experiments M. Péan concludes that as a dressing oxygenated water is far superior to camphorated alcohol and carbolic acid. M. Péan had tried the water in his out-patient practice with the same beneficial results, and it is much preferred by patients themselves to carbolic acid, owing to the objectionable odour of the latter; but the objection to the oxygenated water is its unfixedness, as it decomposes and readily gives off the excess of oxygen, in which case the water becomes like any other common water.

In turning up the earth for laying the foundations for the new General Post Office, which is situated almost at the foot of Montmartre, the workmen came upon some antediluvian remains, consisting of the mammoth or the giant elephant with a mane, to which palæontologists have given the name of "*Elephas primigenius*." It is known that with the hippopotamus and the rhinoceros the giant elephant once inhabited these parts. M. Gaudry submitted to the Academy some fossilised remains of the mammoth, which he found lying deep in these grounds; it was a fragment of the humerus, which gives some idea of the enormous size of this gigantic animal. He also submitted a portion of a tooth which presented some peculiarities of tissue. M. Gaudry also stated that analogous remains were found in other parts of Paris, and on some of the plateaux in the neighbourhood the remains of an elephant approaching more to the modern elephant were also found.

Paris, July 11th, 1882.

## ROYAL COLLEGE OF SURGEONS.

At the quarterly meeting of the Council, held on Thursday last, Mr. Thomas Spencer Wells was elected President of the College, in the vacancy caused by the retirement of Sir Erasmus Wilson; and Mr. John Marshall, F.R.S., and Mr. John Cooper Forster, were elected Vice-Presidents for the ensuing year. Messrs. J. Hutchinson, W. H. Flower, and W. K. Parker were re-elected to their respective professorships, and Mr. H. Power was elected Arris and Gale Lecturer.

The minutes of the previous meeting were confirmed, except that portion of them which related to the one course of lectures on anatomy. The confirmation of this portion was deferred until the reception of a further report from the Nomination Committee, to whom the memorial of the teachers of anatomy against the limitation of the lectures was referred for consideration and report.

A letter was read from the Medical Committee of St. Bartholomew's Hospital, objecting to the institution of a compulsory examination in elementary anatomy and physiology, to be conducted by the teachers at the school at the end of the first year. This letter was referred to the Joint Committee to report thereon when it presents its report on the recent conference of teachers of anatomy and physiology.

Mr. Stone asked, on account of the state of his health, that he might not be nominated for re-election. The matter was referred for consideration to the Presidents and Vice-Presidents.

ON July 5th, the first of the lectures on Natural Science in course of delivery at the College of Practical Engineering, Muswell Hill, was given in the new science theatre at the Alexandra Palace by Mr. Hanks. One of the subjects treated of was the Constitution of Matter, touching which the results of recent investigations were given. The lectures are to be continued daily.

## MEDICAL NOTES IN PARLIAMENT.

In the House of Commons, on Friday, the Lunacy Regulation Bill was brought down from the House of Lords, and read a first time.

### Coffee Mixtures.

Some discussion took place early on Saturday morning upon a Treasury resolution, which was proposed in Committee of Ways and Means, with the view of inserting in the Budget Bill an excise duty on coffee mixtures of twopence per pound, or a penny per half pound packet. The definition contained in the resolution is as follows:—"Any article or substance called by any name of coffee or chicory, or prepared or manufactured for the purpose of being in imitation of, or in any respect to resemble or to serve as a substitute for coffee or chicory, which is sold or kept for sale in the United Kingdom, and also any mixture of such article or substance as aforesaid with coffee or chicory, which is sold or kept for sale in the United Kingdom."—Mr. Courtney, in proposing the resolution, stated that the Treasury had been induced to reconsider their previously intended prohibition of the sale of these mixtures, in consequence of representations of the inconvenience to trade, and of the deprivation which would be caused to persons who had become accustomed to drinking the decoctions in question. Moreover, the makers and vendors were quite willing to pay the proposed duty, which would help to make up to the Revenue for the decline in the receipts from the coffee duty.—Mr. Magniac, on behalf of the London Chamber of Commerce, strongly opposed the resolution, and complained that the Government had brought it on without notice at a very inconvenient hour. He severely criticised their disposition to favour adulteration, and entered into a detailed exposure of the composition of various so-called "coffees" which are now upon the market, which he stated contained only from 6 to 25 per cent. of coffee, added to burnt dates, malt, and other vegetable matter. He sarcastically commented on the undoubted willingness of the vendors of these "horrible compounds" to pay a twopenny duty on an article which cost them twopence, and which the Government recognition implied in the duty would enable them to sell to a credulous public at tenpence or a shilling per pound. In this case, as in the case of patent medicines, the Government stamp would be regarded as a kind of guarantee.—Mr. Gladstone, in reply, said it was the hard fate of the Treasury to be dragged into these questions of adulteration, with which that department had nothing to do. This was merely a preliminary resolution, which, if adopted, would enable the question to be fully discussed on the Budget Bill.—Mr. G. Russell, in an amusing speech, intimated that he held a brief on behalf of his constituents at Aylesbury, who were interested in the manufacture of some of these compounds, particularly "dandelion coffee," which was a substance of a very wholesome and invigorating character. He claimed on behalf of the Aylesbury manufacturers their "time-honoured freedom of adulteration," but intimated that they would be prepared, if required, to abandon the name of coffee in connexion with their products.—Mr. Magniac answered that if that were done his objection would be removed, as the false pretences would cease. As to dandelion coffee, he felt bound to say that it was the only one of these compounds which contained no coffee at all.—Mr. Whitley offered some observations in the interest of malt coffee, and Sir H. Peek and Mr. Warton also took part in the discussion. The resolution was then agreed to.

### Illegal Certificates.

Mr. H. B. Samuelson gave notice of the following question:—To ask the Secretary of State for the Home Department whether his attention has been called to reports in the daily papers of July 6th of an inquest held before Mr. W. J. Payne, on July 5th, in the High-street, Borough, upon the bodies of some children, at which a physician of Guy's Hospital deposed that "it was the common practice to sign 'certificates of death' on the reports of the students, and without seeing the child at all;" and witness further said, in reply to the coroner and jury, that "they were quite aware that by the Act of Parliament they rendered themselves liable to a fine and two years' imprisonment by taking this course. He could see also that for the staff to sign certificates on mere information might sometimes lead to serious results;" and whether, in case of the recurrence of such illegal practices, he will direct the institution of a prosecution of the offenders by the Public Prosecutor.

*Shadwell Fish Market Bill.*

On Monday, Mr. Ritchie, on behalf of the promoters of the Bill for establishing a fish market at Shadwell, stated that the project would be abandoned if the new clauses were allowed to remain which had been inserted by the House of Lords in the interest of the City Corporation. After some debate, the House resolved, without a division, to disagree with the Lords as to the new clauses; and a committee was appointed to draw up reasons to be submitted to their Lordships.

Leave of absence for a week, on account of illness, was granted to Mr. Whalley.

The Lunacy Regulation Amendment Bill, and the Lunacy Districts (Scotland) Bill, were read a second time.

Mr. Shaw-Lefevre stated to Sir R. Cross that the Government intended to introduce a Bill this session to carry out the general recommendations of the Artisans' Dwellings Select Committee.

Mr. Trevelyan, in reply to Mr. Healy, said one of the Irish suspects, named Edward Jennings, had been specially examined at Kilmainham by two eminent medical men, who were of opinion that continued detention would not be dangerous to his health. Further inquiries, however, would be made.

On Tuesday, Mr. Chamberlain replied to Mr. Moore that papers were ready on the subject of the Scandinavian emigrant traffic; but the papers relating to lodging-house accommodation at Hull were not yet completed.

A petition was presented from Mr. A. C. Pipe, for prohibition of the use of arsenic in the manufacture of wall papers.

*Medical Act Amendment Bill.*

Dr. Lyons obtained leave to introduce a Bill to amend the Medical Act, 1858, and the Bill, which bears the names of Dr. Lyons, Mr. Trevelyan, the Attorney General for Ireland, and Mr. Gibson, was subsequently brought in and read a first time.

On the order for the second reading of Colonel Barne's Beer Adulteration Bill, Mr. Courtney objected to the proposal to prohibit the use of sugar, and also to the idea that the Inland Revenue authorities were to be held responsible for the detection of adulteration. The Bill was thrown out by 77 to 47.

On Wednesday, the Royal assent to the Public Health (Fruit-pickers' Lodgings) Act was reported. A petition for exemption of medical men from carriage duty was presented from W. H. Garrington and others.

*Treatment of Irish Prisoners.*

Mr. Sexton gave notice of a series of questions imputing grave misconduct to the Irish police in their treatment of eleven men recently arrested in Galway—viz., that they were marched seven miles through a drenching rain; that they were then kept for hours in a "black hole," which had a "sickening stench"; and that they were refused food or water, although one of them (who had congestion of the lungs) fainted for want of air.

Mr. M. Scott has "blocked" the Committee stage of the Lunacy Regulation Bill.

*Anti-Vaccination Complaints.*

On Thursday, Mr. P. A. Taylor gave notice that he would ask the President of the Local Government Board whether he had received a memorial from the inhabitants of Norwich, giving a list of eight children, four of whom had died, and the rest of whom were at present in a dangerous condition, resulting from vaccination; and whether he would cause a searching public inquiry to be made into all the circumstances of the case.

*Certificates of Death.*

Sir W. Harcourt, replying to Mr. H. B. Samuelson, said that proceedings of a criminal character with regard to signing certificates by medical men "on the reports of students" could not be undertaken without a previous official inquiry. The question, however, ought rather to have been addressed to the President of the Local Government Board.

Mr. Samuelson gave notice that he would repeat the question on Friday.

HICKEY, a caretaker, who was shot in the legs by "Moonlighters" on the 8th ult., died in the Castleisland Infirmary last week, after amputation had been performed.

# Medical News.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**

The following gentlemen passed the Primary Examination in Anatomy and Physiology at meetings of the Board of Examiners on the 7th, 8th, 10th, 11th, and 12th inst.:

J. R. Wilson, E. Bryceson, R. P. Mitchell, T. E. Hornby, and A. W. Popert, London Hospital; G. F. Sydenham, G. C. Henderson, B. J. Innliss, W. M. Gabriel, E. Jessop, F. C. Evill, J. A. Cones, J. J. Hemming, E. E. Gould, and A. G. R. Foulerton, St. Bartholomew's Hospital; H. Vallance, H. M. Addison, W. Lansdale, E. W. Goodall, Charles Fryer, G. C. Stamper, M. W. Oldham, W. F. Tronson, J. D. Howe, J. W. Sindol, and E. S. Marder, Guy's Hospital; G. M. Binett, S. L. Woolner, W. G. Earle, R. F. Bowie, C. D. Hamilton, E. H. Thane, H. C. Smith, C. H. Evans, J. Malpas, H. L. Kempthorne, F. J. Butt, and A. G. M. Creagh, University College; W. G. Weaver and C. R. Davidson, Westminster Hospital; H. J. Roberts, Relfast and Guy's Hospital; J. F. H. Clarke and A. J. Wright, Charing-cross Hospital; A. H. Burns, St. Thomas's Hospital; L. E. S. Beer, Middlesex Hospital; R. Evans, King's College; H. T. Marriott and W. E. Evans, St. George's Hospital; G. A. G. Simpson and Edward Nason, London Hospital; R. Levi, McGill College, Montreal; E. J. Bower, W. M. Hardy, and A. W. Harris, Charing-cross Hospital; Spencer Harbutt, F. L. Mann, and J. B. Drew, St. Mary's Hospital; T. R. Rolston, P. C. G. Billups, Reginald Koettlitz, E. C. Greenwood, and H. G. Hilbers, Guy's Hospital; B. F. Hartzborne, F. G. Armon, and T. H. Maddison, Middlesex Hospital; F. St. John Bullen, Julius Lebay, W. H. Baker, and A. Wilson, St. Thomas's Hospital; F. J. Malden, H. C. Halsted, W. R. Woodall, and S. H. Youel, St. Bartholomew's Hospital; H. A. Seagrove, C. G. Stutchell, George Cornick, C. B. d'E. Chamberlain, A. F. Smith, and H. Marriott, University College.

**APOTHECARIES' HALL.**—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on July 6th:

Adkins, George, South Devon Hospital, Plymouth.  
Graham, George Hubert, Croydon.  
Harris, Frederick William H. Davis, Ivy Bridge, Devon.  
Samut, Richard Philip, Trinity-square, Brough.

The following gentlemen also on the same day passed the Primary Professional Examination:

Percy Alfred Rigby, St. Thomas's Hospital; Daniel Wm. Donovan, Stevens's Hospital, Dublin.

THE foundation stone of a Children's Hospital at Derby was laid this week by Mr. Bass, M.P.

ALEXANDER BECKETT, M.D., of Moneymore, has been placed on the Commission of the Peace for the county of Londonderry.

DR. F. PORTER SMITH, late of Hankow, China, has been elected a Member of the Asiatic Society of Paris, in consideration of his researches in Chinese medical science.

At Oldham two families, including seven persons, are reported to have been poisoned through eating tinned meats. None of the cases are likely to prove fatal. The police authorities have seized the meat affected.

THE Royal Commission on Metropolitan Sewage Discharge met on Tuesday, at 20, Great George-street. Present—Sir John Coode (in the chair), Professor A. W. Williamson, F.R.S., Dr. De Chaumont, F.R.S., Dr. Thomas Stevenson, Mr. James Abernethy, F.R.S.E., and Dr. W. Pole, F.R.S., secretary.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund held on the 11th inst., Sir W. R. E. Smart, K.C.B., M.D., Inspector-General, in the chair, the sum of £70 was distributed among the several applicants.

**BRADFORD MEDICO-CHIRURGICAL SOCIETY.**—The twentieth annual meeting of this Society was held in the board-room of the Infirmary on the evening of June 6th. The annual report expressed satisfaction at the number of members and the work of the Society for the closing session. A report of the Commission upon Woolsorters' Diseases, appointed eighteen months before by the Society, was read and ordered to be printed for private circulation amongst the members previously to its general discussion at a forthcoming meeting. Votes of thanks were accorded to the retiring officers, and the following gentlemen were elected to serve for the succeeding year. President: H. Butterfield. Treasurer: T. C. Denby. Secretary: D. Goyder, M.D. Committee: J. Craig, M.D.; W. H. Ellis; J. Appleyard, M.B.; W. G. Barrie, M.D. Pathologists: T. Wilmot; J. Appleyard, M.B. Auditors: S. C. Hirst; J. Dunlop, M.D.

A NEW Cottage Convalescent Home has been opened at Newhills, N.B.

**ROYAL COLLEGE OF SURGEONS IN IRELAND MEDICAL SCHOOL.**—The following prizes were recently awarded: First Year's Class: First prize (£10), Geo. E. Greene; Second prize (£5), Richard H. Fetherston. Second Year: First prize (£12), Wm. L. Symes. Senior Class: First prize (gold medal and £10), Austin N. Cooper; Second prize (£10), Myer J. Dutch.

**CATHOLIC UNIVERSITY MEDICAL SCHOOL.**—The following prizes have been awarded at the termination of the summer session:—Practical Chemistry: John Buggy, F. W. McCauley. *Materia Medica*: Frederick Mandel. Medical Jurisprudence: Peter O'Connell, Alexander Stewart. Botany: Daniel McDonnell (first); Bernard Forde and John J. Tobin (equal). University Exhibition (£20) in Practical Chemistry, *Materia Medica*, and Medical Jurisprudence combined: Francis W. McCauley.

**NORTHERN COUNTIES ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.**—The annual meeting of the Association was held in the Library of the College of Medicine, Newcastle-upon-Tyne, on the 7th inst., Dr. Clarkson, President elect, in the chair. Among other business transacted, it was resolved that twenty guineas be given to the funds of the Newcastle Infirmary, the donation to be in the name and at the disposal of Mr. Henry E. Armstrong, in recognition of his services as secretary, and with the view of constituting him a life governor of the institution.

**PRESENTATIONS.**—Mr. David Richards, the surgeon to the "Tower" Philanthropic Society, Brighton, has been presented by the members of that institution with an illuminated address, in acknowledgment of his many services in connexion with it as chairman, from which post he had recently retired in consequence of ill-health.—Some of the friends and patients of Dr. R. G. Jack presented him with a farewell address expressive of their regret at his departure from Hampton Court to take up a practice at Kensington. Accompanying the address was a handsome gold watch, with his monogram and presentation inscription engraved on the back.

Two adventurers, named Sutton and Brownrigg, who advertised a work by "Sir John Fleming, M.D.," upon hypophosphites as a cure for all diseases, and who appear to have constituted as their head-quarters a third floor back room in Sidmouth-street, Gray's-inn-road, which they styled "Phosphate Hall," were each sentenced at the Central Criminal Court last week to five years' penal servitude. With the advertisements were issued fictitious notices, purporting to be extracted from THE LANCET and other medical journals, lauding the wares offered to the public by the culprits.

**POOR CONVALESCENTS.**—The annual meeting of the Association for the After-care of Poor and Friendless Female Convalescents on leaving asylums for the insane was held on the 5th inst. at the house of Dr. Ogle, Cavendish-square, when the Earl of Shaftesbury presided. The chief object of this Association is to facilitate the readmission of poor and friendless female convalescents from lunatic asylums into social life—1, by obtaining for them, when needful, a brief interval of change of scene and air, often so beneficial on recovery from ordinary illness; 2, by assisting them to obtain suitable employments.

**CHILDREN'S HOSPITAL, PENDLEBURY.**—The half-yearly meeting of the Board of Governors was held at the hospital on the 8th inst. The medical report stated that during the past six months 478 new patients had been admitted to the hospital, including 70 fever cases, being three in excess of the corresponding period of last year. At the dispensary (Gartside-street) 3621 new cases had been admitted, 708 being home patients. There had been 21,331 attendances in all, including 2143 visits to the homes of the patients. The attendances were 7000, and the new patients admitted 1009, more than during the first half of 1881. This increase had largely taken place in consequence of the continued prevalence of measles and whooping-cough this year. There have been 288 cases of measles, against 22, and 289 of whooping-cough, against 125 during the corresponding period of last year.

## BOOKS ETC. RECEIVED.

BAILLIÈRE, TINDALL, & COX, London.

Manual for the Physiological Laboratory. By V. Harris, M.D. Lond., and D'Arcy Power, M.A. Oxon. Second Edition. pp. 213, with 40 Illustrations.

BLACKIE & SON, London, Glasgow, Edinburgh, & Dublin.

The Imperial Dictionary of the English Language. By John Ogilvie, LL.D. New Edition, edited by C. Annandale, M.A. Vol. III. pp. 793, illustrated.

CHURCHILL, J. & A., London.

The Medical Man's Handy Book. Edited by Wm. Shepperson. pp. 52.

The Student's Guide to Diseases of the Eye. By Edw. Nettleship, F.R.C.S. Second Edition, with Additions. pp. 395, illustrated.

Clinical Lectures on Diseases of the Nervous System. By Thomas Buzzard, M.D. Lond. pp. 406.

FISCHER, G., Jena.

Lehrbuch der Vergleichender Anatomie der Wirbelthiere. Bearbeitet von Dr. Robert Wiedersheim. Erster Theil.

JOHNSTON, W. & A. K., Edinburgh.

The Botanical Atlas. By D. McAlpine, F.R.C.S. Part 8.

KEGAN PAUL, TRENCH, & CO., London.

Catechism of Modern Elementary Chemistry. By E. W. v. Volckxson, F.R.C.S. pp. 286.

Animal Intelligence. By Geo. J. Romanes, M.A., LL.D., F.R.S. pp. 520.

KIMPTON, HENRY, London.

The Etiology, Pathology, and Treatment of Baldness and Grey-ness. By Tom Robinson, M.D. pp. 44.

LEA'S SON & CO.

Transactions of the American Gynecological Society. Vol. VI., for 1881. pp. 542, with Illustrations.

LONGMANS, GREEN, & CO., London.

Experimental Physiology. By Richard Owen, C.B., M.D., F.R.S. pp. 216.

MURRAY, JOHN, London.

Winters Abroad. Intended for the use of Invalids. By R. H. Otter, M.A. pp. 236.

RENSHAW, HENRY, London.

Diseases of the Ear. By Geo. P. Field, M.R.C.S. Third Edition. pp. 335, illustrated with coloured plates and woodcuts.

SMITH, ELDER, & CO., London.

Legal Medicine. By C. Meymott Tidy, M.B., F.R.C.S. Part 1. pp. 636.

A Treatise on Surgery, its Principles and Practice. By T. Holmes, M.A. Cantab. Third Edition. pp. 935, with 418 illustrations.

SPON, E. & F. N., London.

Cyclopedia of Industrial Arts, Manufactures, &c. By C. G. W. Lock, F.L.S. Two vols. pp. 2142, profusely illustrated.

STOCK, ELIOT, London.

Faith the Life-root of Science, Philosophy, Ethics, and Religion. By H. Griffith, F.G.S. pp. 171.

WREDEN, F., Braunschweig.

Die Acuten Infektionskrankheiten. Bearbeitet von Dr. B. Knessner und Dr. R. Pott. Tn. 460.

Lehrbuch der Krankheiten der Peripheren Nerven und dem Sympathicus, f. Aerzte und Studierende. Von Dr. A. Seeligmüller. Tn. 398, mit 56 Abbildungen in Holzschnitt.

Index Medicus, Vol. IV., No. 5. (Leypoldt, New York).—Report of 1088 Cases of Ear Disease, treated in the Glasgow Western Infirmary; by Thos. Barr, M.D.—American Journal of Neurology and Psychiatry, May. (Westermann, New York).—The Physiological and Therapeutical Action of Ergot; by E. Evetzky, M.D.—Rachitis; von Dr. Adolf Baginsky.—Mittheilungen aus der Ophthalmiatrien Klinik am Tübingen; herausgegeben von Dr. A. Nagel.—Sul Valore del Permanganato di Potassa quale antidoto del Veleno del Serpenti (Ofidi); rapporto del Dott. Cav. G. Badaloni.—Della Estrazione della Milza; dal C. Dott. F. Franzolini.—The Uselessness of Vivisection upon Animals as a Method of Scientific Research; by Lawson Tait, F.R.C.S.—Unqualified Medical Practitioners; by D. E. A. Digby.—Quarterly Journal of Microscopical Science, July.—Un Cas de Dermatose Parasitaire observé pour la première fois en France; par le Dr. M. Nielly.—Journal of the Portal Microscopical Society.—Der Uranismus; von W. Bernhardt.—Westminster Review, July.—Dickens's Continental A B C Railway Guide, July.—The Russian Persecution of the Jews; and the approach of the Time of the End; by Wm. O'Neill, M.D.—Facts about Manitoba; reprinted from The Times; with two maps (Chapman and Hall).—Letts's popular Maps of Egypt and Alexandria.—Hare's Life Tables.

## Medical Appointments.

*Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning at the latest.*

- BENTHALL, ALBERT, M.R.C.P. & L.M. Edin., M.R.C.S., M. & L.S.A. Lond., has been appointed Medical Officer and Public Vaccinator to the Twickenham District of the Brentford Union.
- COSHAM, W. RAYMOND, M.D., C.M. Aber., M.R.C.S., has been appointed Medical Officer to the Central District of the Cirencester Union, vice Hodges, resigned.
- DEKLEY, AMBROSE W., L.K.Q.C.P.I., has been appointed Medical Officer to the Sherburn District of the Scarborough Union.
- FENWICK, BEDFORD, M.D., M.R.C.P., has been appointed Assistant Physician to the City of London Hospital for Diseases of the Chest, also a Consulting Physician to the British Orphan Asylum.
- GEM, WILLIAM, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Assistant Medical Officer to the Workhouse Infirmary, City of London Union.
- GILL, JOHN WALLIS, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the First District of the St. Germans Union.
- HEYGATE, FRED. NICHOLAS, M.R.C.S., L.S.A. Lond., has been appointed Medical Officer to the Finedon District of the Wellingborough Union.
- HOLLIS, ELPHINSTONE, M.D., C.M. Edin., has been elected House-Surgeon to the East Suffolk Hospital, in the place of Mr. Wilmot, resigned.
- JONES, W. PRICE, M.D. Lond., F.R.C.S. Eng., has been reappointed Medical Officer of Health for the Kingston-on-Thames Rural Sanitary District.
- LIMONT, WILLIAM, M.B., C.M. Edin., has been appointed Lecturer on Physiology at the Western Medical School, Glasgow.
- MAPOTHER, EDW. DILLON, M.D. Q.U.I., F.R.C.S.I., has been appointed one of the Physicians to the Maison de Santé, Dublin, vice Duncan.
- MCCNICOLL, ROBERT, M.R.C.S., L.S.A. Lond., has been reappointed Medical Officer of Health for the Borough of St. Helen's.
- REDWOOD, THEOPHILUS, Ph.D., F.R.C.S., has been re-appointed Public Analyst for the St. Giles's District.
- REVELL, RICHARD CARTER, M.R.C.S., L.S.A. Lond., has been appointed Medical Officer to the Fourth District of the St. Germans Union.
- RICH, DR. CRESWELL, has been appointed Honorary Medical Officer to the Liverpool Dispensaries, vice Dr. Shearer, resigned.
- SECCOMBE, GEORGE S., L.R.C.P. Lond., M.R.C.S., Senior Assistant Medical Officer, Metropolitan District Asylum, Caterham, has been appointed by the Secretary of State for the Colonies Medical Superintendent of the Colonial Asylum, Port of Spain, Trinidad, West Indies.
- SINCLAIR, J., M.R.C.S., L.S.A. Lond., has been appointed Resident Medical Officer to the Queen Adelaide Dispensary, Bethnal-green, vice Leonard Grant, M.B., resigned.
- VAN BUREN, ERNEST HAWARD, L.R.C.P. Ed., M.R.C.S., has been appointed House Surgeon to the Buckinghamshire General Hospital, vice Valsey, resigned.
- WILLMOTT, JULIUS J. E., M.D., has been appointed Hon. Physician to the Hospital for Sick Children, Melbourne, Victoria, vice Wigge, M.D., resigned.
- YEO, I. BURNIE, M.D., F.R.C.P. Lond., has been appointed Physician to the Life Association of Scotland.

## Births, Marriages, and Deaths.

### BIRTHS.

- DALY.—On the 12th inst., at 185, Amhurst-road, Hackney-downs, the wife of Frederick H. Daly, M.D., of a son.
- DAVIES.—On the 5th inst., at Albert-terrace, Jarrow-on-Tyne, the wife of Hugh Walter Davies, M.R.C.S., L.R.C.P. Ed., of a son, stillborn.
- DAWSON.—On the 8th inst., at Hyde-park-street, the wife of Yelverton Dawson, M.D., of a daughter.
- GRAHAM.—On the 28th ult., at Madeira, the wife of Michael C. Graham, M.D., F.R.C.P., of a son.
- WILLIS.—On the 8th inst., at Gascony House, West End-lane, N.W., the wife of Arthur K. Willis, M.R.C.S., of a daughter.

### MARRIAGES.

- BARR—WOOLLEY.—On the 12th inst., at Holy Trinity, Walton, Breck, Liverpool, by the Reverend Richard Postance, Vicar of St. Titus, Liverpool, assisted by the Rev. F. Grier, Incumbent, James Barr, M.D., of 1, St. Domingo-grove, Liverpool, to Belle, second daughter of the late J. Woolley, Esq., of Springfield, Everton.
- COATS—KNIGHT.—On May 24th, at Ladysmith, Natal, James Coats, M.B., Surgeon, A.M.D., to Augusta Emily, second daughter of the late Humphrey Evans Knight, formerly M.L.C. for Kilp River County, and granddaughter of the late John Baverstock Knight, Esq., of West Lodge, Dorsetshire.
- STAMPER—SMITH.—On the 6th inst., at St. Luke's, Chelsea, J. F. Stamper, M.D., of Pembroke Dock, to Ellen Angela, only daughter of E. A. Smith, Esq., R.N., of Winchester-terrace, Chelsea.

### DEATHS.

- BUDGETT.—On the 19th ult., at Gildridge-road, Eastbourne, John Burgess Season Budgett, M.D., L.R.C.P., aged 72.
- POTTER.—On the 7th inst., at Chipping Ongar, Essex, Frank Dobson Potter, M.R.C.S., L.S.A. Lond., in his 72nd year.
- TAYLOR.—On the 9th inst., at West Brighton-crescent, Portobello, N.B., James Taylor, M.D., Deputy Inspector-General of Hospitals and Fleets.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Notes, Short Comments, and Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*We cannot prescribe, or recommend practitioners.*

*Local papers containing reports or news-paragraphs should be marked.*

*All communications relating to the editorial business of the journal must be addressed "To the Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

### PROPORTION OF MYOPICS IN GERMAN SCHOOLS.

DR. NOBIS, of Chemnitz, has recently published statistical information on the above subject, founded on his experiences at the Chemnitz Gymnasium (or public school). Normal sighted pupils were found in the following proportions:—Sixth grade, 90 per cent.; fifth grade, 83 per cent.; fourth grade, 80 per cent.; lower third grade, 75 per cent.; upper third grade, 65 per cent.; lower second grade, 56 per cent.; upper second grade, 56 per cent.; first grade, 36 per cent. He attributes this result (which embodies a progressive evil) in some degree to the bad paper and small print of the school-books in general use, and in particular to the microscopic characters employed in some Greek works. For this reason he advocates the universal introduction of Roman type, even for the Greek language. The result of his investigations show that on an average 35 per cent. of the pupils at the Chemnitz Gymnasium are short-sighted. The favourable local circumstances of Chemnitz make this average lower than is the case in many German institutions of a similar class, the rate over all Germany being 30 to 55 per cent. The connexion between advancement in study and loss of visual range, which is indicated in the figures we have quoted in reference to the Chemnitz Gymnasium, is (according to the details published) fully confirmed by the returns of German schools in general. In the ordinary Government schools the rate is 20 to 24 per cent., in the higher girls' schools 10 to 24 per cent., and in the elementary schools 5 to 11 per cent., while in the village schools the low rate of 1 per cent. represents the proportion of short-sighted children.

*Omega.*—We regret that the pressure of events led to the communications of "Omega" being mislaid. He should consult his lawyer on the subject.

*E. M. T.*—We have already exposed one of the greatest culprits named in our correspondent's letter, for which we cannot find room.

### "SOUTH AFRICA AS A FIELD FOR MEDICAL PRACTICE."

*To the Editor of THE LANCET.*

SIR,—In some numbers of THE LANCET I have lately received, several letters appear under the above heading. As a general practitioner here of a few years' standing, I think I can pretty nearly state what are the present prospects of a medical man contemplating a trial at the Cape.

In the first place, all the chief towns, such as Cape Town, Port Elizabeth, Graham's Town, and King William's Town, are over-done, and the struggle is quite as severe as at home. At Kimberley or the Diamond Fields there is also a long list of medical practitioners. Now, as to the outlying districts. In the first place, for this work a man must be capable of great physical endurance; able, in case of necessity, to do in the saddle sixty, seventy, or even eighty miles in the day over wagon tracks (not roads). He must be prepared to act in any emergency, entirely upon his own resources, surgical and medical, and in case he fails in one instance, his work is done. He is expected to be a thorough gentleman, but it is advisable that he cast aside all notions of those refined and frequent social gatherings to which men of standing in the profession are generally accustomed in the old country. An individual combining the above requirements, and who, when professional work becomes dull, can turn his attention to shooting (here called hunting) spring-boks and guinea-fowl, may make his 250 a month and his existence endurable.

I should say that of the entire number of medical men who come to this colony, one half return in a very short time to the old country or seek some other field for practice, one half of the remainder go to the bad (drink), and the other half—I.e., one-fourth of the entire number—do fairly well.—I am, Sir, your obedient servant,  
June, 1882.

EIGHT YEARS A COLONIAL.

## USE OF COD-LIVER OIL FOR YOUNG CHILDREN.

*Dr. Frank Nankivell* asks for information as to the age at which a child becomes able to assimilate cod-liver oil, and states that in no case has he known it produce its full effect before the age of eighteen months or two years. We are sure *Dr. F. Nankivell's* results must be exceptional. If diarrhoea or vomiting be present—speaking generally, though by no means absolutely—the use of cod-liver oil internally is contra-indicated in young children, but if neither of these symptoms be present, we cannot recall a more useful agent in the marasmic conditions of infancy. We cannot fix any limit of age, but we have seen infants of a month old distinctly improve whilst taking it, and we should have thought the enormous benefit of this agent to rickety children, both under and over twelve months old, had become a truism in medicine. Even in hereditary syphilis, although it will not take the place of grey powder, in our experience cod-liver oil is a most valuable adjunct in treatment. Also, besides generally helping in the nutrition of a feeble infant, observant mothers often point out that the regular employment of cod-liver oil assists in overcoming the occasional difficulty of constipation.

## AFTER-ATTENDANCE IN MIDWIFERY CASES.

*P. P.*—Certainly not. The ordinary fee is for the usual amount of attendance in an ordinary case. Where puerperal disease arises, requiring special visits or prolonged attendance, it is proper to charge for them specially.

## VIVISECTION.

To the Editor of THE LANCET.

SIR,—It will oblige me if you will give a place to the enclosed correspondence.—I am, Sir, yours very truly, W. C. MACLEAN.  
Army Medical School, Royal Victoria Hospital,  
Netley, July 12th, 1892.

"Society for the Abolition of Vivisection, Henbury,  
"Macclesfield, Cheshire, July 10th, 1892.

"SIR,—The report in the *British Medical Journal* of the 8th inst. leads to the inference that you have not perused the evidence given before the Royal Commission on subjecting live animals to experiments for scientific purposes. The 'crushing exposition' is, we think, on the other side. By this post we forward for your kind acceptance and perusal our controversies with Mr. T. Spencer Wells and Professor Owen.

"I remain, Sir, your obedient servant,

(Signed)

"GEORGE R. JESSE, Hon. Sec.

"To Dr. W. C. Maclean, C.B., Netley,  
Southampton."

"Army Medical School, Royal Victoria Hospital,  
"Netley, July 12th, 1892.

"SIR,—I found your courteous letter here this morning. What appeared in the *British Medical Journal* was nothing but a meagre outline of my discourse to the Southern Branch of the British Medical Association, and gives about as much notion of my argument as a brick would give of the structure of a house.

"I am well posted up in anti-vivisection literature, and I do not think it at all likely you and I are ever likely to agree on which side the 'crushing' has taken place. I dare say Arabi is not convinced that he was 'crushed' yesterday, although perhaps Admiral Seymour may have another opinion on that subject. With regard to Mr. Spencer Wells, I know that the operation he has perfected has saved and is daily saving hundreds of women who, but for him, would have perished miserably. On Saturday last a much valued domestic of my own was operated on by his method, and is now far on her way to a perfect recovery. When Mr. Spencer Wells tells me that the sacrifice of a few of the lower animals assisted him in the work of perfecting an operation that has resulted in such splendid success, you must excuse me for saying that the 'arguments' of anti-vivisectionists, on the other side, count for nothing with me.

"I add that it is nothing less than a scandal that a man who has rendered such noble services to humanity should be assailed as he has been by the Society of which you are the hon. secretary.

"I have only to add, in conclusion, that, so far as I am concerned, this correspondence must end here.—I am, Sir, yours faithfully,

"W. C. MACLEAN, M.D.

"P.S.—You are quite at liberty to publish this correspondence if you please. I hold myself at liberty to do the same.

"To George R. Jesse, Esq."

*Mr. Julius Caesar.*—The subject is noticed in a letter in our present issue.

## INVETERATE BOILS.

To the Editor of THE LANCET.

SIR,—I should feel greatly obliged if any of your correspondents could give me any hint as to the treatment of a case under my care, in which boil after boil appears in different parts of the body. I have tried most of the remedies recommended, but these seem to have no power in averting the above tendency. Glandular swellings also appear in the axillæ and elsewhere, which soon break down into pus, but in a slow, chronic manner.

I remain, Sir, yours obediently,

July 8th, 1892.

SUBSCRIBER.

## EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS.

The following were the questions submitted to the 252 candidates now undergoing their Primary Examinations for the diploma of membership of the College in Anatomy and Physiology:—

## Anatomy.

1. Describe the lachrymal gland, with its position, relations, and coverings.
2. Describe the movements of which the knee-joint is capable, and give the muscles by which these movements are severally effected.
3. Describe the clavicle, and mention the various structures attached to and in relation with it.
4. Describe the œsophagus, its course, relations, and structure.
5. Describe the prostate gland.
6. Give the dissection required to expose the quadratus femoris muscle, and mention the parts in immediate relation with it.

## Physiology.

1. Describe the cycle of the heart's action, stating the relative duration of the different stages, and the events that occur in each stage.
2. State the composition and mode of secretion of the gastric juice. What are its functions? How have these functions been determined?
3. Describe the structure of a large, a medium-sized, and a small artery; and explain the manner in which the circulation of the blood is influenced by the modifications of structure in these different-sized vessels.
4. Describe the structure of nerve-fibres. Of what is their essential part composed? How may the functions of a nerve be determined?
5. Give the structure of unstriated muscular tissue. State the principal situations in which it is found. Compare its mode of contraction with that of striated muscle.
6. Describe the structure of the iris. State in what conditions, and for what purposes the pupil is physiologically contracted.

Candidates were required to answer four, and not more than that number, out of the six questions on each subject.

## INHERITED IMMUNITY FROM ZYMOTIC DISEASE.

To the Editor of THE LANCET.

SIR,—Your annotation of June 24th on Anthrax inoculations leads me to communicate the following stray experiences, which present a certain parallelism with some of those of the French savants, and at the same time are not devoid of obvious practical bearing. My attention was first directed to the subject by my failure to vaccinate successfully an infant whose mother had a mild attack of modified small-pox two months before its birth. When three months old I vaccinated it, arm to arm, three times in successive weeks, without eliciting any sign of invasion. This constitutes my sole experience of infantile insusceptibility, and my stock of lymph at the time was above suspicion. I felt assured of the child's immunity from small-pox, but, as regards the persistence of this immunity, my assurance has been dissipated by my next to be related experience.

Last autumn I attended a fine child of three years through a virulent and, I regret to add, fatal attack of unmodified small-pox, with the leaden-hued, depressed, umbilicated pustules. The mother, whose face presented numerous small pits, explained that, when seven months pregnant, she had a severe attack of small-pox (modified), and that in due course her infant had resisted three successive vaccinations, and been returned as insusceptible. She bore in her arms her next baby, a well-developed child of fourteen months, wanting in vaccine marks. It had been twice ineffectually vaccinated with preserved lymph by the same practitioner, who, concluding doubtless that it, too, had inherited immunity from its mother, thereupon certified insusceptibility. I vaccinated this child on the day of my first visit, after expressing my belief that it must already have contracted its sister's disease. On the eighth day it presented four typical vaccine vesicles, and at the same time a copious variolous eruption of creamy hemispherical pustules, with, on the face, a common florid basis. Recovery was rapid, without a bad symptom. The two cases may be regarded as a crucial test of the antidotal power of vaccinia over variola. The vaccination seemed in no way modified, but presented a curious illustration, no doubt illusory, of the less overcoming the greater.

More recently I attended a patient through a sharp attack of modified small-pox, and six weeks thereafter through her confinement. Four months subsequently I vaccinated her infant, together with four others, from the same arm. All five "took" in every insertion, but, whilst the other four presented large areolæ, in this there was none at all.

I am, Sir, yours truly,

London, July, 1892.

WM. M'LAURIN, M.B., C.M. Glas.

*Krankheit* is referred to a general notice in another column.

*Martin* has not enclosed his card.

*M. G. E.*—The matter is under consideration.

## WHOOPIING-COUGH.

To the Editor of THE LANCET.

SIR,—I write as briefly as possible to recommend the use of sulphate of quinine in large and frequently repeated doses, even for very young children, in uncomplicated whooping-cough.—I am, Sir, yours faithfully,  
July 9th, 1892. M.B.

## RHUS TOXICODENDRON.

DR. G. B. DUNMIRE relates, in the *Philadelphia Medical Times*, a severe case of proctitis and peritonitis by contiguity of tissue by way of the pelvic organs, occasioned by the local contact of the leaves of the *Rhus toxicodendron*.

## THE MEDICAL SERVICE OF BRITISH GUIANA.

To the Editor of THE LANCET.

SIR,—I know something of the medical service of this distant colony and the great good you are likely to do in directing public attention to it. It is one of the many subjects I think which should occupy the attention of the Medical Council, for it is "a public service," employing a large number of medical men. Your able article of the 8th instant points out many of the defects and grievances under which the service labours. The enormous General Hospital of Georgetown affords a most extensive field for practice and study of diseases peculiar to a tropical and most unhealthy region, and its inhabitants, as varied as are the diseases, consisting of negroes, East Indians, the Aboriginal Indian (Malay), Europeans from almost every country of Europe, and Americans of the United States. At my visits to this hospital and the adjacent leper establishments it struck me that the medical and surgical staff was quite inadequate to the wants and requirements of so extensive an institution. The wards of the hospital, especially the surgical division, were very much overcrowded. There is one other point which needs special mention, if only for the protection and encouragement of the qualified medical practitioner. There are men in practice there whose names are not to be found in the Register, and some of them holding public appointments. This point surely is worthy the attention of the Council, as in any scheme for the organisation of a public service the candidates for appointment should be required to possess the qualifications which would enable them to hold public appointments in this country.

I am, Sir, your obedient servant,  
UNITY.

July 11th, 1882.

Mr. S. Coombes.—The statement is scarcely credible.

Mr. Thos. Smith (Darlington).—We regret we cannot assist our correspondent. The name is not in the list in our possession.

## THE AUDITORY METHOD OF DETECTING STONE IN THE BLADDER.

To the Editor of THE LANCET.

SIR,—I have read with much pleasure Mr. Davidson's suggested method of detecting stone in the bladder in to-day's LANCET. I merely write to say that an excellent "lithophone" can be very readily made by attaching one end of an "otoscope" (first removing the vulcanic ear piece) to an ordinary sound, the other end resting on the ear of the surgeon. The otoscope is in such constant use, both for purposes of diagnosis and treatment, with aural surgeons, that the wonder is the method recommended has not suggested itself sooner. Having made experiments, I can corroborate Mr. Davidson's statements as to the utility of the "lithophone," and beg to congratulate him on his discovery.—I am, Sir, your obedient servant,

WM. CAIRNS WICKS, M.B., M.C., &c.

Newcastle-on-Tyne, July 1st, 1882.

To the Editor of THE LANCET.

SIR,—If your correspondent will be good enough to refer to THE LANCET of October 14th, 1876, he will find the same instrument fully described by Dr. Leftwich, for whom we originally made them.

We are, Sir, your obedient servants,

London, July 11th, 1882.

ARNOLD & SON.

## LORD DALHOUSIE AND LORD CHELMSFORD ON THE DESIGNATION "NON-COMBATANT."

To the Editor of THE LANCET.

SIR,—I beg you will give a place in your journal to the following extracts:—

1st. Lord Dalhousie's minute on the Indian Medical Service, 1856.—"The medical officer in respect of real rank, dress, honours, and promotion should be placed on a footing with his brother officers. The absurdity of regarding the medical officer as a non-combatant is, I believe, abandoned."

2nd. Lord Chelmsford's speech at the Grocers' Company in 1879, on his return from South Africa.—"I trust that the designation by which it is usual to stigmatise (for I can call it by no other name) those who belong to the several army departments—viz., non-combatants—may now be changed. Everyone must know how dependent an army in the field is upon the efficiency of its commissariat and transport, its medical and pay arrangements, and it seems to me most unfair, because, as a general rule, on active service duty does not call to the immediate front those who belong to those departments, that a name should be given to them which seems to imply an inferiority of position to the other branches of the service. The late war in Zululand has shown, what must have been known before, that when occasion requires it departmental officers can exhibit the highest personal courage, and can win for themselves that proud distinction which is principally gained by the so-called combatant officers."

I would ask, how long are these objectionable terms to be used?

I am, Sir, yours, &c.,  
N. A. T.

July 11th, 1882.

## A MISSING LINK.

A UNIQUE fossil found amongst the mammalian remains in the phosphorite deposits of Quercy has been brought before the Académie des Sciences by M. Filhol. The fossil is one in which the characters of the pig and the monkey are united, and is the first perfect one of the kind on record, though part of an upper jaw very like it was found some years ago in the upper eocene strata near Apt. It is surmised that during the late eocene period a class of animals existed which might be described as "Pachysimlae."

## VACCINATION: P. A. TAYLOR v. DR. CARPENTER.

To the Editor of THE LANCET.

SIR,—I have read the articles by Dr. Carpenter and Mr. Taylor in the *Nineteenth Century*. Neither time nor space will allow me to say what I should like to on the subject, yet I should be glad if you could allow me to make a few remarks very briefly.

First, the saying as to the fallacy of statistics seems exemplified here, for both bring forward figures so fully that I am confused, and I must leave others to prove them. I prefer being guided by my experience as a public vaccinator lasting over thirty-four years. Page 785, Mr. Taylor says, "any taint in the blood of a person from whom the lymph is taken is communicable to the person into whose system the diseased matter is conveyed." My experience gives no proof of this, and if blood is not taken I think it is impossible. Mr. Taylor insinuates that the medical profession advocate vaccination from selfish motives. This is unjust, for if vaccination were not followed I should get hundreds a year, whereas I now only get twenty pounds from public vaccination. A severe case of small-pox may last for weeks, and leave blindness and other ailments requiring treatment for years.

Page 790, Mr. Taylor confuses vaccination and proper vaccination. If the patient is "without the faintest mark" I should consider him unvaccinated or unprotected for all practical purposes. That proper vaccination will prevent and mitigate small-pox I am, from my own experience, as much convinced as I am of any fact—say of the circulation of my blood. I have seen in a family of ten the only unvaccinated person take confluent small-pox, and I have also seen in a family of six only one escape, the one who alone had been vaccinated; three of the five unvaccinated died.

I wonder that there should be any dispute about a fact which can be demonstrated. Let Mr. Taylor try this experiment:—Bring three children into a room with small-pox; let one be properly vaccinated first, the other two not at all. In twelve days or so the two unvaccinated will show symptoms of small-pox; then let one of them be vaccinated properly. From my own experience I can confidently predict this result. The vaccinated child will escape; the other two will take small-pox; they will seem to have it equally badly, but after the eighth day the child vaccinated (when the seeds of small-pox were in him) will suddenly recover and ask for food; the unprotected child will then begin to be in greater danger.

A tramp brought a child to my surgery lately. The rash was in the first day's stage. It had never been vaccinated, so I did it at once. The child was dangerously ill afterwards, and we all expected it to die. The vaccination seemed to outrun the small-pox, and the child suddenly began to improve after the eighth day. I could quote many such cases. There is a popular fallacy I should like to mention; it is that unsanitary conditions would create small-pox. Without the seeds of a previous case you could no more get a case of small-pox than you could get an oak without an acorn. Take the small-pox seeds to the palace or the cabin, and it will equally spread to all who have not already had small-pox or who have not had the modified form of it, called vaccination. Many expect too much from vaccination. It only gives the same immunity from small-pox that small-pox does to a second attack; no more, no less.

I am, Sir, yours truly,

Herts, June 30th, 1882.

ALFRED THOMAS BRETT, M.D.,  
Public Vaccinator.

A. J. S.—The fittings of a water-closet should never alone be trusted to keep sewer air out of a house. This should be effected by means of two openings in the house drain, so as to secure a through current of fresh air, supplemented by a trap between the house-drain and the sewer. A valve-closet with a syphon trap is the best to procure. Above all, closets fitted with either a "container" or a "D trap" should be avoided.

R. M.—We are not aware.

A Resident and A Sanitary F.R.C.S. will oblige by forwarding name and address in confidence.

A Reader of The Lancet.—Our advertising columns frequently contain the information desired.

## READY TEST FOR SEWAGE IMPURITY IN WATER.

To the Editor of THE LANCET.

SIR,—Permit me to say that Messrs. Negretti and Zambra have carried out the suggestion which I threw out in a letter to THE LANCET last year, and have made hermetically sealed glass capsules enclosing the test. A box of these, with directions for use, will be found serviceable for travellers in enabling them to detect sewage impurity in drinking water.

I am, Sir, yours truly,

Lynn, July 8th, 1882.

## Clinical Lecture

ON

## THREE CASES OF SEVERE INJURY TO THE HEAD.

By ROBT. JOHN GARDEN, M.D., C.M.,

LECTURER ON CLINICAL SURGERY AT THE ABERDEEN  
ROYAL INFIRMARY, SURGEON TO THE HOSPITAL  
FOR SICK CHILDREN, ETC.

GENTLEMEN,—The first case I bring under your notice to-day is the man I now show you, who has been under observation for some time in the wards. His history is as follows. He was admitted on October 16th—that is, fully three weeks ago. The account given of him was that when drunk he fell down a stone staircase, lighting on the back of his head with considerable force. He was brought to the hospital, and his condition was found to be this. On the back of the head there was a contused wound of the scalp running crossways and about one and a half to two inches in length. The bleeding was considerable. The wound extended in depth to the bone, the pericranium being laid bare. On examining with the finger there was no slit or depression in the bone. Blood was issuing in moderate quantity from the nose and left ear. Generally, the patient was insensible and lay on his back with the muscles of the extremities relaxed. The face was pale, the skin generally blanched, with the surfaces cold (temperature lowered). The pupils were regular, rather dilated, acting slowly to light. The breathing was shallow and quiet, with occasional sighing. The pulse was 60, small, empty, and uneven. The treatment adopted was simply application of warmth to the surface of the body, and attention to the wound, which was washed with a solution of carbolic acid and dressed with antiseptic dressings.

October 17th: Pallor on left face and skin; patient beginning to be restless; insensibility not so deep; can be more easily roused; is irritable when disturbed, especially if his eyes, which are kept firmly closed, be opened; speaks incoherent when roused. Retention of urine, catheter had to be used. Pulse 100, fuller, quicker, and more even; temperature 101°. Wound doing well.—18th: Patient still restless and irritable; lies on his side with legs and arms flexed; face flushed and head hot. Pulse 102; temperature 102°. Cold applied to head. Wound doing well.—19th: Patient still restless, irritable, confused, and incoherent. Pulse 108; temperature rose in the evening to 103.5°. Patient had an enema of house medicine and soap. Use of catheter no longer necessary. The high temperature continued for several days, and gradually subsided; the patient gradually regained consciousness and became rational. Pain in the head was complained of and deafness. He is now as you see him, almost well. He complains occasionally of pain in the head, and feels dizzy when he stands up. His memory is somewhat defective, and his manner generally is peculiar. Temperature and pulse are normal. On the left ear he is very deaf. On examination with the speculum, there is a raw line extending across the membrana tympani, pointing to a rent having been present.

The second case I shall relate is a most interesting one. About two years ago I was called to see a youth, aged seventeen, who had sustained a severe injury to the head. The history I got was that the lad was standing with his hands in his pockets near some companions who were throwing the hammer. His back happened to be to the thrower. The hammer swerved from a straight course, and made directly for the boy's head. He was called to, ducked his head, but only so far as to bring it exactly athwart the parabolic course of the weapon, which felled him bleeding to the ground. When I saw him he was lying on the floor of a house into which he had been carried. On the upper and back part of the head to the left side there was a wound surrounded by a considerable swelling of a soft, doughy nature with hard edges. Generally, he was insensible, or could be roused slightly when spoken to very loudly; the face was pale, and the surface of the body cold; the

breathing was shallow, quick, and tolerably regular with occasional sighing; the pupils were unaffected, sensitive, though somewhat slowly, to light. On consultation with Dr. Rodger it was resolved to enlarge the existing wound, and evacuate the blood effused into or below the scalp. This was done in order to examine the state of the bone. On doing so, and getting rid of a large quantity of effused blood, there was found a large, deep, circular depression of the skull, with a diameter of at least three inches, and corresponding to the globular hammer which struck it. The outer table of the skull was shattered, several large fragments were removed, and these I now show you. The inner table was depressed but regular—that is to say, there appeared to be no spicula projecting into the brain likely to give rise to irritation. As the symptoms were solely those of concussion, and no signs whatever of compression manifested themselves, the edges of the wound were brought together, except at the centre, where a sufficient opening for the escape of any discharge was left. Cold water dressings were applied. Some time after this the patient vomited. Now, gentlemen, it would but weary you to detail the course of this case. Suffice it to say that it ran uninterruptedly towards recovery. Under the influence of warmth to the surface of the body the symptoms of collapse gradually wore off. The mental symptoms disappeared, and consciousness was slowly recovered. There was no great reaction. The temperature at no time rose much above 100°. From first to last there was no unequivocal sign of compression. The wound healed slowly by granulation. The youth is now in perfect health, bodily and mental—bereft, it is true, of a large piece of the outer table of his skull, and having a permanent depression of great depth and size of the inner table.

The third case is that of a dyer, aged fifty-three, who was admitted into Jacob's Ward on the forenoon of Saturday the 22nd of May last. The account was that when drunk he had, that forenoon about 10 o'clock, fallen down a stone staircase and alighted on the top of his head. At the visit at 12 o'clock his condition was as follows. He was lying on his back, insensible but not profoundly so, for he could be roused when spoken to loudly, but only roused. His face was pale, surface of body cold. The pulse was about 80, small and empty. The breathing, though slow, was shallow. The pupils were slightly contracted but regular. On the top of the head, on the right parietal and frontal bones, there was a slight swelling, but no wound or depression. That was at 12 o'clock. In about an hour and a quarter—that is, about three hours and a quarter after the receipt of the injury, matters had very much changed. The insensibility had increased and developed into profound coma. The pupils were now irregular, the left was much dilated and right still contracted. The breathing was slow, deep, stertorous, with puffing of the cheeks. The pulse was fuller and slower. The left arm and leg were rigid as compared with the right. The urine was retained and contained albumen. The swelling on the top of the head was much more distinct. Rapid intracranial effusion of blood was diagnosed. A consultation was held to consider the propriety of an operation. It was concluded not to operate on the grounds that the patient appeared to be moribund, and it was impossible to say in what part of the brain the bleeding was taking place, whether on the surface or at the base. This decision I afterwards had reason to regret. Meanwhile the symptoms progressed. The rigid muscles of the left side became paralysed. The face became flushed, and perspiration poured from it. The pulse was now full and very slow, but immediately before death small and quick. The temperature rose, and immediately before death was 104°. The patient died thirty-eight hours after the receipt of the injury. At the post-mortem examination there was extravasation of blood in the scalp over the right frontal and parietal bones. There was simple fissure of the skull, at the anterior part being separation of the inter-parietal suture, and, as it extended backwards, diverging into the right parietal bone. There was no depression. The upper surface of the brain was lacerated, and a large quantity of blood effused below the dura mater. The kidneys were granular.

Injuries to the head have always had and always will have a peculiar interest to the surgeon. In the literature of surgery affections of the head and brain occupy a very prominent place. Since the classical writings of Pott and Abernethy much has been written on these, as they have received the most careful attention from all surgeons of

C

note. For this there are many obvious reasons. Extremely liable to injuries of various degrees of severity, from slight cut or bruise of the scalp to severe compound fracture of the skull and laceration of the brain, it falls to the lot of every surgeon, nay, every practitioner, to treat many of these, and on the judicious or other management of even the apparently most trivial cut may depend to the patient consequences of the gravest kind. In these the possible dangers immediate or remote are very many, and in these more than in any other affections that I know of is the unexpected wont to take place. A patient comes to you with a slight cut on the head the result of a fall or blow. You, thinking the matter trivial, assure your patient that the injury is of no moment, and dismiss him after a two minutes' consultation, occupied mainly with general remarks. You hear nothing of him for a day or two, when you are sent for to see him and find him in bed. A rigor and it may be sickness have seized him. The wound looks angry, a suspicious redness surrounds its edges. Great general depression characterises your patient, and despite all your precautions your patient, especially if he be an elderly and debilitated individual, is dead within a week of receiving his injury from erysipelas of the most malignant type. On the other hand, you are called to a case where very severe injury has been received. You find severe contusion to the scalp and soft parts, unmistakable fracture of some part of the skull, and with it very great depression, while the general appearance of the patient is alarming in the extreme. You rapidly form and express a prognosis of the worst kind. Notwithstanding this the patient may take a turn, reaction set in, and complete recovery take place. Now these are no fancy pictures, they occur in practice every day, and the fact that they do teaches these two lessons. In the first place think not too lightly of any injury to the head, however slight it may at first sight appear; warn your patient of the possibility of serious mischief accruing if the wound be neglected, and if serious consequences follow—as they may do in any case—then you are commended for your foresight. On the other hand, however desperate the case may appear, do not too rashly volunteer a bad or fatal prognosis, as you may find yourself very unexpectedly in the wrong. Hippocrates it is, think, who, with his usual sagacity, has a remark to this effect, that no wound of the head is too trivial to be neglected, and no injury too severe to be beyond hope; and Hippocrates undoubtedly is right.

Now, with these general remarks, let us look a little more closely at the cases I have brought under your notice. These are very fair examples of the conditions known as "cerebral irritation," "concussion," or commotion of French writers, and "compression." Now, the first remark I would make is that one of the difficulties we, as clinical teachers, have to contend with is that students straight from systematic lectures, or from reading books, are apt to expect to find cases much more typical, so to speak, than they usually are. For example, take "concussion" and "cerebral irritation," two conditions, each presenting a certain series of symptoms, with which you are familiar in your systematic lectures. Now, you find, and this is only a necessary condition of the systematic exposition of a subject such as the one under consideration, certain symptoms given as characterising the one, and certain symptoms as belonging to the other of these states. From this you would expect to find in actual practice each example of the one condition or of the other sharply defined, so that you would be enabled to say categorically this is "cerebral irritation," or this is "concussion," as the case may be. This is far from what you will really experience. The science of clinical surgery is of the most concrete kind, each case forming a problem to be solved in itself, generalisations being only to a certain extent applicable.

Of the cases I have cited two recovered and one proved fatal. Look particularly at the symptoms of the early stage, and you will be struck with the similarity of these in all three cases. In all there had been a severe blow to the head. In all three there was immediate insensibility; in all three there were paleness of face and pallor of body; in all three there was shallow breathing; in all three there was small, rather slow, empty pulse; in all three the pupils were neither dilated nor contracted, but regular and acting slowly to light. These lasted for a longer or shorter time in all three. Now, what do these symptoms point to? Well, they are just the symptoms of "concussion"—that is to say, they are the symptoms which you find after a severe blow to the head, when either recovery may take place, or death may quickly

follow, and the post-mortem examination may show neither depression of the skull, nor laceration of the brain, nor effusion of blood. In other words, there was in all three, disregarding meanwhile the termination of the cases, a first stage of "concussion." This is what, I believe, happens in the great majority, if not in all, cases of severe injury to the head; indeed it is difficult to conceive of the possibility of force sufficient to cause fracture or laceration of the brain and hæmorrhage being applied to the skull without causing this "concussion," especially when it is remembered that a mere blow from the fist often suffices to cause stunning, which is no other than slight concussion with temporary effects. From this statement it follows that it is, strictly speaking, incorrect to compare or contrast "concussion" with "cerebral irritation" and "compression;" for, as we shall afterwards see, these belong to different stages altogether of the effects of a blow.

Now, what is this "concussion"? What is this obscure, mysterious condition which is accompanied by symptoms so severe, and which may be so transient? Much has been written on this subject, and the older writers were greatly in the dark about it. They were therefore left to assumptions which recent investigations have clearly proved to be untenable. Before referring to the explanations which have been offered, I should like to point out that the one outstanding symptom common to these cases is insensibility of greater or less profundity and of longer or shorter duration. This points to a suspension of the functions of the cerebrum, and the question is, "How does a blow, how can a blow effect this?" The answer to this resolves itself into an account of what pathology and physiology have taught us on the matter. It must be remarked that the pathological changes in the brain are often remarkably slight to appearance and may be overlooked. This it was that misled Pott and writers of his time, and drove them to the first assumption in regard to the condition of the brain—viz., that as a result of the blow vibrations occurred; these reverberated from the side of the skull opposite to that receiving the blow; and thus, by a series of reverberating vibrations, there was caused molecular displacement of the minute elements of the brain. Now, gentlemen, consider for one moment, and do you think it at all probable, having regard to the extremely fine constitution of the brain, that all this shaking can take place without producing laceration and consequent hæmorrhage? But apart from this, is there reason to believe that a blow, however severe, can, in the conditions in which the brain is placed—viz., in a cavity with unyielding walls, and completely filling that cavity—I say is there reason to believe that a blow can produce such a thorough and through shaking and misplacement of molecules as this theory supposes? Experiments of a very interesting kind come to help us here, and, to my mind, settle the question in the negative. Alquié and Gama took a glass vessel, filled it with material of the consistence of brain, suspended in it a number of fine dark threads, and then concussed the vessel. No motion of the threads whatever was observed, showing that, although there may have been motion of the whole mass, the individual particles did not move. Similarly skulls filled with sand, in which an opening covered with a membrane had been made, and into which a long needle with paper on the end had been sunk, gave entirely negative results. There is, in fact, no evidence that such molecular changes as supposed by Pott to take place occur, and his theory consequently falls to the ground.

Another theory is that based on the discovery of Rokitsanski and Nélaton—viz., a number of minute extravasations of blood in the brain. The theory was that the pathology of concussion was just a contusion of the brain with small extravasations. Unfortunately for this theory, it is an undoubted fact that cases occur where these apoplexies are entirely absent; and all, therefore, that can be inferred from their presence is that concussion and contusion occasionally co-exist.

I come now to the third and by far the most feasible theory of concussion—viz., that propounded by Fischer of Breslau.<sup>1</sup> It is shortly stated thus: The blow to the head produces reflex paralysis of the vessels of the brain. Serious interference with the nutrition of the cerebral ganglia is produced, and this it is which gives rise to the symptoms of concussion. In this connexion it is necessary to state that the one constant condition found post-mortem in fatal cases

<sup>1</sup> For a full discussion of this theory see a very interesting clinical lecture, entitled *Ueber die Commotio Cerebri*, by Fischer, forming No. 27 of Volkmann's *Sammlung Klinischer Vorträge*. 1871.

of concussion is an empty state of the arteries and a congested state of the veins. This is the pathology of concussion. Looking at the question from a clinical point of view, and without going minutely into the matter, which would be impossible now, it will suffice to ask, and if possible answer, two questions—viz., 1. Can a blow applied to the head produce this paralysed state of the vessels? 2. Given this condition of the vessels, does it account for the pathological appearances found after death and the symptoms during life? In regard to the first question, there is evidence that a blow can produce such a condition. It is well known that irritation applied to the skin may produce a marked reflex effect on the vessels of the brain and elsewhere. Nothnagel irritated by electricity the skin in the neighbourhood of the crural nerve in rabbits, and thus produced reflex contraction of the vessels of the pia mater. This contraction, however, was always of very short duration, and, as Fischer points out, does not explain the duration of the symptoms of concussion. Other experiments, however, are more to the point. Goltz has shown, in his well-known experiment of giving a blow to the belly of a frog, that paralysis of the heart and vessels can be produced, and that symptoms very similar to those of concussion accompany it, while Koch and Filehne, by concussing the skulls of dogs and rabbits by a series of rapid blows with a hammer, produced the same results. These experiments certainly go very far to answer in the affirmative the first question. In regard to the second question it is sufficient to say that an empty state of the arteries and a congested state of the veins is the only condition which is found constantly to accompany the symptoms which clinical observation discovers to be those of concussion, and that this condition is that which results from paralysis of the vessels and, it may be, a partly paralysed state of the heart. So much for what I have called the first stage of all the three cases, and its explanation. In all three the symptoms were identical; the cases differed only in the duration of this stage.

On following the cases further, they are now found to diverge. What is called reaction sets in. The paralysed condition of the vessels and heart begins to wear off. The tide of stronger circulation sets in. In the first case the symptoms I have described manifested themselves. They were—(1) Patient extremely irritable; (2) patient lying on side, with legs drawn up; (3) eyelids firmly closed; (4) quick pulse and fever, temperature reaching 103°; (5) mental symptoms lasting two or three weeks. Now, what do these symptoms indicate? They are fairly marked symptoms of a condition which has been called "cerebral irritation," and what is that? I believe it to be no other than a variety of the stage of reaction, or more properly perhaps a degree of reaction. It is probably due to a hyperæmic state of the brain, more particularly of the meninges, as evidenced by considerable rise of temperature and febrile symptoms generally. The symptoms of this condition have always appeared to me to be very similar to those found in non-traumatic cases where inflammation of the membranes of the brain is believed to exist. But what of laceration of the surface of the brain? Is that not the pathology of cerebral irritation? There is no positive evidence to show that it is. Experiments on animals prove that the cerebrum can be cut or torn to a considerable extent without giving rise to marked symptoms. Clinical experience points to the same conclusion. In a remarkable case which happened in this hospital, under the charge of the late Dr. Kerr, where a man bending forward in front of a circular saw in motion had his forehead ripped open, and the brain so lacerated or torn that a considerable quantity of brain substance escaped, recovery took place without any marked cerebral symptom whatever. It is extremely doubtful if laceration *per se*, and apart from hæmorrhage and secondary changes, does give rise to any symptoms other than those that would result from destruction of the part of the brain lacerated. It is certainly not rational to ascribe the symptoms of cerebral irritation to superficial laceration. Be the exact pathology of cerebral irritation what it may—and our knowledge of matters cerebral is anything but complete—what I wish to point out is that, looked at clinically, it belongs to the second reactive stage of concussion, and it is therefore unscientific, as inconsistent with observation and fact, to contrast it with this as if it were a distinct condition *ab initio*. One other symptom in this case calls for remark—viz., bleeding from the ear. What did that indicate? In this case probably only rupture of the membrana

tympani. There was no escape of clear fluid, and therefore nothing to point to fracture of the base of the skull.

The second case was a more typical one of concussion, where the symptoms gradually subsided, the general paleness disappeared, the pulse recovered, and consciousness gradually returned. Vomiting took place as reaction began. The reactive febrile symptoms were moderate. Perfect recovery took place. The interest attaching to this case was the depression of the skull. In this case there was about as much depression as well could be, and yet from first to last there was not a single symptom of compression. Now, this raises the important question, Can depression of a fragment of bone, acting as it does on only a comparatively small part of the brain, and apart from any secondary changes which may make place as the result of the blow and depression, give rise to symptoms of compression? If this case teaches anything at all it indicates that it is exceedingly doubtful if it can. Now, gentlemen, I do not wish to speak dogmatically or infer too much from one case, but a case such as this, admitting the possibility of such a thing, forms a very staggering exception, and, I think, has great value attaching to it when weighing facts and evidence *à propos* of this question. When it is remembered that previously symptoms were ascribed to compression which belong to concussion simply because depression was present, and when the fact is taken into account that experiments on animals performed by Pagenstecher and others (which I need not detail) show that distinct symptoms of compression come on only after a large quantity of fluid is forced into the skull and produces great pressure on the brain, then it is extremely difficult to see how a depressed piece of bone, exerting at most a comparatively slight degree of pressure and acting only on a very limited part of the brain, can determine symptoms so marked as those of real compression.

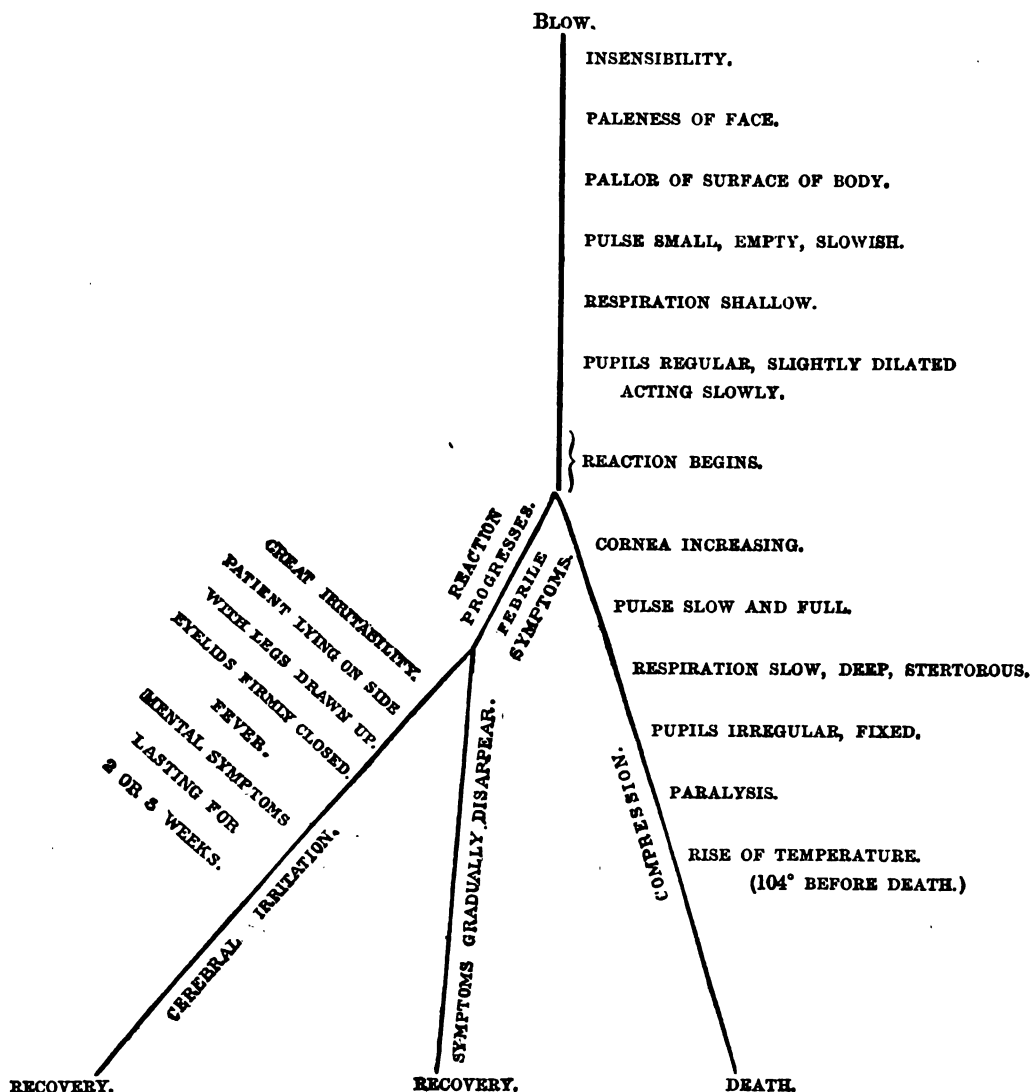

If, then, depression of bone does not produce symptoms of compression, what does? Our third case, I think, goes far to answer this question. Here we had a first stage of concussion, and here, too, reaction set in, but with a very different result. There being considerable laceration of the brain and rupture of vessels, with the recovering circulation hæmorrhage took place. There was found post mortem a very large effusion of blood. Now, apart from an effusion or abscess formation that may occur later in the history of any given case of injury to the brain, it is highly probable that this is the constant cause of real compression occurring early. What, then, are the symptoms of these conditions? Our case gives us them. They are:—(1) Coma increasing in profundity; (2) pulse becoming slow and full; (3) respiration becoming slow and stertorous; (4) pupils uneven; (5) paralysis; (6) temperature rising as symptoms increase. These are unmistakable symptoms, and they come on after symptoms of concussion; and, like cerebral irritation, compression is an outcome of concussion. Instead, then, of putting the symptoms of these conditions, as is usually done, in parallel columns, I have arranged the symptoms in diagrammatic form (see next page), showing at a glance the course any given case of injury to the head may take. Of course this table has not reference to any secondary complication that may arise, such as abscess formation, and it should be remembered that all the stages vary much in duration in any given case. If death take place from concussion *simpliciter*, as it may do, then it is likely to occur very early. So much for the symptoms. As to *diagnosis*, our cases did not present any great difficulty. In the third case, at one stage the question "Drunk or dying?" might have occurred; but the very rapid course of the symptoms very soon made the real state of matters clear.

Now, gentlemen, what do these cases teach us as to the treatment of severe injury to the skull? In other words, suppose you were called to see a case similar to any of these I have described; what would you do? and why? In the first stage the indications would be to restore the enfeebled circulation. This is effected by applying warmth to the surface of the body by means of hot bottles, &c. If the collapse be profound friction to the surface of the body, or the application of an irritant, such as mustard, will do good. It is no use being too officious at this stage, as time must be allowed. During the reactive stage, if there be symptoms such as those we have in the first case—viz., those of so-called cerebral irritation, then cold to the head, shaving the hair, darkening the room to obviate the irritating effects of light, will be beneficial. If there be insomnia bromide of potassium, alone or combined with chloral, will be found useful. In all cases attend to the bladder and bowels,

keeping the latter tolerably freely open. In cases such as the second the indications for treatment are few beyond attention to the bowels. But this case and the third case suggest very interesting questions as to local treatment, and more particularly as to when and what operative procedure should be employed. What are the conditions that render early trephining necessary? This is the great question that has divided surgeons. Pott laid down the law very strongly that this operation should be done in all cases of fracture of the skull with depression, and, after describing the operation and various measures to be employed, he complacently

fracture with depression is not an indication for operating. This is just exactly what would be expected from what I have already said when discussing the symptoms as to depression being a cause *per se* of compression. Depression of a part of the skull, it was argued, cannot give rise to symptoms of compression. Elevation, therefore, is no use. But what of our third case? In this case there were indications for trephining; and I regretted that the operation was not done, although the reasons for not doing it were quite valid. There were distinct indications of compression, although without depression, and it would have been interesting to have

indicates that the surgeon who has adopted these may say to himself, in the words of Pope,—

"Thus far was right; the rest we leave to heaven."

Heaven, however, was not in many cases too propitious. This dictum of Pott's was followed by surgeons at the time blindly. Thus it has been too often in the history of surgery. Many a *hereditas damnosa* has been handed down in this way. Abernethy, however, put a check on it; and from the observation of cases where he found that fracture with depression did not of itself in every case, or in the majority of cases, prove fatal, advised waiting for symptoms. He simply used his own judgment, and he was right. What do our cases teach as to this point? If there be anything that our second case proves at all, it is this, that fracture of the skull with marked depression is not an indication for trephining. But it teaches more: it shows that compound

seen if these would have been relieved by opening the skull. Here, again, we have corroborated what we have previously said as to the cause of symptoms of depression coming on early—viz., that they are probably due in all cases to rapid intra-cranial hæmorrhage. What, then, are the indications for trephining early in severe injury to the skull? They may be, I think, arranged under the two following heads:—

1. When there is reason to believe that there is rapid intra-cranial hæmorrhage going on with or without depression. This fact will generally be indicated by such symptoms as I have described in the third case, but a presumption may be afforded in favour of bleeding from the exact situation of the injury. For instance, if there be a fracture at the anterior inferior angle of the parietal bone, it is quite possible that the middle meningeal artery may be injured. This does occasionally happen, and should be kept in view.

2. When a foreign body has penetrated the skull and is

lodged in the brain, and cannot be removed without enlarging the opening. These are the indications for early trephining. But what, you will say, of stellate fractures, do these not present absolute indications for operating? In answer to this I would say that it is extremely questionable if they do. But granting that they do they come under this second head, for in these the presumption is that the inner table of the skull being shattered the fragments are driven in upon the membranes and are thus for all practical purposes foreign bodies which sooner or later will by their irritation cause inflammation of the membranes of the brain.

Gentlemen, I have touched upon various points of great interest in connexion with injuries to the head. It has not been possible to discuss these fully within the limits of one lecture. I have endeavoured to explain the more salient symptoms of the cases I have described to you and to draw what practical conclusions the facts fully warrant. I trust that what I have said will in some measure stimulate you to the study of these all-important affections.

## Lectures

ON

## DIGESTION.

*Delivered before the Royal Institution of Great Britain,*

By ARTHUR GAMGEE, M.D., F.R.S.,

BRACKENBURY PROFESSOR OF PHYSIOLOGY IN  
OWENS COLLEGE, MANCHESTER.

### LECTURE IV.

THE acid chyme, when it leaves the stomach, contains a large quantity of undissolved proteids, and of fat totally unacted upon; it also includes the starch that has remained unchanged by the action of the saliva, and undigested cellulose. It becomes mixed with the bile, which is to be regarded as an excretion to a great extent, and as a by-product of important actions going on in the liver. By its alkalinity it helps to neutralise the acid chyme, and thus to establish conditions favourable to pancreatic digestion; it usually contains no unformed ferment.

The principal remaining digestive juice is that afforded by the pancreas, which is one of the compound racemose glands, with a general resemblance to the salivary glands. Its tubular acini contain cells which in the fasting condition have very granular contents, together with an outer clear zone. When the gland has been in action for some time, after food has been taken, the contents of the cells are much less granular, and the clear zone increases in extent. The pancreatic juice is a secretion variable in quantity according as food has been ingested recently or not. It is almost *nil* during fasting, and becomes considerable almost as soon as food has entered the stomach. It attains a maximum about two hours after this time, being secreted in smaller quantities until about the sixteenth hour after food has been taken. It is markedly alkaline, the alkalinity being due to sodic carbonate, which is almost as important an ingredient here as hydrochloric acid in the gastric juice.

Pancreatic juice contains three if not four distinct ferments—pancreatic diastase, trypsin (a proteolytic ferment), a fat-decomposing ferment, often termed “emulsive” ferment, and also a milk-curdling ferment. The action of the diastatic ferment upon starch is exactly the same as that of salivary diastase, the ultimate product being dextrins and sugars (especially maltose.) This power is most important, seeing that in ourselves much starch arrives at the stomach unchanged, and in the herbivora the saliva is not diastatic at all.

Of trypsin, the proteolytic ferment, although it has not yet been prepared in a state of chemical purity, it may be said that it is not so exigent as pepsin in the conditions under which it acts. It will exert its transforming powers in a neutral, a very feebly acid, or in a definitely though not very intensely alkaline liquid. Trypsin seems to cause more profound changes even than pepsin, for after the peptones are formed, some of them appear to split up further into leucine,

$C_6H_{13}NO_2$ , tyrosine,  $C_9H_{11}NO_3$ ; the body indol,  $C_8H_7N$ , possesses a foul smell, which appears in the course of prolonged pancreatic digestion to be connected in its formation with the development of bacteria.

The administration of food which has already been partially digested by pancreatic ferments proves most valuable in certain cases, and relieves much suffering. This is to be noted in favour of pure scientific investigation, for when the experimental researches by which our knowledge of the action of the pancreas has been obtained were commenced, it was not at all obvious that they would lead to the relief of human suffering. The recent wide use of peptonised foods is not a little due to the researches in this direction of Dr. William Roberts, F.R.S., of Manchester.

To Claude Bernard is due the establishment of the fact that pancreatic juice emulsionizes and partially decomposes fats. Both pancreatic juice and minced pancreatic tissue are capable of emulsionising olive oil, which remains in the emulsified condition after standing many hours. The fats, as acted upon by pancreatic juice, are able to enter the lacteals of the small intestine. In an animal killed two or three hours after a mixed meal, the lacteals are found filled with a white liquid consisting very largely of emulsified fat. An argument drawn from comparative anatomy is of interest here. In the rabbit the pancreatic duct is not closely connected with the bile duct, as in many animals, but opens into the small intestine thirteen or fourteen inches below the bile duct; and, in correspondence with the function assigned to the pancreatic secretion, a rabbit killed some hours after a meal has milky chyle only in the lacteals of that part of the intestine below the entrance of the pancreatic duct.

Pancreatic juice further has a saponifying action upon neutral fats, decomposing them into glycerine and a fatty acid. This has been denied by some observers, but the failure to verify this action depends upon the readiness with which the fat-decomposing ferment of the pancreas is itself decomposed by acids. Therefore special precautions are requisite to prevent the destruction of this ferment in making experiments. The addition of a little carbonate of soda, to preserve the alkalinity, is necessary to retain the ferment in activity; otherwise it is killed or prevented from acting by the very acid which it forms. But under conditions which preserve the alkalinity of the digesting mixture, the saponification of fats under the action of pancreatic juice can be most satisfactorily observed.

There is, no doubt, a further ferment in the pancreatic juice, which has, like the gastric juice, the power of curdling milk or precipitating its casein. Thus, if to a neutral or even faintly alkaline emulsion of oil of sweet almonds and gum arabic there be added a sufficient quantity of a blue solution of litmus, and a few drops of a feebly alkaline, freshly prepared glycerine extract of pancreas, and the mixture be rapidly raised to the temperature of the mammalian body, the reaction changes almost instantly from alkaline to acid, as shown by the transformation of the blue colour of the mixture to red. This acidification of neutral fats by the pancreatic juice, which on many grounds is to be connected with an unformed ferment, is doubtless associated with the emulsifying powers of the pancreatic juice, though it is doubtful whether the ferment directly influences the emulsionising process as is implied by the term given to it by Claude Bernard of “ferment emulsif.”

As to the absorption of the products of digestion, that subject does not formally enter into the present course; but it may be said, briefly, that water, soluble salts, peptones, and sugars are absorbed directly into the blood for the most part, while the fats enter almost exclusively into the lymphatics.

The lectures were illustrated not only by diagrams, but also by slides exhibited with the aid of the electric light, and by numerous typical and instructive chemical experiments.

At the second diet of a Sheriff and Jury Court held at Dumfries last week a student of medicine was charged with culpable homicide, in so far as, on April 9th last, having been called to attend the wife of a hostler who was suffering from cramp in the stomach, he administered to her, by hypodermic injection, from twelve to fifteen minims of solution of morphia, whereby death resulted in about fourteen hours afterwards. A plea of guilty was tendered, but it was pleaded that the fatal consequences resulted from an unfortunate mistake. A fine of £20 was imposed, the alternative being a month's imprisonment.

## ON DOCHMIUS DUODENALIS (SCLEROSTOMA VEL ANCHYLOSTOMA DUODENALE) AS A HUMAN PARASITE IN INDIA.

By J. F. P. McCONNELL, M.B.,

PROFESSOR OF PATHOLOGY AND CURATOR OF THE PATHOLOGICAL MUSEUM,  
MEDICAL COLLEGE, CALCUTTA.

IN Professor Cobbold's recently published treatise on the "Entozoa of Man and Animals," pp. 212-16, a very interesting account is given of the observations made by Griesinger and Wücherer with respect to the geographical distribution and pathological importance of this small nematoid worm. It has been found "by Bilharz and Griesinger in Egypt; by Wücherer, Dr. Moura, Dr. Tourinho, and other physicians in Brazil; by Monestier and Grenet in the Comoros; and by Rion Kérangel in Cayenne." In commenting on "the wide separation of these several localities," Wücherer ventures to predict that "anchylostomes, if duly sought for, will be found in many other countries." This has already been verified in some parts of Europe, as, for example, the numerous instances reported of the infection by anchylostomes

of workmen engaged in the St. Gothard tunnel; and as regards India, the present paper will prove that these parasites are far from being uncommon amongst natives—at least, amongst the natives of Lower Bengal. The description of the anatomical structure of the dochmius given by Cobbold<sup>1</sup> renders its identification easy:—"The males measure  $\frac{3}{8}$ ", or rather more, whilst the females extend to very nearly  $\frac{1}{2}$ " (12 mm.). The head is pointed and tapering, and bent forward, having the mouth directed towards the ventral aspect. The oral opening is armed with four asymmetrically disposed, unequal-sized, horny, conical, converging teeth. The neck is continuous with the cylindrical body, which is  $\frac{1}{8}$ " in thickness. The body terminates in a straight cone-shaped, or rather sharply pointed, tail in the female, the caudal extremity of the male ending in a partially inflexed blunt point. In the male there is a cup-shaped, bilobed bursa, the membranes of which are supported by eleven chitinous rays, ten being simple, whilst the median, or odd one, is bifurcated at the summit. The mode of reproduction is viviparous. Adult males and females occur in the proportion of one of the former to three of the latter."

This description may be supplemented by certain particulars, the results of careful examination of numerous specimens in my possession, from which, also, the drawings in the accompanying woodcut have been made.

Fig. 1.—Female dochmius,  $\times$  abt. 6. Fig. 2.—Male dochmius,  $\times$  abt. 6. Fig. 3.—Anterior portion of female worm,  $\times$  35; showing the mouth (a) and the oesophagus (b). Fig. 4.—Posterior portion, or tail, of female,  $\times$  35, with termination of intestinal canal at a. Fig. 5.—Caudal bursa of male,  $\times$  35, with pronged chitinous rays, &c.

The average length of the female sclerostomata in my possession is  $\frac{1}{2}$ " (14 mm.), and of the males  $\frac{3}{8}$ " (11 mm.). The breadth of the former, at the thickest part (about the middle of the body) is about  $\frac{1}{8}$ "; of the latter, about  $\frac{1}{16}$ ". The head is not strictly "pointed and tapering," but rounded or somewhat square-shaped, and abruptly truncated. The mouth (Fig. 3, a) is provided with three or four irregular, hard, horny teeth; it measures in the female  $\frac{3}{8}$ ", in the male  $\frac{1}{4}$ ". The oral orifice leads into a pharynx and bulbous oesophagus (Fig. 3, b), very distinct in both males and females, and measuring in the latter  $\frac{1}{8}$ " in length by  $\frac{1}{16}$ " in greatest width. The muscular structure of this portion of the alimentary canal is particularly well marked, and probably forms a powerful suction-apparatus. To the oesophagus succeeds a simple intestine, which terminates in an anal aperture a short distance ( $\frac{1}{16}$ " from the tail in the female (Fig. 4, a), and on the under surface of the caudal bursal expansion in the male. The rest of the body of the worm is occupied by the reproductive tubules and glands, the former of which, especially in the female, have a highly convoluted outline, and very dark granular contents. The caudal bursa in the male dochmius measures about  $\frac{1}{8}$ " (Fig. 5). The chitinous rays which it supports vary in number from ten to twelve; the majority are double, like the prongs of a fork; one or two may be simple or solitary. This evidently constitutes a prehensile organ, and is the chief distinguish-

ing peculiarity (apart from the difference in size) between the male and female sclerostome. Lastly, the body of the worm has a distinct double contour—a transparent interval of from  $\frac{1}{16}$ " to  $\frac{1}{8}$ " existing between the peripheral outline and the dark central structure of the parasite. This transparent portion is composed of muscular fibres arranged in very distinct transverse bundles.

The first specimens of this nematoid observed by me in this country were found on January 6th, 1879, adhering to the mucous membrane of the jejunum of a native (Hindu) male, aged twenty-five, who had died in the Medical College Hospital from chronic dysentery. I mistook them for thread worms, though puzzled to account for their presence so high up in the intestine. On placing some of them, however, under the microscope, the distinctive peculiarities which separate them from the oxyuris vermicularis were readily recognised. Since this period I have met with sclerostomata in nineteen other bodies examined in the dead-house. In some only four or five worms, in others more than fifty were found in the bowel or its contents.

With respect to the pathological significance of this entozoon, Griesinger has described a form of "anæmic chlorosis" in Egyptians, and Wücherer a similar condition (under the designation of "hypœmia") in Brazilian sub-

<sup>1</sup> Loc cit., p. 211.

jects, which both these observers attribute directly to the presence of these worms, and their action as "veritable blood suckers." More recently a similar rôle has been assigned to these parasites in connexion with the epidemic disease which proved so fatal to some of the workmen employed in the construction of the St. Gothard tunnel, and was referred to in an annotation in THE LANCET on April

3rd, 1880, p. 535, headed "Anchylostomosis." There is still, however, some difference of opinion with respect to this interesting question, and, for this reason, I have taken great care to record carefully the causes of death, and the presence or absence of anæmia in all the cases that have come under my own observation. These details, with others, are exhibited in the accompanying table.

TABLE OF CASES OF DOCHMIUS DUODENALIS IN THE HUMAN BODY, WITH NATURE OF DISEASE, PRESENCE OR ABSENCE OF ANÆMIA, ETC.

No.	Race &c.	Sex.	Age.	Disease.	Where found.	Anæmia present.	Remarks.
1	Native (Hindu)	Male	25	Chronic dysentery	Jejunum	Yes	Worms found adherent.
2	Native (Mahomedan)	"	18	Acute dysentery	"	No	Distoma conjunctum in bile-ducts of liver.
3	Native (Hindu)	"	—	Erysipelas	Duodenum and upper part of jejunum	No	One whipworm (trichocephalus) and one threadworm (oxy. vermicularis) found in large intestine. No bowel lesion.
4	"	"	12	Malarial anæmia and exhaustion	"	Yes	"
5	"	"	40	Chronic bronchitis	"	No	"
6	"	"	30	Remittent fever	"	No	"
7	"	"	32	Malarial anæmia and dysentery	Free in contents of small intestine	Yes	"
8	"	"	28	Acute cerebro-spinal meningitis	Jejunum	No	No bowel lesion.
9	"	"	40	Dysentery	Jejunum and upper part of ileum	Yes	—
10	"	"	25	Pneumonia	"	No	No bowel lesion.
11	"	"	26	Traumatic tetanus	"	No	"
12	"	"	26	Cirrhosis of liver &c.	"	Yes	Small puncta where worms adhered.
13	"	"	26	Morbus cordis	Duodenum and upper part of jejunum	No	Worms found adherent.
14	"	"	35	Acute dysentery	Free in contents of small intestine	No	—
15	"	"	30	Pyæmia after compound fracture of the foot	"	No	No bowel lesion.
16	"	"	30	Cirrhosis of liver	Duodenum	No	"
17	"	"	18	Dysentery and cirrhosis of liver	Jejunum	Yes	"
18	"	"	30	Acute dysentery	Duodenum and upper part of jejunum	No	Worms found adherent.
19	"	"	20	Chronic dysentery	Jejunum and upper part of ileum	Yes	Worms found adherent, and when detached and placed in water, exhibited lively movements.
20	"	Fem.	25	Chronic dysentery and splenic anæmia	Jejunum	Yes	Worms found adherent.

While anæmia was a prevailing element in nearly half (8 out of 20) of the cases in which sclerostomata were found, yet it seemed to me that this condition was, in these cases, more directly attributable to dysentery and malarial complications than to the presence of a varying number of these parasites; and, on the other hand, in more than half the number (12 out of 20) not only was there no anæmia, but a positive hyperæmic condition of almost all parts and tissues of the body, as is the rule in acute or sthenic diseases, such as pneumonia, erysipelas, cerebro-spinal meningitis, remittent fever, &c. Not only, therefore, was there no anæmic condition of parts discovered after death in the majority of these cases, but the very nature of the fatal diseases precluded the existence of this condition during life. Hence, while it may readily be conceded that in a certain proportion of the cases now reported the anæmia might partially be attributable to the depletion resulting from the presence of sclerostomata, in the majority their existence was not associated with this state; and, certainly, no facts in this connexion have hitherto tended to show that anything like a specific hypoxæmia or chlorosis occurs in the natives of this country, which can be traced even indirectly to this cause.

In no instance has blood in any quantity been found in the small intestine, and, except in dysenteric cases (and then usually with mucus and other inflammatory products), the same may be said with regard to the colon. A point or minute puncture is observed when an adhering dochmius is detached from the mucous surface of the bowel, and occasionally small red puncta in the duodenum or jejunum have indicated the site of attachment of these parasites, but more frequently the lining membrane of the intestine has been found quite healthy and free from all pathological changes. I have, hitherto, failed to find these worms in the evacuations during life, nor do I know of any specific symptoms by which their existence is to be diagnosed. My opinion is that their presence is to be regarded

in the majority of cases as purely accidental, and their relation to any special disease a coincidence. The lower classes of natives in this country are by no means clean feeders or careful as to the quality of the water they drink, and hence are very frequently infected with intestinal worms, particularly the round worm. The presence of sclerostomata may be attributed to the same causes, and I am inclined to believe that the prevalence of these worms is not very much less common than that of the lumbricus in this class of individuals. It may here be mentioned that up to the present time all the cases in which I found these parasites have been natives, and, with one exception, males. This circumstance may perhaps be due to the fact that comparatively few bodies of native females are brought to the post-mortem room at the Medical College Hospital. In not a single instance has the worm been discovered in a European, Eurasian, &c. The first two of my cases (see table) show that the occurrence of sclerostomata is not incompatible with the existence of other entozoa in the same "host."

In conclusion, I would direct attention to the fact that in the majority of the cases these worms were met with in the jejunum, or even lower down the intestinal canal. In some instances this might have been due to the contents of the bowel being squeezed downwards before the latter was laid open; but in the majority this was not the case, the parasites being found adherent. This circumstance seems of some importance, since one of the specific names of the dochmius, or sclerostoma, is derived from a particular portion of the intestinal canal supposed to be its usual habitat.

THE Royal Commission on Metropolitan Sewage Discharge met on Tuesday at 20, Great George-street. There were present—Lord Bramwell, F.R.S. (in the chair), Sir John Coode, Professor A. W. Williamson, F.R.S., Dr. De Chaumont, F.R.S., Dr. Stevenson, Mr. James Abernethy, F.R.S.E., and Dr. W. Pole, F.R.S. (secretary).

## THE QUESTION AS TO THE IMPORTANCE OF UTERINE DISPLACEMENTS.

By GRAILY HEWITT, M.D., F.R.C.P.

THIS is a question which is not by any means settled or decided by the various statistical data which have been of late adduced on the subject, the latest of all being the statistics recently published in the *Archiv f. Gynæk.* (vol. xix., 1882) by Dr. Vedeler, and commented on in THE LANCET of June 24th. There are two methods of procedure in order to obtain conclusions as to the value or importance of uterine distortions and associated displacements.

A. One is to examine healthy subjects and ascertain the position and shape of the uterus. But it must be certain that these subjects are healthy and do not present symptoms which can be traced to the uterus. This implies an accurate and full knowledge of what the symptoms are which are traceable to disturbed or disordered conditions of this organ.

B. Another is to observe carefully the history, course, symptoms, and effects of particular changes in the uterus, and to procure numerical evidence as to the frequency of conjunction between the particular pathological change and the symptom and effect resulting therefrom. Further to test the effect of treatment capable of removing the pathological condition in also putting an end to the symptom or effect supposed to be due to it. This implies a long course of experimental observation of cases.

Dr. Vedeler's statistics—an attempt to solve the question by the A plan of investigation—by no means comply with the necessary scientific conditions. In the first place Dr. Vedeler starts with the statement that most gynaecologists over-estimate the importance of uterine displacements (implying a bias of judgment on his part to begin with). By a diseased condition, Dr. Vedeler understands that symptoms are complained of which can be traced back to the pelvic organs, or which point to organic changes. He, however, expressly states (though this was not mentioned in THE LANCET commentary on June 24th) that dysmenorrhœa is not included in these symptoms.

But it would appear that Dr. Vedeler must have excluded many other symptoms as well as dysmenorrhœa. It is to be presumed that the patients examined were really patients, and that they made some complaint sufficient to justify the making of the examination. Thus it is stated that 466 virgins were examined, and that of these 332 were found to have ante- or retroflexion of the uterus; of these 332 ante- or retroflexion (virgin) cases the uterus was found to be "sound" in 296 cases, and "diseased" in 36 cases. Now, it may be properly inquired how it happened that the 296 sound cases came to be examined. Dr. Vedeler appears to have found no inflammatory lesions in these cases; he only found the ante- or retroflexion. But he proceeds to draw the very remarkable inference that these 296 patients were "sound"; and his whole conclusions on other displacements, as well as ante- or retroflexions, are based on a similar foundation. Dr. Vedeler argues as if the 296 cases examined were "sound." The inference is that they were not so, or they would not have presented themselves for examination.

I have alluded to "dysmenorrhœa," which Dr. Vedeler (most erroneously, as I consider) excludes as a symptom of uterine disease. There is another class of symptoms of which he makes no mention, but from what I know of the subject I feel certain that very many of the 296 supposed sound cases presented the symptoms in question.

Having been at some pains to arrive at a knowledge of patients' views on the subject of "suffering" in cases of uterine disease, I have come to the conclusion that much misapprehension prevails in reference thereto. The fact is that patients complain in the large majority of cases of "sufferings" which are very often entirely passed over or considered trifling by those who investigate their condition. Leucorrhœa, dysmenorrhœa, menorrhagia, &c., these symptoms are generally noted, and very properly so, but the inconvenience, discomfort, or pain attendant on locomotion, which I have described as uterine "dyskinesia," is a symptom so generally to be noted in some form, and it assumes an importance so great in the estimation of the patient in very many instances, that it stands at the head of the list of symptoms due to uterine disorder in regard to its

frequency and clinical importance. The connexion between this symptom and the various forms and degrees of uterine flexion and displacement is easily capable of substantiation by clinical data, and about the truth of this there can be no manner of doubt.

Nausea or vomiting is also a symptom very frequently constituting one of the "sufferings" of patients affected with uterine distortion. This symptom has much attracted my attention and investigation. Engelmann of St. Louis has expressed views on this subject identical with my own.

Taking these two symptoms, uterine dyskinesia and nausea or vomiting alone, and testing their connexion with flexion of the uterus, observing the marked effect produced by treating the flexion in removing the "sufferings" in question, a mass of evidence is adduced showing the great "importance" of the flexion in such cases. But it does not follow, nor logically would it be expected to follow, that all cases of flexion shall be attended with these symptoms. My contention is that these particular symptoms frequently exist and are overlooked, and before we can consider any individual with a flexed uterus as "sound," there must be clear evidence of absence of such symptoms. It by no means results, even then, that we shall be in a position to admit the "soundness," for further investigation may entirely disprove it.

In reference, therefore, to a vast number of cases considered by Dr. Vedeler to be "sound," so far as the uterus is concerned, it is necessary to inquire whether these supposed sound individuals complained of discomforts attending locomotion or of sickness. In all probability many of them did so complain, or would have done so had they been interrogated. Dr. Vedeler has himself excluded one set of symptoms, dysmenorrhœa, as he apparently does not consider this a symptom of uterine disease at all; and we are at present left to the conclusion that this symptom was present in some, at all events, of the cases which he classes as free from uterine disease. Until dysmenorrhœa is dissociated with uterine flexions—a dissociation which has not yet been effected, though efforts have been made in this direction—this mode of dealing with the symptoms in question renders Dr. Vedeler's statistics of little value as proving the conclusions he proceeds to draw from them.

I have in the foregoing remarks simply pointed out reasons for distrusting the scientific value of Dr. Vedeler's data. No doubt these data have a certain value, and truth will be advanced by a thorough sifting of the question. It will not, however, be found so easy as it has been supposed to be to account for clinical facts by ignoring the influence and importance of uterine distortions and displacements. Sterility, tendency to abortion, various serious reflex nervous disturbances—these and other clinical phenomena have also to be dealt with and satisfactorily explained.

Berkeley-square, W.

### REPORT OF

## ONE THOUSAND CASES OF SMALL-POX IN WEST HAM UNION HOSPITAL.

By J. MOIR, L.R.C.P. EDIN.,  
MEDICAL OFFICER.

THE Small-pox Hospital of the West Ham Union was opened for patients in February, 1877, and consequently has been now five years in operation. At first the accommodation was very limited, being only suited for 20 patients, in two small wards under one roof. This continued for two years, and during that time 493 patients were treated, and considering the limited space and conveniences very good work was done there. At the end of that time, by the death of the former medical officer, I succeeded to the appointment. The two old wards were immensely improved in every respect at considerable expense, and a year afterwards two new wards were built in separate blocks at right angles to the old wards, capable of receiving 30 more patients, 18 males and 12 females, experience teaching that the number of the former was greatly in excess.

I mention this chiefly to show that I do not myself claim credit for the very considerable reduction of the mortality in the second 500 cases as compared with the first, as the great

improvement in the hospital itself sufficiently accounts for that; and considering that of the 1000 cases rather more than 400 have been crowded into the last year, and rather less than 600 in the four previous years, with a remarkable reduction in the rate of mortality, it speaks well for the new buildings, and consequently increased staff, that they have done their work so well.

The following table shows the different districts of the West Ham Union from which the cases have been received, with the total number from each district, and includes 11 from another union, St. George-in-the-East, received last spring, but soon discontinued for want of room for our own cases.

TABLE I.

District.	No. of cases.
1. Canning Town ... ..	337
2. Stratford ... ..	222
3. Plaistow ... ..	199
4. Leytonstone ... ..	80
5. Walthamstow ... ..	44
6. East Ham ... ..	33
7. West Ham ... ..	31
8. Silvertown ... ..	16
9. St. George-in-the-East ... ..	11
10. Woodford ... ..	11
11. Wanstead ... ..	9
12. North Woolwich ... ..	5
13. Little Ilford ... ..	2
	1000

From this it will be seen that the parish of West Ham alone (which includes Canning Town, Stratford, Plaistow, West Ham, and Silvertown) has contributed 805 of these cases, all the other parishes in the union together only 184, and St. George-in-the-East 11. This is of course accounted for by its proximity to London and its completely urban character, the other parishes being chiefly, if not altogether, rural, and with a less population all put together than that of West Ham alone, which is now close on 130,000.

The mortality of the cases is shown as under:—

TABLE II.

First 100 cases ... ..	23 deaths
Second " ... ..	21 "
Third " ... ..	16 "
Fourth " ... ..	18 "
Fifth " ... ..	17 "
Sixth " ... ..	8 "
Seventh " ... ..	23 "
Eighth " ... ..	13 "
Ninth " ... ..	11 "
Tenth " ... ..	13 "
	163 "

From this table we see that the total number of deaths was equal to 16.3 per cent., and dividing them into two groups of 500 each for the reasons I have already stated, it will be seen that in the first 500 cases 95 died or 19 per cent., whilst in the second 500 cases 68 died, 27 less than in the first group, or 13.6 per cent.; this result, as will be seen from the table, is owing to the great mortality in the seventh hundred, chiefly, I believe, from unavoidable overcrowding, as many as fourteen admissions a week occurring, and the numbers in the hospital being for a considerable time over the accommodation, for two or three months in the early part of the year being as many as from 55 to 60, and on one occasion by making up a bed in my consulting room 61. Notwithstanding, the improvement is equal to 5.4 per cent., which is very gratifying. It will be also noticed that the number of deaths in the first hundred cases is the same as that of the seventh, 23, the one occurring in 1877, the other in 1881; that is to say, in each case at the beginning of an epidemic, when the cases are always worst. In the latter case I may say that four were brought in dying, and lived less than twelve hours after admission, eight were hæmorrhagic cases and all died, one was a case of primiparous tedious labour, and died from exhaustion forty-eight hours after delivery. I have little doubt the history of the first 100 cases is somewhat similar. In one case of labour which happened in the hospital the child was born alive and sent home, the mother recovered and left the hospital a month after, and is

still in good health; the infant took small-pox twelve days after birth and died in three days.

The mortality is very greatly increased by the unfortunate and lamentable ignorance and prejudice respecting vaccination. I cannot help thinking that West Ham is exceptionally unfortunate in this respect, as will be seen from the following table showing the number of vaccinated, unvaccinated, badly vaccinated, and revaccinated (badly vaccinated being almost equivalent to unvaccinated).

TABLE III.

	Vac- cinated.	Unvac- cinated.	Badly vac- cinated.	Revac- cinated.
First 100 ... ..	70	13	15	2
Second " ... ..	84	12	4	0
Third " ... ..	78	13	6	3
Fourth " ... ..	81	9	8	2
Fifth " ... ..	81	9	7	3
Sixth " ... ..	80	9	7	4
Seventh " ... ..	73	18	7	2
Eighth " ... ..	84	11	3	2
Ninth " ... ..	82	13	3	2
Tenth " ... ..	79	10	10	1
	792	117	70	21
	1000			

Here we find that out of 1000 admissions, 117 were unvaccinated and 70 badly vaccinated, practically 187 were unprotected, which is a most alarming, and, as we shall see from the following table of mortality under each heading, a frightfully fatal state of matters as regards these unprotected cases.

TABLE IV.

Died in	Vac- cinated.	Unvac- cinated.	Badly vac- cinated.	Revac- cinated.	Total deaths.
First 100 ... ..	9	8	6	0	23
Second " ... ..	15	5	1	0	21
Third " ... ..	6	9	1	0	16
Fourth " ... ..	13	5	0	0	18
Fifth " ... ..	14	4	0	0	18
Sixth " ... ..	3	3	1	0	7
Seventh " ... ..	8	10	5	0	23
Eighth " ... ..	5	6	2	0	13
Ninth " ... ..	6	5	0	0	11
Tenth " ... ..	5*	4	3	0	13
	85	59	19	0	163

\* And 1 small-pox and vaccination concurrently.

From this table, then, we find that from amongst 792 vaccinated 85 died, or a mortality of 10.7; of the 21 revaccinated none died, in striking contrast with the 59 deaths in the 117 unvaccinated cases, a percentage of 50.4, and of the 19 deaths in the 70 cases of badly vaccinated, a percentage of 27.1. Or if we take the 792 vaccinated cases and the 21 revaccinated, 813 cases with their 89 deaths, and compare them with the 117 unvaccinated and 70 badly vaccinated, 187 cases with their 78 deaths, we find a still stronger plea in favour of vaccination than any sentimentalism, prejudice, or ignorance can bring on the other side. In the case of the vaccinated, we find that the mortality is 10.4 per cent., in that of the unvaccinated 41.7 at best. This means a saving of 31 lives in every 100 in favour of the vaccinated. Nothing more requires to be said on this point, but I believe that efficient revaccination affords total immunity from death from small-pox, as the annals of the London and other small-pox hospitals conclusively prove. Some cause must have arisen to create such a lessened mortality from this disease as we find depicted in the Report for 1880 of Dr. Tripe of Hackney to the Local Sanitary Authority, and I agree with him that that cause can only be vaccination; revaccination would prove still more efficient. Dr. Tripe gives the following statement of the annual number of deaths from small-pox in London per 100,000 inhabitants:—

Before vaccination.	After vaccination.
7 years 1829-35 ... ..	189
20 " 1860-79 ... ..	417
30 " 1728-57 ... ..	426
10 " 1771-80 ... ..	502
	10 years, 1871-80 ... .. 48;
	or 8 years, 1873-80 ... .. 17;
	—i.e., after the Compulsory Vac- cination Act came into force.

Or take thirty-three years of vaccination, 1839-1872, 40. Of course anti-vaccinationists may have some sort of answer to

these figures from the Hackney Report, but I fail to see what it can be.

That there should have been 21 cases of small-pox admitted into the West Ham Union Small-pox Hospital after revaccination may seem somewhat at variance with the above remarks; from Table III. it will be seen that 10 of these were in the first 500 cases, and 11 amongst my own cases. Of the first I cannot speak positively, but they were probably like my own; in only one case did I find eight good marks, in none of the others more than four marks, and in some only three. There is reason, then, to think that if the revaccination were genuine, which is highly probable, the primary vaccination must have been very bad, or not have taken at all, but I have no doubt that in all but one case the original vaccination was, to say the least of it, inefficient. Two cases were reported, one in each group of 500, to have had small-pox twice. This is doubtful, but I had a case of small-pox last summer in a child where the mother wished to be revaccinated along with the rest of the household; she is rather markedly pitted with small-pox, and said she had had it twice, twelve and eight years ago, and the pitting was caused by the first attack. I vaccinated her in three places, and they all took well. This is a remarkable instance of idiosyncrasy, which is occurring every now and again, and is difficult to explain, except by the great natural predisposition of certain people to certain diseases, and will account for some cases of small-pox, even after good revaccination; however, only one of my eleven cases was of that character, and in any case the whole twenty-one cases reported as revaccinated recovered.

In the following table is an abstract of the number of admissions and deaths of males and females under and over sixteen years of age; to those acquainted with union work this division will require no explanation.

TABLE V.

	MALES.				FEMALES.			
	Under 16 yrs.	Died.	Over 16 yrs.	Died.	Under 16 yrs.	Died.	Over 16 yrs.	Died.
First 100	14	2	48	15	15	3	23	3
Second ditto	11	2	51	16	17	1	21	2
Third "	26	5	39	7	19	2	16	2
Fourth "	11	5	45	7	21	3	23	3
Fifth "	15	2	50	12	12	0	23	3
Sixth "	26	1	37	3	19	0	18	4
Seventh "	18	4	39	9	20	4	23	6
Eighth "	19	1	40	9	25	0	18	3
Ninth "	25	2	38	5	22	3	17	1
Tenth "	35	3	32	4	15	1	18	5
Totals ..	200	27	417	87	185	17	198	32

Total—1000 cases; 163 deaths.

The total number of the unvaccinated cases under sixteen years of age was 48, and over sixteen 69—total 117, of whom we have seen that 59 died. The admissions under five years of age were 45, ranging from two weeks old, not counting the infant born in the hospital where the mother had been admitted the week before with confluent small-pox. There were 5 cases over sixty, and 1 over seventy years of age. From this table it will appear that there were 200 cases of males under sixteen years of age with 27 deaths, being a percentage of 13.5. Over sixteen years of age 417 male cases and 87 deaths, being equal to 20.8 per cent. Amongst females under sixteen years there were 185 cases and 17 deaths, nearly 9.2 per cent., and of females over sixteen 198 cases and 32 deaths, being just about 16 per cent. Altogether there were in the 1000 cases 617 males and 383 females. Those under sixteen show a less mortality than those above sixteen years of age, and females considerably less than males in both classes, the ratio being 114 deaths amongst 617, a mortality of 18.4 per cent., whilst there were only 49 deaths amongst the 383 females, or 12.7 per cent.; or 3 male deaths to each 2 female deaths. The average mortality of the 114 male to the total of 163 deaths is 70 per cent., and the female 30. During the whole time the hospital has been opened and in the whole 1000 cases this proportion has remained pretty constant, and it would appear from the experience of this Union that females are less susceptible to small-pox and to death from small-pox than males are.

I have stated that the hospital was opened in February,

1877, and in the following table is shown the number of deaths in the 1000 cases for each month.

TABLE VI.

Monthly Mortality from March, 1877, to December, 1881.

	1877.	1878.	1879.	1880.	1881.	Total.

Nov.	3	"	0	0	2	5
Dec.	2	"	No patients	1	2	5
Totals	55	40	3	1	64	163

It will be seen from the above table that 1877-78 was an epidemic time for small-pox in West Ham, as there were 493 cases in hospital and 95 deaths. In the two years 1879-80, when I first took charge of the hospital, there were only 48 cases and 4 deaths; but in 1881 alone there have been 459 admissions and 64 deaths, the mortality being 13.9 per cent. for the year. From present appearances I am of opinion that the epidemic of small-pox, at least in West Ham, will run through another year, 1882, and I would strongly recommend as the only means of checking the disease the most efficient vaccination and revaccination; I should then have no fear of a successful result, and should feel certain of as great or greater immunity for West Ham Union than even in 1879-80.

## ECTROPION OF BOTH EYELIDS OPERATED ON BY WOLFE'S METHOD.

By G. H. HUME, M.D.,

SURGEON TO THE NEWCASTLE-ON-TYNE INFIRMARY.

In the following case the plastic operation by transportation of skin from the cornea was tested under very unfavourable circumstances. In the upper eyelid the operation gave entirely satisfactory results. In the lower lid, though the operation was thrice repeated, the result in the end was only partially successful. The case therefore yielded opportunity for observing, on the one hand, the conditions which favour the success of the method, and on the other, those which are apt to cause failure.

J. M.—, a young woman aged twenty-four, was admitted into the Newcastle-on-Tyne Infirmary in March, 1881. Nine months previously the right side of her head and face had been severely burned. At the time of admission her condition was a very distressing one. The forehead had become covered by a thin cicatrix adherent to the bone. The skin of the temporal region had been destroyed and the raw surface was not yet quite healed. Across the infra-orbital region to the side of the nose and down to the upper lip the skin had in great part been replaced by cicatrix. The upper eyelid had been almost completely destroyed, so that the conjunctiva was everted and bound down to the supra-orbital ridge. The lower eyelid was also everted and attached to the bone. As a consequence of exposure of the eye destructive inflammation with ulceration of the cornea had set in, and appeared to be advancing rapidly. The ectropion of the upper lid was first operated on. In performing the operation the details given by Dr. Wolfe were scrupulously followed. The remains of the lid were freed from the bone, and the conjunctiva turned down so that the edge lay in contact with the everted edge of the lower lid. The margins of both lids were pared and stitched together with strong silk sutures. A pattern of the gap which had been made by freeing and turning down the conjunctiva was next taken with a piece of lint, and a piece of skin cut to the shape of this pattern, but somewhat larger, was raised from the forearm. This piece of skin was next prepared by carefully removing from it the subcutaneous tissue till the white surface of the corium was reached. It was then laid in posi-

tion and its margin stitched to the edge of the gap with fine silk suture. After being treated for a few seconds by the application of lint soaked in hot water, a dressing of several folds of warm water lint was applied, and both eyes were bandaged. The dressings were removed on the third day, the transplanted skin was then found to have changed its ashy-white dead appearance for a bluish-red hue. It had become adherent with the exception of a very small portion of its upper and outer edge. As the result of this operation a well-shaped eyelid was formed with complete correction of the conjunctival eversion. Under shelter of the new lid the condition of the eye rapidly improved. The inflammation subsided without treatment, and the corneal ulceration healed.

The patient was readmitted on June 29th to have the lower lid operated on. The proceeding was the same as in the upper lid, but it entirely failed. In October the operation was repeated, with the result that a portion of the flap adhered, producing a partial though decided improvement.

A third trial was made in December. On this occasion the lids were not stitched together; and in order to restrain movement as far as possible, and also to obtain exact contact between the surfaces, a piece of fine sponge was used as a dressing. On the third day the whole of the transplanted skin seemed to have become vitalised; subsequently suppuration set in around the margin, and led to the reparation of the greater portion. A part at the inner angle remained adherent, and seemed to some extent to reduce the eversion.

An explanation of the different results obtained in the upper and lower lid appears to be offered by the following considerations. The principle of the operation consists in the vascularisation of a piece of skin placed in a vascular, non-suppurating bed. It is essentially a process of primary union. That this should take place the necessary conditions are: the removal from the bed of all cicatricial tissue (tissue of low vitality); the removal from the flap of all subcutaneous tissue which would offer a hindrance to the advance of bloodvessels into the corium; and lastly, freedom of the part from movements which would interfere with the process of adhesion. In all points the conditions were favourable in the upper lid. Scarcely any part of the lid remained save the conjunctiva. When this was turned down the external surface of it formed a highly vascular bed, free from cicatricial tissue, and after the operation there was no difficulty in preventing movement. In the lower lid, on the other hand, it was impossible to remove altogether the bands of cicatricial tissue; and there were constant twitchings of the lid, which could not be restrained, and which appeared to be in great part the cause of the repeated ill-success of the operation.

#### NOTES OF A CASE OF

### UNUNITED FRACTURE OF THE LEFT FEMUR; OPERATION; RECOVERY.

By J. C. RENTON, M.B. EDIN., F.F.P.S. GLASG.,  
EXTRA SURGEON TO THE DISPENSARY OF THE WESTERN INFIRMARY,  
AND ASSISTANT-SURGEON TO THE EYE INFIRMARY, GLASGOW.

J. M.—, aged thirty-three, was admitted to the Western Infirmary on July 26th, 1881, and came under my care during the absence of Professor George Buchanan. In November, 1880, he had his left thigh bone broken by direct violence at Pitzburg, but no union took place, and he came to this country early in July, 1881. On examination the left femur was found to have a false joint in the middle third, giving the impression that there had been an oblique fracture, the upper end of the lower fragment being inside and posterior to the lower end of the upper fragment; the limb was two inches shorter than the right, but on extension it was only one inch, the two fragments could not be brought into apposition, the muscles of the limb were much atrophied, and no apparatus enabled the man to walk with any comfort. The following operation was performed on August 8th:—Having made an incision six inches long on the outer side of the limb, the broken ends of the bone were exposed, and were found covered by a cartilaginous material; bands of ligamentous tissue extended between the fragments, the lower one being fixed posteriorly by dense tissue. Half an inch was sawn off the fractured ends, which were turned out-

wards to enable the saw to be more easily applied, and the adhesions separated. The cut surfaces of bone could now be held in contact, but whenever the support of the finger was removed they slipped; to obviate this I drilled two holes with a surgical brace through the divided ends obliquely, and passed a steel peg six inches long and the eighth of an inch thick through the holes; this held the surfaces in contact. At one end of the peg there was a flattened head, which lay at the lower angle of the external wound, into which a drainage-tube was introduced, stitches applied, and Lister's antiseptic dressing used. The limb was placed in a box splint, specially made for the purpose, with an inside lateral splint.

Oct. 7th: The temperature has remained normal since the operation; the dressings were changed six times, the drainage-tube being removed at the fourth dressing, a fortnight after the operation, when the wound was found healed except at the upper and lower angles.—16th: The peg was found loose, and was removed, and as the patient could raise the limb from the bed, and on manipulation the bone seemed quite solid, the splints were not reapplied, but plaster-of-Paris bandages were used to form a firm case for the leg and thigh, and on the 19th the patient was dismissed. On measuring his limbs previous to departure, a difference of one inch was noted.

March 2nd, 1882: Patient now walks without any stick, and expresses himself as perfectly well.

Remarks.—Owing to the displacement in this case any simple subcutaneous operation would have been useless, so that it was decided to expose the broken femur, and either introduce two pegs, according to the method recommended by Dieffenbach, or to adopt the plan detailed above. The result fully justifies the somewhat hazardous procedure, and the entire absence of any constitutional disturbance is another illustration of the value of Lister's antiseptic method.

#### GUY'S HOSPITAL.

##### CASES OF ABDOMINAL SURGERY.

(Under the care of Mr. BRYANT.)

CASE 1. *Hydatid of Liver; Paracentesis twice; Relieved.* (Notes by Mr. Masters.)—Mary Ann L—, aged twenty-two, was admitted on Oct. 30th, 1881, into Lydia ward. The patient was married, and had had one child five months before. About three years previously she first experienced morning sickness and faintness as if pregnant, although at this time she was not married. About the same period she noticed a small hard lump in the right lumbar region; this gradually increased, and was taken for ovarian disease. In July, 1880, she was seen by Mr. Bryant, who, considering that she was only recently married, and that the enlargement might be due to hydatids, recommended that no operative interference should then be resorted to. On admission the patient was in good general health, and the tumour only caused mechanical inconvenience. Measurements: Ensiform cartilage to umbilicus,  $7\frac{1}{2}$  in.; left anterior superior spine to umbilicus, 8 in.; right ditto,  $7\frac{1}{2}$  in. On Nov. 4th she was placed under chloroform, which produced vomiting. It was then noticed that a fold of intestine floated over the tumour; it was therefore decided to puncture it. For this purpose an ordinary trocar and cannula were employed, and about twelve ounces of clear fluid were drawn off. With a probe passed through the cannula another cyst could be felt, and when punctured from the same opening a small quantity of fluid, not quite so clear as the first, was drawn off. The fluid, when examined after standing for three or four days, was found to contain some hooklets; these were seen in a field. On the 23rd, the size of the abdominal swelling having increased, a third cyst was punctured, and with an aspirator

fourteen ounces and a half of tolerably clear fluid were drawn off. On the 28th the patient left the hospital. The swelling was entirely gone, and the two sides of the abdomen were about equal. There was normal resonance where the swelling had been. Her general health was good.

**CASE 2. Contused Abdomen; Hemorrhage into Iliac Fossa; Cure.** (Notes by Mr. Gard.)—Emily C—, aged eight, was admitted into Lydia ward on January 2nd, 1882. On December 26th she was walking in the street when she came in contact with the handle of a barrow. The blow was said to have been across the abdomen. She was sick once or twice in the night and complained of great pain. Opening medicines were given and hot fomentations were applied. She seemed to derive benefit from this, but on January 1st she was very ill all day and was unable to stand upright. She consequently applied at the Hospital. On admission, seven days after the accident, there was great fullness in the right iliac fossa. The abdomen was not swollen. There was no pain on pressure of any part of the abdomen, and only a slight abrasion could be seen on the outer side of the right thigh. An ice-bag was applied and milk diet ordered. On January 11th there was still to be felt in the right inguinal region a swelling deeply placed and apparently in connexion with the deep tissues. This swelling was much larger and was considered by Mr. Bryant to be an effusion of blood into the abdominal cavity. There was now a little discolouration of the abdominal wall; no tenderness; no sign of fracture of ilium. On Jan. 12th there was very slight discolouration. The patient had been upon milk diet. No pain on pressure. The swelling in the right inguinal region could still be felt, but it had lessened. Six days later she was discharged convalescent.

**CASE 3. Ruptured Small Intestine, followed by slight Collapse; Death in twenty-five hours.**—Abraham C—, aged forty-five, was admitted on Dec. 3rd, 1881, into Accident ward. At 7.30 A.M. he was lifting a bag of cement weighing about two hundredweight to another man's back, when he slipped and fell about four feet, with the sack upon his abdomen. He was taken to the hospital in a cab. On admission his pulse was feeble, but he was not much collapsed; he felt sick, and laid with his legs slightly flexed upon his abdomen; his abdomen was tender on pressure; he passed water free from blood; his bowels were not opened. He was put on milk diet. At 5 A.M. the next morning his breathing became hurried, and he was almost pulseless. The dresser was called, and found him much collapsed and the body cold. His breathing became more difficult, his legs more flexed, and he died at 8.30 A.M., twenty-five hours after the accident.

**Necropsy, thirty-two hours after death.**—The lungs were gorged with blood; there was hypostatic pneumonia in both lungs, and post-mortem staining of the trachea and of the breast. The heart was normal. There was matting together of the intestines, chiefly in the left iliac fossa. Fourteen feet from the cæcum the bowel was ruptured for two inches, and a rupture of one layer of the mesentery over about two square inches, and ecchymosis beneath the mucous layer of the intestine at the same spot. The right kidney was small and fatty, and weighed  $3\frac{1}{2}$  oz.; the left was normal, and weighed  $4\frac{1}{2}$  oz.

### SHEFFIELD GENERAL INFIRMARY.

CASE OF ECTROPION SUCCESSFULLY TREATED BY TRANSPORTATION OF A LARGE NON-PEDICLED FLAP FROM THE ARM.

(Under the care of Mr. SIMEON SNELL.)

WALTER B—, aged twenty-one, first came under observation at the infirmary in the early part of November, 1881. He stated that eight years ago an abscess had formed on the right side of the face and orbit. For this he was treated at the infirmary; and a short time after another abscess formed underneath the eye; and still later others appeared on the forehead and upper eyelid. Six months subsequently Mr. Laver (house-surgeon) removed from the external and upper angle of the orbit a portion of bone about the size of a finger nail. The wound healed; but the right upper eyelid became fixed and drawn upwards, leaving the eyeball exposed. The patient attributed the abscess on the face to a blow from a cricket-ball he had received in that region. He further

stated that inflammation was constantly attacking the exposed eye, and latterly it had commenced to ulcerate.

The patient was decidedly a scrofulous subject, and on both sides his neck was marked by irritable-looking scars, resulting from suppurating glands. He had also family history of struma.

With respect to the ocular condition it was found that the right eyelid was completely drawn up, and fixed to the bony margin of the orbit at its outer part, exposing the palpebral mucous membrane, which was reddened and hypertrophied. No effort on the patient's part could in any way make the lid cover the globe, and as a result of this exposure well-marked ulcerations of the cornea at its outer part was present. Underneath the integument on the side of the face, and round the margin of the orbit, prominent spiculae and irregularities of bone were easily detected.

Before operation.

Operation for the relief of this deformity was not only desired by the patient for appearance' sake, but was rendered necessary by the peril the eye was in from its want of the protection afforded by the lid. Mr. Snell operated in the following manner:—On Nov. 21st, 1881, an incision was first carried through the integument between the margin of the upper eyelid and the edge of the orbit, and continued in such a manner that the lid fell easily into its normal place without dragging. The edges of the lids were now at two different points vivified and united by sutures to retain the upper one in its new position. The raw surface thus left on the surface of the lid measured one inch and a quarter in length and three-quarters of an inch in breadth. To fill this, after all bleeding had ceased, a large flap, measuring when mapped out two inches by one inch and a half, to allow for shrinking, was taken from the skin on the inner side of the left arm. This, after all the subcutaneous tissue had been carefully removed from its under surface and leaving only the integument, was found to easily fit the wound on the outer side of the upper eyelid. It was then secured by four or five fine sutures and covered with lint wrung out in warm water, over which gutta-percha tissue was placed. The dressings were allowed to remain undisturbed for forty-eight hours.

It will suffice to say that then the new piece of integument looked well and continued to appear so for the first six or seven days. It had become flattened down and its edges fastened to the margins of the wound, except at one point above, where there was a small spot of separation. At the end of the period mentioned, however, at the upper part it assumed a dusky appearance, and almost two-thirds or one-half of the flap sloughed. The remaining portion appeared quite healthy, and from it granulations spread out, but to prevent the possibility of the result of the operation being spoilt a minute dermic graft was placed between it and the upper margin of the wound.

It may be added that one of the points of adhesion between the lids gave way on removal of the sutures some days after the operation; the other portion firmly united,

and was allowed to remain for some considerable time during the cicatrization in the upper lid to counteract any tendency of the lid being again drawn up.

After operation.

The result in this case has been in every way satisfactory; and the lad was exhibited before the Sheffield Medico-Chirurgical Society on Feb. 23rd, 1882. He then possessed a good upper eyelid, and, not only was the appearance of the two eyes rendered alike, but it afforded a good protection to the globe, and the corneal ulceration has for some time healed.

Mr. Snell remarked that the operation here performed was that suggested by Lawson and Wolfe, and which has now been adopted by many operators. The method presented the manifest advantage that, if failure occurred, the patient was in no worse a condition than before the operation was undertaken, and opportunity could be still afforded of treating such a case by transplanting a pedicled flap from a neighbouring region. In the present instance, the patient was a most unfavourable subject for operation. Enough of the flap, however, lived to make an excellent cure; and in a more healthy man there is little doubt that the whole of it would have survived.

The engravings, from photographs, well show the condition "before," and some time "after," the operation.

## Medical Societies.

### OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

*Annual Meeting.—Election of Officers.—Miners' Nystagmus. — Homonymous Hemianopia with Paralysis of Centres for Upward and Downward Movements of the Eyes.—The Movements of the Eyelids in Association with the Movements of the Eyes.—Micrococci in the Interior of the Eyeball.—Tests of Vision best adapted for Service at Sea.—Acute Glaucoma caused by the use of Atropine and cured by Esérine.*

THE annual general meeting of this Society was held on the 7th inst., G. Critchett, Esq., Vice-President, in the chair. Mr. Streatfeild, the hon. treasurer, having read his report of the financial condition of the Society, the chairman delivered a brief address, in which he referred to the position of the Society, its proceedings during the past year, the share taken in them by the provincial Fellows, and the proposals to increase the facilities for the candidature of colonial practitioners. A resolution respecting the last-named subject was submitted to the meeting, and was unanimously approved. It was also resolved in future to

hold seven ordinary meetings annually, the last two to be held on "the first Thursday in June," and "the Friday following the first Thursday in July."

During the evening the ballot was taken, and the following gentlemen were elected to serve on the Council for the ensuing year:—President: William Bowman, F.R.S., LL.D., &c. Vice-Presidents: George Critchett; W. H. Broadbent, M.D.; C. E. Fitzgerald, M.D. (Dublin); Henry Power; Frederick Mason (Bath); Augustin Prichard (Clifton). Treasurer: J. F. Streatfeild. Secretaries: John Abercrombie, M.D.; E. Nettleship. Other members of Council: James E. Adams; Edwyn Andrew, M.D. (Shrewsbury); W. A. Brailey, M.D.; R. Brudenell Carter; W. R. Gowers, M.D.; R. Marcus Gunn; C. Higgins; George Lawson; Stephen Mackenzie, M.D.; Charles Macnamara; J. Vose Solomon (Birmingham); T. Shadford Walker (Liverpool).

Dr. OGLESBY of Leeds contributed a paper on "Miners' Nystagmus," in which he contended that this disease was due to organic cerebral changes which were at first temporary but finally became permanent; these changes were induced by venous engorgement consequent on the constrained position in which colliers were obliged to work. He endeavoured to support this theory by citing cases in which nystagmus was associated with epilepsy. He found that the movements remained in abeyance when the patient was erect and at rest, but returned at once on assuming the attitude of a miner at work. The attacks of epilepsy (petit mal) only came on, he believed, when the nystagmus had been in existence for some time. He did not think that errors of refraction had anything to do with the causation of the disease. In one case only had he found treatment by drugs do any good. In this case the nystagmus ceased after strychnine had been taken for six weeks.—Mr. NETTLESHIP said that from replies to queries he had addressed to practitioners in mining districts it appeared that nystagmus is almost confined to coal miners. Thus Dr. Hudson of Redruth writes that he never sees nystagmus among the Cornish miners except in those who have come from the coal mines in the north, and after a time they lose the affection. Dr. Evan Jones of Aberdare believes that miners' nystagmus is due to the combined influences of foul air, insufficient light, and straining of the sight in coal mining. Dr. Thomas of Swansea connects it with injuries to the head.—Dr. BRAILEY thought the evidence of central lesion was very slight, and attributed the nystagmus to weakening of ocular muscles from working in a constrained position and in a dim light. Nystagmus can be induced by looking constantly in one direction, and therefore it was a "fatigue" disorder.—Dr. S. MACKENZIE remarked that Dr. Hughlings Jackson believed nystagmus to be allied to writer's cramp.—Mr. SNELL of Sheffield had seen many cases of miners' nystagmus, and had never met with any evidence of organic disease. He coincided in the view expressed by Dr. Brailey, and pointed out that the coal miner has mostly to work lying on his side, so that he has for long periods to look obliquely, producing fatigue of the muscles. Internal remedies and galvanism do very little for the affection; but nearly all cases are curable by the man leaving off pit work, as Dr. Bell pointed out some years ago. He had never noticed any ophthalmoscopic appearances indicative of congestion. The best means of diagnosis was to get the individual to look downwards.—Dr. GOWERS pointed out that the same influences might excite nystagmus and epileptiform seizures without the same lesion being present in the two instances. It was difficult to draw the line between muscular fatigue and fatigue of the centre. If nystagmus be due to muscular fatigue, it was difficult to explain why it recurred on the patient assuming a certain posture.—Mr. MCHARDY had observed in some cases that the nystagmus was absent unless the patient looked above the horizontal line; so that many miners do not apply for relief until the condition is advanced. Dr. Priestley Smith devised a simple means of testing the degree of nystagmus by noting the different angles above the horizontal line at which the man could look without becoming giddy; and improvement was marked by increasing power to look above this line.—Mr. NETTLESHIP said that Mr. Oglesby in his paper states that nearly all the miners told him that they first noticed the symptoms when looking upwards.

Mr. LANG and Dr. W. A. FITZGERALD communicated a paper on a Case of Homonymous Hemianopia with Paralysis of Centres for Upward and Downward Movement of the Eyes; recovery, leaving Homonymous Insular Scotomata.

The patient was a man, aged forty-two, previously healthy, and presenting no signs of cardiac or renal disease, or of diabetes. When seen, three days after an attack of faintness and giddiness, without hemiplegia or loss of consciousness, there was total paralysis of upward and almost total of downward movement. No ptosis, but the lids did not move upwards when he endeavoured to look up, though they accompanied the slight downward movement of the eyes to a corresponding extent. Associated lateral movements, convergence, pupillary reaction, and accommodation normal; no diplopia. There was left homonymous hemianopia. A week later the movements of the eyes and lids had been partly restored, and the fields were normal, both for white and colours, except for the presence of insular negative defects at corresponding positions in each field, downwards and to the left. Four days later the movements were perfectly normal, and vision was with the right eye  $\frac{2}{3}$  and Jaeger 1, and with the left  $\frac{3}{4}$  and Jaeger 1. The condition has since remained unchanged in every respect.

Mr. LANG and Dr. W. A. FITZGERALD also communicated a paper on the Movements of the Eyelids in association with the Movements of the Eyes. They contested certain conclusions arrived at by Dr. Gowers, who believes that the movements are due to the fact that the lids are closely moulded to the globes, the edges of the upper and lower tarsal cartilages fitting into the "sclero-corneal sulcus." The authors endeavoured to show that this explanation is not correct, by pointing out that the movements still continue if the lower lid be withdrawn from contact with the globe, or if the eye be reduced to a mere stump. They described a fascia which connects the inferior tarsus with Tenon's capsule, and which explains the downward movement of the lower lid on looking down, and called attention to the close connexion between the upper and lower lids at the inner and outer canthus, the result of which is, that whatever depresses the lower must also depress the upper, and, conversely, whatever elevates the upper must also elevate the lower lid. The relaxation, or rather inhibition, of the levator, which is necessary in order to permit the descent of the upper lid, is, in Dr. Gowers' opinion, probably due to a reflex action set up by contraction of the inferior rectus, or by stretching of the fibres of the levator by the movement of the globe. This the authors endeavoured to disprove by quoting cases in which both upper lids descended normally on looking down, although the inferior rectus on one side was paralysed, and the globe motionless, and they suggested that the phenomenon was owing to the existence of associated centres for the movement of eyes and lids together.—Dr. GOWERS thought the authors weakened their case by affirming a universal negative to their assertion that it was impossible, under any circumstances, that the sclerotic and cornea can move the eyelids. The sclerotic bulges forwards the lower lid in looking upwards; and his explanation of this was that, besides the simple rotation of the eyeball on its own axis, there is an actual movement forwards of the globe. If this be so, it would be more easy to understand that the prominence of the sclerotic should move the lid. The authors' statement that the downward movement of the lower lid is effected through the connexion of the inferior rectus with Tenon's capsule did not accord with the fact that the movement of the lid takes place at the commencement of the rotation of the eyeball, when, on their theory, the movement should be at its minimum. The movement of the lower lid is a rotation on its attachments at the canthus. At any rate, he had not observed any movement of the canthi. If there were any real movement, it should be greatest at the latter part of the lid movement, instead of the early part. If, on the other hand, the movement of the lid be due to the pressure of the sclerotic, the increased degree of movement at the latter part of the period would be explained by the increasing resistance. In the cases he had described in his paper in the Medical and Chirurgical Transactions, there was no reason to believe the paralysis was central; one was a case of total paralysis of the third nerve trunk of one side. More observations were required. Similar objections as to the movement beginning at the canthus applied to the descent of the upper lid, and it was difficult to see how the slighter movement of the lower lid could influence the greater movement of the upper. In facial paralysis the movement of the lower lid may be very variably affected, the differences depending on the degree to which it falls away from the eyeball. In young persons, where there was more elasticity of tissues, the impairment of the lid was very slight, as com-

pared with old persons where there was loss of tone. When in paralysis of the orbicularis the eyelid is kept in apposition by its elasticity it moves with the eyeball.—Mr. COUPER said that Dr. Gowers' suggestion that there is a forward movement of the eyeball was new; he thought it was proved by Graefe that all its movements were round an axis. In support of this Mr. Couper mentioned the case of a persistent opacity in the hyaloid canal, where a spot of the string in the vitreous behind the lens could be seen to remain stationary in all movements of the globe, whereas the portions of the string in front of that point varied in position with the cornea.—Mr. HORROCKS had never found the fibrous expansion from Tenon's capsule described by the authors of the paper. If the upper eyelid be gently raised mechanically the lower lid is quite stationary; and if the lower lid be moved away from the eyeball there is not the slightest movement when the eye moves downwards. He asked whether the authors had seen cases of paralysis of the superior or inferior rectus only.—Mr. LANG, in reply, attributed the bulging of the lower lid to the fat in the lower part of the orbit coming forward in contact with the skin. The reason why the chief movement of the lid occurs at the beginning is because its area of movement is limited. Tenon's capsule is a layer of connective tissue separating the fat from the globe. If in the dead subject the lid be pulled away from the globe and, the orbit being opened from behind, traction be made on the inferior rectus, the lid makes a movement backwards. Again, if during life there be no globe in the orbit the movement takes place just the same. The case of paralysis of the superior rectus was under Mr. Nettleship's care; it was not seen by the authors of the paper.

A short paper, by Mr. JAS. F. RUDALL of Melbourne, upon Micrococci in the Interior of the Eyeball, was read by the hon. secretary. The eye had been destroyed as the result of a neglected gonorrhoeal ophthalmia, and was accordingly enucleated by the author. The cornea had ulcerated away; the lens was absent; and the iris adhered to the remains of the cornea by granulative material in which micrococci were found. Similar organisms were also found in the optic nerve; but it was doubtful whether they had not been accidentally introduced during preparation.

Dr. W. A. BRAILEY read a paper upon Tests of Vision best adapted for Service at Sea. After referring to the practical importance of defects in sailors in distinguishing form and colour, and the frequency with which such defects might be presumed to be present, the author stated that there was no test of sharpness of sight for form for either officers or sailors of the British mercantile marine; and that the examination for colour vision, which applied to officers only, was very imperfect. The Board of Trade, however, had made one step in advance when, about two years ago, it refused to admit to his first step as officer anyone failing to pass the colour examination. He thought the best course would be to create a superior class of sailors, who should occupy responsible positions as "look-out men" and helmsmen; such a class already existed in the French Navy. The tests recommended by the International Medical Congress were the best with slight modifications; he advocated the use of coloured spots viewed by reflected daylight, and coloured glasses of transmitted artificial light on the principle of Donders. Dr. Brailley concluded by describing a modification of Donders' lamp, which he found more convenient, and made some suggestions with regard to ships' lights.

Mr. SIMEON SNELL of Sheffield related a case of Acute Glaucoma caused by the use of atropine, and cured by eserine. The patient, a lady, aged thirty-five, consulted him on May 15th last. The right eye tension was +2, the vision equal to fingers, and the pain intense. The attack had commenced on the 13th, she having on the 9th consulted another surgeon elsewhere, who, in order to test her refraction (high degree of hypermetropia), had ordered strong atropine drops to be frequently applied until next day. Iridectomy was declined, and eserine was therefore employed in form of "discs," followed by almost immediate relief of pain, lessening the tension to normal, and in a short time restoration of perfect sight. The patient complained also of discomfort in the left eye, "coloured rings," and some increase of tension; eserine afforded relief to this eye also. The gentleman who first saw the patient asserts the absence then of any indication of glaucoma; on the other hand, the patient mentions symptoms which appear like the prodromata of the affection.

The following cases and specimens were shown to the

meeting:—By Mr. Nettleship: Case of Recovery from Multiple Growths in the Iris. One eyeball, which had been the seat of such growths, had been removed (see Ophthalmological Society's Transactions, p. 19). The growths on the remaining eye subsequently disappeared under iodide of potassium; but there was no evidence of syphilis. By Mr. M'Hardy: (1) Sequel to a case of Retinitis following injury to the head; (2) Spectroscopic Analysis of a Black Cataract. By Dr. S. Mackenzie: Microscopical Preparation of Retinal Hæmorrhages in Pernicious Anæmia. By Mr. H. Juler: Extensive Central Choroiditis in a Hypermetrope, aged twenty-two, with history of syphilis. By Dr. Brailey: (1) A peculiar form of Cyclitis, pigmented fibrinous exudation occupying a portion only of the internal (vitreous) aspect of the ciliary body; (2) Cyst-like Detachment of the pars ciliaris retinæ; (3) Colour Chart of Magnus and Joy Jeffries, consisting of nine rows of coloured discs, each row containing five shades of the colour.

### OBSTETRICAL SOCIETY OF LONDON.

A MEETING of this Society was held on July, 5th, 1882, Dr. Matthews Duncan, President, in the chair.

*Extra-uterine Gestation.*—Dr. DALY exhibited a specimen of tubal gestation, in which rupture of the cyst had taken place in the third month. The patient lived four days after the rupture. The nature of the case was diagnosed during life, and the question of opening the abdomen discussed, but decided against on account of the collapsed condition of the patient. Douglas's pouch was aspirated, and eight ounces of blood drawn off. On autopsy, about two pints of blood were found diffused in the abdomen, but no peritonitis. Dr. WILTSHIRE advocated prompt operative interference in cases of internal hæmorrhage from ruptured tubal gestation, or rupture of varicose veins in the broad ligament, especially where, as in this case, the diagnosis was reasonably clear. Mr. LAWSON TAIT agreed with Dr. Wiltshire. In case of doubt an exploratory incision would settle the diagnosis, was safe, and more satisfactory than tapping. Dr. ROUTH observed that a decidua was present. By dilatation of the cervix, the presence of such decidua might be ascertained and the diagnosis in a doubtful case settled. Dr. CARTER thought operative interference advisable in these cases. The specimen showed how easily the cyst might have been removed. Dr. CHAHBAZIAN (Paris) described the case of an actress who died in Paris from rupture of an extra-uterine gestation so suddenly that poisoning was suspected. In such a case no operation could have been performed.

*Removal of the Uterine Appendages.*—Mr. LAWSON TAIT showed fifteen specimens of Uterine Appendages removed by him since December, 1881, for hydro- or pyo-salpinx. The symptoms were pain aggravated by walking, by marital intercourse, and at the menstrual period. Five cases were due to gonorrhœa, and four either due to, or aggravated by, pessaries. In most the operation gave immediate and complete relief; in all there was improvement; none had died. He objected to the terms "spaying," "castration of women," "normal ovariectomy," because they implied that healthy ovaries were removed, an operation which he had never done. He thought the operation of doubtful value in neurasthenic cases; of these he had only done four, and at present was not disposed to go farther. For myoma its mortality was less than that of lithotomy in the male, and its results more certain. For the class of cases from which the specimens exhibited were taken, it was the only means which offered a hope of relief.

*Uterine Tumour.*—Dr. CARTER showed a Uterine Tumour weighing sixteen pounds and a half removed by him. The pedicle had been secured by Koberlé's serra-nœud.

*The Relation of Backward Displacements of the Uterus to Painful Menstruation.*—A paper on the above subject by Dr. HERMAN was read. It was admitted that there were cases of backward displacement of the uterus, accompanied with dysmenorrhœa, in which the menstrual pain was relieved when the uterus was elevated and straightened. The author found, from his own experience, and that of others, that such dysmenorrhœa was slightly commoner with retroflexion than with retroversion. The object of the paper was to inquire into the explanation of these facts. Three theories had been advanced to explain them. a. That the dysmenorrhœa was due to narrowing of the canal at the point of flexion, and consequent obstruction to the outflow of

menstrual blood. The author pointed out that there was anatomical evidence that the uterus might be bent to any extent without causing any hindrance to the escape of menstrual blood; that there was no anatomical evidence that flexion ever obstructed the canal, except when the uterus was fixed by adhesion, or its wall thinned by senile atrophy; and that this theory did not explain clinical facts. b. That the dysmenorrhœa was due to congestion from strangulation of vessels at the point of flexion. The author found no anatomical evidence that any such strangulation ever occurred; and said that the theory did not explain clinical facts. c. That the dysmenorrhœa was due to congestion produced by the pressure of the utero-sacral ligaments upon the veins running in the broad ligaments. The author found that the disposition of the parts concerned was such as to permit such pressure; that one case had been recorded in which there was anatomical proof that such pressure had actually occurred; that this theory was therefore supported by anatomical evidence; and that it explained clinical facts. The author's general conclusion was the following: "That while dysmenorrhœa accompanying retroflexion is often, it may be generally, dependent upon other concomitant conditions, yet that there are cases in which it is simply the result of the displacement, and that in such the dysmenorrhœa is probably entirely due, not to the flexion, but to the veins of the broad ligaments being compressed against the utero-sacral ligaments."—Dr. HEYWOOD SMITH thought that the symptoms accompanying retroflexion were generally due to other concomitant conditions, the flexion only in the minority of cases causing symptoms. The constriction at the point of flexion was apparent only, not real. In one case he had divided per rectum the utero-sacral ligaments; a low form of peritonitis followed, but the uterus had since remained in the normal position.—The PRESIDENT said that Dr. Herman had finally disposed of two great and unduly prevalent errors. The first was that in flexion of the uterus there was a projecting spur, or stricture, obstructing the passage of blood or fluid; the second was that behind the imaginary obstruction the uterine cavity was dilated. Much of the reasoning, both in this paper and in the one discussed at the last meeting turned on pain. Pain was too ill-defined a term to be wisely made the basis of conclusions; we had no good means of measuring its degree or kind, and nothing was more wanted. One woman would call excruciating what another would speak of as trivial. The utero-sacral ligaments could in many women be felt by the finger. Descent of the uterus so as to be grasped by the utero-sacral ligaments was a rare event. Ever since the paper of Dr. John Williams which had pointed out their action, he had attended to this matter clinically; but his observations had yielded him nothing of sufficient importance to lay before the Society.—Dr. HERMAN said it was impossible to avoid reasoning from pain; and he thought that errors due to the incorrect statements of a few individual patients became neutralised by taking a large number of cases. He did not think that the cases in which the utero-sacral ligaments caused congestion of the uterus were more than a small minority.

### Reviews and Notices of Books.

*Hospitals; their History, Construction, and Hygiene.* By J. F. SUTHERLAND, M.D. Edin. Edinburgh: E. and S. Livingstone: 1882.

THERE are so few English works which treat the question of hospital construction and management in a comprehensive manner, that every addition to the list is welcome, for there is no branch of practical medicine in which the profession as well as the public, stand in greater need of instruction.

The work of Dr. Sutherland is the graduation thesis of the year of his doctorate, to which a gold medal was awarded. Although it contains nothing new or original, does not deal exhaustively with any branch of the subject, and omits much that is necessary to its right understanding, it is a creditable performance. The author has collected and grouped with care and discrimination the leading facts and principles now accepted regarding the structural arrangements, ventilation, warming, lighting, and the other conditions to be observed in the location and building of hospitals,

as well as the proper means of dealing with the accessory agencies essential to their effective working; and has, in our opinion, correctly apprehended what the Germans have termed the "new view," in this all-important matter.

The most original portion of the work is that devoted to the Hertford Hospital in the immediate neighbourhood of Paris, of which Dr. Sutherland was, we believe, the first house-surgeon. It was built and endowed by Sir Richard Wallace for the sick and hurt of his own nationality in the metropolis of France. An accurate and detailed description of it appears in our issue of the 1st inst. It is a bijou institution, elegant in design and excellent in execution, and is said to contain "all that man could suggest, and money procure." This shows it to be unfitted for imitation and guidance in the construction of larger institutions of the same character, even were elaborate ornamentation and costly material essential—which they assuredly are not—to the successful treatment of disease, in buildings intended for the relief of sickness and its attendant dangers. The cost of the building is not given; it is reported to have been £40,000, which, if correct, would entitle it to rank, calculated on the number of beds it contains, with the new Hôtel Dieu and St. Thomas's Hospital in extravagant expenditure. In the present instance, however, there was full justification for the outlay, as it is designed to serve as a personal memorial, and is an undeniable proof of the splendid liberality of its founder. Having seen the hospital ourselves, and examined its arrangements, which are as perfect as a piece of marquetry in material and workmanship, we are by no means sure that it is as well adapted for its special uses as if it were more simple in design, and less artistic in execution. It must be placed in the same category with the elegant little hospital for scrofulous children built and maintained by the Rothschilds at Bercy-sur-Mer, as a magnificent testimony of the wise uses to which great wealth can be devoted; yet how far short do they fall of the benefits derivable from the grand and enduring work of the self-denying bookseller, Guy!

It is to be regretted that in so manageable an institution as the "Château Wallace," with a resident house-surgeon and two external superintendent medical officers, a perfect system of hospital record is not kept. In this it might, indeed, set an example deserving of imitation elsewhere, for it admits all classes of cases, and is even somewhat heroic and imprudent in opening its portals to dangerously communicable diseases, without the possession of proper means of isolation. Dr. Sutherland would not then have to lament as he does, that after analysing the statistics of two years, he could place little reliance in them, "as there were no two cases alike—the age, constitution, and habits of life, the season of the year, and other circumstances, exercising an influence upon the condition of the patient." So is it in all hospitals. It is for the unravelling and harmonising of these mysteries, and the deduction from them of the general laws by which the phenomena to which they relate are explained, that by the aid of the vital statistics of hospitals we can hope to derive the practical experience "which formulates the past, renders the present fruitful, and prepares the future." That a comprehensive, uniform, and general system of hospital statistics has still to be found, is a standing reproach to our profession.

The other hospitals described by Dr. Sutherland are all well known, and need no further mention.

*On the Treatment of Cancer.* By JOHN CLAY, Professor of Midwifery in Queen's College, and Obstetric Surgeon to the Queen's Hospital, Birmingham. London: J. and A. Churchill.

PROFESSOR CLAY publishes in a pamphlet form the articles which first appeared in this journal on the treatment of cancer, especially of the female generative organs, by Chian turpentine. Prefixed to the papers is an introduction,

dated April, 1882, which shows that up to this period Professor Clay's faith in Chian turpentine had suffered no abatement. The preface has one other feature of great interest—a statement that amongst other communications from numerous medical practitioners testifying to the value of Chian turpentine in cancer, is one from Professor Esmarch, informing Prof. Clay that "he has had a complete cure in a case of cancer of the bladder in a man." It would be interesting to know the particulars of this case, especially in respect of diagnosis, as also of "two cases reported," to Professor Clay, "of cancer of the liver cured" by turpentine. It is to be regretted that Professor Clay makes so little account of the small amount of confirmatory evidence adduced in support of his views, and of the serious adverse testimony, notably that of Mr. Hulke in THE LANCET of June 25th, 1881; and that of Mr. W. Brown in THE LANCET of Dec. 31st, 1881; the former showing that in the Middlesex Hospital the Chian turpentine was found to be thoroughly useless as a remedy; the latter that no signs of improvement occurred in eight cases treated in the Leeds Infirmary.

We shall not be suspected of any prejudice in this matter. We were only too glad to publish anything that seemed to justify a hope that a miserable and mortal disease was to be brought under the control of medicine. We did not by a word of doubt damp the ardour or the hope naturally excited by the papers of Professor Clay. But we only now feel the more free to say that it is time to take grave notice of opposing testimony, and to submit cases and cures to the observation of others. The subject is too serious, both in its human and its professional bearings, to admit of delay and discrepant testimony.

#### OUR LIBRARY TABLE.

*A Treatise on Aural Surgery.* By H. MACNAUGHTON JONES, M.D., Professor of Obstetrics and Gynecology in the Queen's College, Cork; Surgeon, Cork Ophthalmic and Aural Hospital, &c. Second Edition. Revised and Enlarged. London: J. & A. Churchill. 1881.—The early demand for a second edition of this work has justified the high opinion we had originally formed of its value. The new edition has been considerably enlarged and almost entirely rewritten, and is brought well up to date. Diseases of the ear are notoriously but imperfectly understood both by the profession and the public. Those who wish to study this class of affections cannot do better than take as a guide Dr. Jones' pages, which are based not only upon a good special knowledge, but on a wide acquaintance with general medicine and surgery.

*House Sanitation.* By G. H. STANGER, C.E. With Illustrations. Wolverhampton: John Steen and Co.—Mr. G. Hurst Stanger, Engineer to the Wolverhampton and District Sanitary Protection Association, has published a useful pamphlet on house sanitation. He describes in detail the various conditions of house drainage which are known to be associated with nuisance and injury to health, and he there explains how the several conditions may be remedied. The principles which he lays down are in no way novel, but they are put forward, by means of diagrams and otherwise, in a manner which can easily be understood. They are sound, and we can endorse them; indeed, if they were generally applied we should soon hear but little of diseases brought about as the result of sewer emanations getting into dwelling-houses.

*Holidays in Spain.* Being some account of two Tours in that Country in the Autumns of 1880 and 1881. By F. R. M'CLINTOCK. London: Edward Stanford. 1882.—This work appears very opportunely at the time when most of the busy workers who are in a position to take a holiday are beginning to consider where they can best dispose of themselves. The object of the author is to point out to those

who are tired of the everlasting round of Switzerland and other parts of the Continent, to which the English flock annually in such crowds as to destroy much of the enjoyment of travel, that there is a splendid field, hitherto comparatively neglected, within easy reach of England. Mr. McClintock describes in a pleasant manner a run in 1880 from London to Granada, visiting *en route* Madrid, Toledo, Cordova, and Seville; and in 1881 a revisit to Madrid by way of Barcelona, Tarragona, Valencia, and Saguntum. Travelling in Spain is an easy matter in these days of railroads; the hotels, as a rule, at least in the large towns, are comfortable, and the charges moderate; and the objects of interest are numerous. Although a knowledge of the Spanish language adds greatly to the enjoyment and to the instruction gained by travel in the country, it is not indispensable—at least in the more frequented routes. Circular tickets for the railways can now be procured, and are very convenient, but have the drawback of confining the holder to a predetermined route. In recommending our readers to explore this, to most of them, new field, we would merely give two cautions. They should invariably arrange beforehand the charges to be paid at hotels, taking care that there are to be no extras; and they should never forget to be courteous to all, whatever may be their rank or position. The Spaniard is, as a rule, polite, kind, and obliging; but he is also proud, and expects to be treated with courtesy. The last chapter of the book contains the result of the author's impressions of Spain, and a brief but interesting notice of its literature. The volume is one which may well be taken up as a pleasing amusement for a leisure hour, and as indicating in a general manner the variety of interesting objects to be seen during a holiday ramble through sunny Spain.

*John Howard's Winter Journey.* By WILLIAM A. GUY, M.B. Cantab., F.R.S., &c. London: De La Rue. 1882.—Under this modest title Dr. Guy gives us a charming sketch of the life and labours of the great philanthropist and reformer of our prisons. The volume comes opportunely at a time when the working of the present system is under discussion. There can be no doubt that we have made a great advance in prison discipline and management since the end of last century, but still there is much to be desired. Our present system is too inelastic and presses with undue severity, in some cases fatally, as repeated inquests have shown, on the weak and feeble, while, we fear, it has little deterrent effect on the hardy criminal. We have yet to learn how to discriminate in our punishments. One of the most interesting episodes in Howard's life, as narrated by Dr. Guy, is the description of the village of Cardington in Bedfordshire, which Howard converted from a damp, squalid spot to a village of wholesome-looking cottages, embowered in noble trees of his own planting. So excellent was the work, that the cottages "now, after a lapse of a century, seem as strong and sound as when they were first built; and having made a healthy, wholesome, and decent life a possibility to three generations, there is no reason why they should not continue to be a blessing to many more yet to come." Dr. Guy successfully, we think, rebuts the charge brought against Howard of harshness in his relations with his family. The medical evidence goes to prove that the insanity in the case of his son, which the detractors of the father endeavoured to show was the result of harsh treatment, was in reality due to the habits of dissipation into which he fell of himself, or was enticed, as some aver, by a servant of the elder Howard. Dr. Guy also advances another hypothesis to account for the son's insanity. The father was called an enthusiast; might not the enthusiasm of the father have developed into madness in the son? Howard's treatment of his child may not have been judicious, but there is no evidence to show that it was either harsh or cruel.

*Medical Adviser in Life Assurance.* By E. H. SIEVEKING, M.D., F.R.C.P. Second Edition. London: J. and A. Churchill. 1882.—The facts in this edition are pleasantly arranged, and a considerable amount of information is conveyed in a short space and in a practical manner. The style is graceful, and Dr. Sieveking, as becomes the Senior Censor and an advocate for the retention of the classical part of the examination for the membership of the Royal College of Physicians, aims his Latinity occasionally and always to the point.

## FORFARSHIRE MEDICAL ASSOCIATION.

DR. LAWRENCE presided at the annual meeting of this Society held at Brechin last week. The following office-bearers were elected for the ensuing year:—President: Dr. MacLagan-Wedderburn, Forfar. Vice-Presidents: Dr. Christie, Dundee; Mr. Murray, Forfar. Secretary: Dr. Sinclair, Dundee. Council: Drs. Anderson, Miller, McCosh, Rorie, and Messrs. C. Moon and Stevens, Dundee. Local Secretaries: Dr. Dewar, Arbroath; Dr. Lawrence, Montrose; Dr. Mackie, jun., Brechin; and Mr. Alexander, Forfar. A paper by Dr. Alex. Lawrence was read on "Salicin in the Treatment of Acute Rheumatism," and an interesting discussion took place. Dr. Miller reported that the committee appointed to consider the hygiene of infectious fevers were now in a position to report, and the following motion included their results:—That the Association recommends as follows: When an infectious fever has appeared in one or more members of a household, other members who may have been exposed to the chance of infection by intercourse with them, or otherwise, should not be removed to a household where there are others liable to be infected until the expiry of the period of incubation shows that they have escaped (without going to extremes, the period of incubation may, for practical purposes, be considered to be for small-pox, typhus, whooping-cough, and measles, fourteen days each, and for scarlet fever and diphtheria ten days each); that convalescents from these fevers should be considered as still liable to give off infection until the expiry of time, counting from the beginning of the illness, ranging from each fever as stated below: Small-pox, fourteen days after termination of scabbing; typhus, twenty-eight days from inception; scarlet fever, eight weeks from inception; diphtheria, six weeks from inception; whooping-cough, eight weeks from inception; and measles, six weeks from inception. Dr. S. Lawrence showed a case of spontaneous amputation of the foot in a child ten months old. A donation of three guineas was voted to the British Medical Benevolent Fund.

## BRIGHTON AND CANNES.

### To the Editor of THE LANCET.

SIR,—Mr. Robert Rawlinson, C.B., remarks in his letter that "you have written quite as strongly about Cannes as about Brighton, and apparently with less threatening results." As the author of nearly, if not all, the communications you have published relating to the sanitary condition of Cannes, I may supplement Mr. Rawlinson's observation with an item of information that may be of interest as an example in the present instance. The authorities of Cannes, far from resenting the frank relation of their difficulties and shortcomings, manifested their gratification at the interest displayed in their affairs. I have a letter from M. Hourlier, the architect of the town, expressing these feelings both on behalf of the mayor and himself. On the table of the Public Works Department of the Cannes Town Hall or Mairie is kept, for reference, all the numbers of THE LANCET containing articles on Cannes, and notably Mr. Rawlinson's letter on the Sewerage and Drainage of Cannes, published in your issue of February 11th. The latter exposure has the severest passages underlined. Yet foreigners are notably more susceptible to criticism than Englishmen, who for generations have been accustomed to freedom of the press and self-government.

I have the honour to remain, Sir,

July 18th, 1882.

YOUR CORRESPONDENT.

# THE LANCET.

LONDON: SATURDAY, JULY 22, 1882.

THE refusal of the Home Secretary to entertain the question of the appointment of a Royal Commission to consider the whole matter of hospitals, reminds us that this question still presses for solution, and that it cannot be much longer delayed without danger. Scarcely a day passes without piteous appeals to the public for aid towards the support of the unendowed asylums for the sick; the threatened collapse of one of the most important and useful of them (the Fever Hospital) for want of means; the living from hand to mouth and expenditure of their capital of many of them, with the growing feeling in the public mind that the institutions themselves are behind the age in construction and management, all point to the same conclusion. We can quite understand why, in the present state of the question, the State declines to interfere, because the facts and figures necessary for its right understanding have not been properly collected, and because many of the evils pointed out can and ought to be remedied without the intervention of authority, by the public and the profession, if there were a determined feeling and effort to grapple fairly with the whole matter.

The working of the Poor Laws since the passing of the Act of 1834, and the subsequent continuing legislation in the same direction, have provided amply for the needs of the actually indigent classes in sickness. But the very nature of those laws interferes injuriously in this matter with the poor who are sick, but who are not actually destitute, who decline to come upon the rates, and who are only left without resources by the occurrence of disease or accidents. Hence, and for other reasons of a similar kind, an official inquiry is imperative to determine in what exact direction further legislation is necessary, to meet an urgent public need. But, before such an inquiry can be efficaciously conducted, something more exact requires to be known of the general state of the hospitals, and their distribution and management throughout the country, than is now on record in a reliable form. It is abundantly evident that the information cannot be extracted from hospital managers, and that it can only be collected by a patient and exhaustive personal examination, carried out under the authority of the State, by persons armed with compulsory power to procure the information. For this reason we are disposed to think that an inquiry of the same character as that so well performed by Messrs. BRISTOWE and HOLMES nearly a quarter of a century since, is all that should at present be asked for; that a couple of competent officers should be selected for the work; that sufficient time should be allowed for its efficient performance; that it should be thoroughly exhaustive in its scope; and that it should extend to an investigation of the hospital system and institutions of other countries. It would be preferable to place it under the supervision and control of the Local Government Board, whose chief has a seat in the

Cabinet, and which possesses an efficient medical staff, by whom the information obtained could be collated and printed for submission to Parliament, for such action as may then appear to be necessary. It seems to us that this is the only proceeding likely to recommend itself to the authorities, as a reasonable means of dealing with the present dead-lock and difficulty, in the interests of all concerned.

Since the publication of the report of Messrs. BRISTOWE and HOLMES in 1862, an entirely new departure has been taken in hospital construction and arrangements. That report has long been out of print; its views were not generally accepted, and it is now little known; but it marked an epoch, and might be taken, together with the instructions issued by the Minister of the Interior in France in 1865 to all local authorities, detailing the hygienic conditions to be observed in the creation of hospitals, as the basis and starting-point of the new inquiry. The circular referred to gave effect to a report furnished by a special commission, presided over by General MORIN, with MM. BOUILLAUD, COMBES, DEVERGIE, GILBERT, HUSSON, LAVAL, DE LURIEN, MALGAIGNE (Secretary), MELIER, MICHEL LÉVY, PAR-CHAPPE, PAYEN, TARDIEU, and DE VATTEVILLE, as members. More competent and distinguished authorities could not have been found anywhere. Unless some such step as we have indicated be taken, and that quickly, it is more than probable that a large portion of our labouring population in town and country may be subjected to considerable distress and hardship during sickness, should the present hospital accommodation of the country fail in its appointed work, from any of the causes now in operation to paralyse its action, the chief of which is the manifest decline of public support.

THE electors to the Waynflete Professorship of Physiology, Magdalen College, have issued a notice to the effect that they will proceed to the election early in August, and that candidates must send in their names and any papers which they may wish to submit to the electors on or before the 20th of July.

The electors will not probably experience much difficulty in making their selection, for there are few, very few, who can be regarded as possessing the necessary qualifications. Yet upon their decision it depends in great measure whether Oxford is to become an important and numerously attended school for the fundamental subjects of medical education, or whether the office is to degenerate into a mere dilettante Professorship, held no doubt by a man of talent—for surely none other would dare to present himself,—who would now and again give to the world the results of some painstaking research, but who would be utterly unable to avail himself of the splendid opportunity that now presents itself of creating a school of physiology. The man whose services are now required must be young and energetic, familiar with physiology in all its bearings, willing to give up all his time to its pursuit, capable of delivering a course of lectures that shall be interesting and intelligible to a class of junior students, and at the same time able to guide, promote, correct, and supervise the work of the more advanced students and of those who exhibit special aptitude for this particular branch of study. He must be one who can by his own example tempt others into scientific research.

At a great university like Oxford there must always be some men of parts who with the possession of ample means and leisure need only to be brought into the magic circle to learn how charming is divine philosophy, and who require only an enthusiastic leader to be carried away by the passion for research.

The example of Cambridge should not be lost on Oxford. By selecting a man in the prime of life, of unusual ability, and possessed of singular powers of attracting good men around him by his earnestness and zeal, a physiological school has arisen within her walls second to none in Europe, and MICHAEL FOSTER may point with pride to the excellent work that has been accomplished in the laboratory over which he presides, and to the fact that many who were once students in it now occupy distinguished positions in other countries. So far as we can learn, Professor ARTHUR GAMGEE is the only candidate who is likely to come forward. It is probable that if he is disposed to leave Owens College, with which he has so long been connected, and at which he has done so much good work, he will not meet with any opposition. He is in every way well qualified for the post. He is at mid age, full of energy and enthusiasm; he has had large experience in teaching; he has done much original work; he is the author of the best treatise on physiological chemistry that we possess; and we much mistake if his large knowledge, genial disposition, and warm heart, do not make him a general favourite in the new society he will join at Oxford.

M. FRANCOIS FRANCK has communicated to the Bordeaux Medical Society some instructive results of the experimental obstruction to the pulmonary circulation. The effect of a hindrance to the circulation of blood through the lungs in causing engorgement of the right heart, and secondary insufficiency of the tricuspid orifice, is one of the most familiar facts in medicine. M. FRANCK'S object was to produce this experimentally in order to study more closely the physiological conditions and symptoms, one of which was the chief subject of the communication—viz., the indications of the pulmonary obstruction which are afforded by the jugular veins. The phenomena may be produced by the tracheal insufflation of irritant vapours, such as sulphurous acid, the animal having been rendered insensible by chloral or motionless by curara. This sets the whole contractile mechanism of the lung into energetic action, the muscular tissue of the bronchial tubes and of the vessels. Hence there is a retraction of the whole lung, indicated by the depression of the costal walls, and there is also a diminution of the calibre of the pulmonary vessels, causing an engorgement of the right side of the heart. If the obstruction lasts long enough and is sufficiently intense, the feeble parts of the wall of the right ventricle—i.e., the part above and to the right—yield to the excess of internal pressure, and drag outwards the papillary muscles, and the chordæ tendinæ, and with them the free edge of one of the segments of the tricuspid valve. By this mechanism, which was pointed out by KING in 1837, temporary tricuspid regurgitation occurs, and causes a venous reflux, visible as the jugular pulsation synchronous with the ventricular systole. The tricuspid insufficiency and venous pulse continue as long as does the engorgement

of the right side of the heart. This "safety-valve action," as KING called it, may be thus constantly produced artificially. The analogy between this induced condition, and that which occurs in every paroxysm of spasmodic asthma, is sufficiently close, and there can be no doubt that in the latter the same cardiac phenomena occur. It is probable that the production of this tricuspid reflux is facilitated by certain conditions of the heart itself. The diastolic relaxing influence of the pneumogastric nerve undoubtedly plays an important part in the experimental production of this condition, and no doubt also in its clinical production. M. POTAIN has insisted on the transient tricuspid regurgitation which seems to be produced by a nervous mechanism under the influence of strong irritation of the abdominal viscera, acute affections of the liver, intestine, and stomach. The reflex action may probably be double, and the effect produced not only by cardiac inhibition, but also by obstruction to the pulmonary circulation.

THE judicial functions of the General Medical Council have received some recognition, if not development, during the recent sitting of the Council. The Home Secretary's remark in Parliament, that the Council had power to deal with cases in which medical practitioners were making undue uses of unqualified assistants, gave great gravity to the position of the Council in the case of Mr. DAVID BEATSON MURDOCH, who was shown to have three different dispensaries, worked chiefly by unqualified persons. The facts of this case have been already commented on by us, and we may expect them to serve as a warning to those practitioners who place unqualified assistants in full charge, or what is virtually such, of dispensaries. The Medical Council have declared this conduct to be infamous in a professional respect; and it is scarcely to be doubted that if a similar case were to come before them again, they would use their power of erasing the name of the practitioner.

We propose to state the outline of several cases brought under the notice of the Council, as it is clear that henceforward the judicial function of this body, or of its successor, will not lie so dormant as hitherto. To be forewarned is to be forearmed. The Council, like the Corporations, has been so insensible to breaches of professional conduct that some members of the profession have become careless too. Juries and Parliament have the credit of raising public feeling on this question, and compelling the Medical Council to do its duty. Henceforth there will be no excuse for those who bring themselves under the punishment which the Council is empowered to inflict in the twenty-ninth clause of the Medical Act, which runs as follows:—"If any registered medical practitioner shall be convicted in England or Ireland of any felony or misdemeanour, or in Scotland of any crime or offence, or shall after due inquiry be judged by the General Council to have been guilty of infamous conduct in any professional respect, the General Council may, if they see fit, direct the Registrar to erase the name of such medical practitioner from the Register." In the Dentists Act the thirteenth clause gives similar powers to the Council as regards dentists, in respect of cases of felony or misdemeanour, or "any infamous or disgraceful conduct in a professional respect." The

following are some of the other cases in which the Council has had to act judicially during the recent sitting. The case of a registered dentist, Mr. VALLECK CARTWRIGHT MALLAN. Mr. MALLAN confessed to carrying on practice as a dentist in different houses, under various names,—at 173, Praed-street, and 64, High-street, Notting-hill, in his own name; at 94, Praed-street, as CHARLES SMITH; and at 106, Edgware-road, as C. VALLECK. The Council having received assurance that this practice shall be discontinued, did not think it necessary to take any further action. The Council was implored to restore to the Register the name of a practitioner erased in 1877 on conviction of an unnatural crime. The petitioner's argument was an appeal *ad misericordiam* on the ground that his health, mental and physical, had been broken by much worry and anxiety, and so that he had yielded to impulses altogether foreign to his thoughts when in health. The Council resolved to take counsel's opinion as to restoring the name to the Register. A very painful case came before the Council—that of WILLIAM STORY, of Linsdale, convicted of feloniously setting fire to a certain house in his possession with intent to injure and defraud. His name was ordered to be erased from the Register. It had previously been removed from the list of Fellows and Members of the College of Surgeons. The Council determined to leave another case for the present in the hands of the Branch Council, that of a practitioner found guilty of adultery with a patient in the absence of her husband. The Council also devolved on the Branch Council the duty of further investigating a charge against Mr. RICHARD ALBERT SHIPMAN PROSSER, M.R.C.S., L.S.A., brought by the King and Queen's College of Physicians, on behalf of one of their licentiates, Mr. EDWARD HYACINTH O'LEARY. At an inquest on the body of ELLEN ALLSLY Mr. PROSSER swore to having examined the kidneys and other organs and found them healthy, and that death was due to the negligence of Mr. O'LEARY. On this evidence Mr. O'LEARY was committed for manslaughter. At a second post-mortem the kidneys were found undisturbed. It was also found that the examination of the other viscera was most incomplete. The stipendiary magistrate thereupon discharged Mr. O'LEARY. The profession will look with interest to any elucidation of Mr. PROSSER'S conduct by the Council or the Branch Council. The Council was invited to proceed to an extensive erasure of names of persons in the Dentists' Register on the ground of their doubtful right to be there. But it did not accept the invitation. It gave power to the British Dental Association to prosecute Mr. T. L. CALLENDER, of Bridge House, Burton-on-Trent, for practising as a dentist there, not being qualified, and announcing himself as in practice with Mr. GODDING, M.R.C.S., Surgeon Dentist, though there is no Mr. GODDING in Burton-on-Trent.

JOHN COTTON, M.D. Edin., Inspector-General of Hospitals and Fleets, whose death took place on the 12th inst. at the Royal Naval Hospital, Stonehouse, Plymouth, served on board the *Arethusa* and *Royal Albert* during the Crimean war in 1854-55, was engaged in the batteries and trenches before Sebastopol, and for his services received several decorations. In 1857 he was present at the capture of Canton; also, on board the *Inflexible*, at the destruction of a piratical fleet and stronghold near Hong Kong.

## Annotations.

"Ne quid nimis."

### THE DEAD AT ALEXANDRIA.

ACCORDING to the advices received from Alexandria, this unfortunate city is in great danger of pestilence, on account of the large number of unburied bodies that lie amidst the ruins. We would urge, in the face of this statement, that should an epidemic arise from such a cause, the authorities would be greatly to blame. In this case, at least, it could not be said that the consequences were not foreseen. It was well known that the fleet would bring to bear the most powerful weapons that have ever been used since the invention of gunpowder. There could be, therefore, no doubt as to the havoc that would be wrought by such monster guns, if the Egyptians should prove bold enough to face the fire. Nor can it be urged that men and time were wanting to dig the graves. For such a purpose native labour could be obtained, if necessary by compulsion. If, in spite of these considerations, it should prove that it was impossible to dig graves of sufficient depth with the requisite promptitude, the sea offered another means of avoiding an epidemic. Our own sailors were buried at sea, and the sea has always been considered an honourable grave. There can be no lack of old boats or barges at Alexandria, that might have been filled with the victims of the bombardment and taken out some miles to sea, where a collective burial, with all the rites and ceremonies the Mahomedan population might desire, would have been performed, and several hundred bodies disposed of in a few hours. If time and labour were so scarce as not to admit of the lowering, one by one, of each body into the sea, then the boats and barges thus converted into huge coffins could be sunk at the conclusion of the funeral service. After all the destruction caused by the bombardment, the question of saving a few old boats is hardly worth considering; but no measure, however stringent, calculated to lessen the appalling danger of the outbreak at such a moment of an epidemic should be neglected.

### THE SEWERAGE OF THE WEST-END.

WE wonder whether the authorities of the West-end of London will bring an action against us if we dare to endorse an opinion expressed in a letter written to *The Times* by a competent surveyor, to the effect that the sewerage of certain districts of the metropolis is defective. Mr. Alex. Peebles, the district surveyor of the northern division of St. Marylebone, has done good service in calling attention to the deplorable and disgraceful state of the sewers in some of the most fashionable districts. He says:—

"A short time since, in consequence of a death from diphtheria, I was called upon to inspect the sanitary condition of a house in one of the fashionable West-end squares. After having carefully inspected the dwelling, I directed my attention to the streets in order to ascertain what provision existed for the escape of gases from the public drain, when to my astonishment I found that there was not a single ventilator in the whole square, except the gullies; and upon tracing this drain to its main sewer and following it, I found the ventilators so very far apart that their effect must be imperceptible upon the gases thus pent up. I have since made frequent similar observations with a like result. The effect of depending upon the gullies to act as ventilators also is that when a storm occurs—not an unusual thing—the rush of water into the sewers drives the gases rapidly through the private drains into the houses; indeed, they become the only exits, while at all times the private drain is sucking the sewer gas, unless the drains are effectively disconnected, which is seldom the case."

It is satisfactory to know that not only Brighton, but

London, will be benefited by the attention which our remarks and criticisms have directed to the mistaken policy of leaving the sewers to pour their foul and poisonous gases through open gratings into the streets. The mischievous effects of this wholly irrational system are more conspicuous in certain localities than they may be in others, but they are disastrous to health everywhere; and we have no hesitation in asserting that the total sickness and mortality of most populous districts would be sensibly reduced if the sewers were properly ventilated by shafts or pipes opening well above the level of the highest rooms in the adjacent houses, and no escape of gas were permitted on the street level. As we have repeatedly insisted, house-drains should be entirely cut off from the sewers, not by mere "traps," but by properly constructed disconnecting chambers. These are the imperative and urgent necessities of a sanitary condition at Brighton, and the same measures must sooner or later be adopted throughout the metropolis. The sanitary engineers know we are right, and they would consult the interests of public health if they spoke out boldly on the subject, instead of bolstering up a system which their own better judgment condemns.

### INDUCED FLUORESCENCE IN THE EYE.

EHRLICH has made the curious observation that fluorescence can readily be communicated to the liquids of the eye (aqueous humour), in which the phenomenon is very conspicuous on account of the dark background. In his experiments he employed uranin, the ammoniacal compound of fluorescein. Two cubic centimetres of a 20 per cent. solution were injected beneath the skin of a rabbit, and after a few minutes the aqueous humour was let out by paracentesis. After from a quarter to half a minute an intensely luminous green tint was visible at the edge of the pupil; in a short time the colour extended in the pupillary area, and in two or at most three minutes had filled the anterior chamber. This experiment shows that the anterior surface of the iris does not in any degree participate in the regeneration of the aqueous humour. According to Ulrich, a part of the transuded fluid comes from the vitreous (i.e., from the vessels of the choroid), and passes by the zonule of Zinn into the posterior chamber. Ehrlich's results are opposed to this assumption. If blood-serum is obtained at the same time, its tint is exactly the same as that of the transuded aqueous humour—a fact which makes it probable that the latter is a direct transudation from the blood. The rapidity with which the process goes on is also opposed to Ulrich's view, since within five minutes of the injection of the material the chamber is filled with the green liquid. In one animal, into which a considerable dose had been injected, Ehrlich observed the appearance of a pale-green line in the pupillary region, constantly vertical in direction, and corresponding in position to the greatest curvature of the cornea. A band developed out of this line, and this again into two stripes separated by a narrow dark zone. A short time after the line was distinctly visible, the cornea became separated into a medial and lateral dark zone, the division between the two being occupied by the green line. It is easy to demonstrate that the appearance of the line does not arise in the cornea, but in the liquid in the anterior chamber, immediately behind the cornea. The vertical direction of the line is no doubt determined by the shape of the eye. Ehrlich is of opinion that the line must be regarded as the result of the meeting of two currents of secreted liquid. At the periphery of the iris there are two centres of secretion: an anterior, nasal; and a posterior, temporal. When both currents meet, the peculiar hue is produced. The normal secretion of the posterior chamber is distinguished from the aqueous humour by its deep-green tint and a higher specific gravity. Under normal relations the secretion does not pass into the anterior cham-

ber; but abnormal influences, such as paracentesis, cause it to do so. Ehrlich believes, therefore, that his experiments have disproved the theory of Ulrich, that both chambers are connected by a filtration current, which passes forwards through the roots of the iris and the ciliary processes. Each part is probably supplied from the bloodvessels. The chamber is not supplied with liquid from the whole circumference of the iris, but from special centres. The short time in which the liquid can be reproduced is also an argument against the possibility of a filtration current. These experiments show that the fluorescence can be very readily produced, and may supply the means of elucidating many physiological problems. One advantage of the method is that, being absolutely devoid of danger, it can be employed on human subjects. The internal administration of fifteen cubic centimetres of the above-mentioned solution will suffice.

### PERILS OF THE HOT-AIR BATH.

THE hot-air bath, in all its varieties of construction and arrangement, is a powerful agent for the disturbance of the circulatory system. The change effected may be good, or it may be bad, for the subject; but it can scarcely be inoperative. The heart's action is quickened; the tension of the blood-pressure is at first heightened, and then—if copious perspiration take place—it may be reduced. Speaking generally, there is a determination of the blood to the surface, leaving the central and deep organs less fully supplied than before. In this way, doubtless, local congestions are occasionally relieved by the bath. Under ordinary circumstances, the change effected in the distribution of blood and pressure is likely to be beneficial, but if the heart be weak, or the larger vessels rigid, it may happen that faintness ensues. Then something is done, either by the affusion of cold water on the extremities, or in one or more of several empirical ways, to drive the blood in again, and this endeavour may prove the last strain that throws the whole physico-vital apparatus of the circulation out of working order, and renders the continuance of the essential functions of life difficult or even impossible. We believe the Turkish bath to be a most potent and, when rightly managed, useful agent for the control of the circulation; but it is necessary to warn the public against the reckless use made of it in cases the precise nature and peril of which are not understood. Except by the robust and thoroughly healthy, the hot-air bath should on no account be employed without express medical approval. Even this restriction is scarcely enough, because it may happen that the subject of a weak heart or abnormal bloodvessels regards himself as healthy, until the unaccustomed demand made on his organs of circulation by the bath discovers the weak place in his economy. It is not desirable to lay too much stress on those deaths which occasionally occur in, or after a visit to, Turkish baths. They are accidents in the use of the agency, and as such must be regarded as significant. At the same time, it is desirable that the dangers of the bath should be more generally understood than they would seem to be; and that the proprietors of these establishments should be required to instruct their managers and attendants to send at once for medical assistance whenever a visitor becomes faint or even momentarily unconscious. Such occurrences must needs portend peril of death; and, however large may be the proportion of instances in which the "slight faint feeling" or "sleepiness" passes away, it is manifest that a grave risk is in all cases incurred, and a responsible medical man should be instantly summoned to aid the recovery. There ought to be nothing left to the discretion of the manager or attendant in such a case. Again, although it is easy to see that proprietors would prefer to avoid deaths on their premises, no person who has

been ill or even slightly unwell in the bath should be allowed to leave the establishment without being seen by a doctor. Further, we think the practice of *sleeping* in the hot rooms ought to be interdicted. There is always danger at the moment of awakening.

#### DEATH FROM MORPHIA IN A HOSPITAL.

A DEATH under very distressing circumstances took place last week in Westminster Hospital. A man named Ebdon was an inmate in one of the wards suffering from severe heart disease, but sufficiently well to be able to sit up in the ward during the latter part of the day. In the same ward was another man, who was receiving hypodermic injections of morphia, which appear to have been given by the nurse in charge. One day, when about to give the customary injection, she placed the bottle containing the morphia solution on the table in the middle of the ward by which the man Ebdon was sitting. He then seized the bottle and drank off about a tablespoonful of the fluid. Every effort was made to remove the fluid from the stomach, and to counteract its poisonous effects, but they proved fruitless, and the man died from the effects of the morphia. Such an event is extremely distressing, more particularly as it tends to lessen the confidence of the public in hospitals. The coroner's jury returned a verdict of death by misadventure, but added a rider that in their opinion the nurse was to blame for leaving poisons within reach of patients able to leave their beds. Those familiar with the working of a hospital will hardly concur in this opinion, but they will rather ask how it is that the nurse was in possession of the bottle of morphia. The coroner's jury would have done better service if, instead of trying to affix blame upon a nurse who was not shown to have been careless, they had elicited whether it was the custom in the hospital for the administration of hypodermic injections of morphia to be relegated to nurses. We have no hesitation in saying that such a practice is to be deprecated in the strongest possible terms. It is no part of a nurse's duty to determine on the necessity for such an administration, still less on the amount required, and, least of all, is a nurse qualified to inject the fluid. Had the administration of hypodermic injections of morphia been kept in the hands of the resident staff we presume a bottle of a strong solution of morphia would not have been in the ward, and could not have been left on the table. The case clearly points to a danger connected with the other plan, and we hope it will prove a warning to the authorities of all hospitals, and that precautions will be taken to prevent the repetition of such an unfortunate accident.

#### NOTIFICATION OF DISEASE.

A VERY lively difference of opinion obtains between the medical officer of health of Nottingham, Dr. Edward Seaton, and a considerable section of the medical profession in reference to the expediency of a clause in the Nottingham Improvement Act, which requires the medical attendant in a case of infectious disease to give information to the householder of the existence of the infectious disease, the householder being required to notify the fact to the sanitary authority. Thirty-eight practitioners have presented a petition to the Town Council against the notification of diseases. At the request of the Health Committee, Dr. Seaton has drawn up a reply to the points of objection contained in the petition. The feeling of the petitioners seems to have been partly excited by the fact that the clause objected to was obtained somewhat indirectly in a Gas Bill. We share the feeling that questions like these should be raised boldly in the Legislature, and not carried by a side wind. On the main question we are of

opinion that the time has come when there should be a notification of disease to the sanitary authority. Very striking facts come constantly before us showing the urgency of this necessity. This notification should be the duty of the parent, or other responsible guardian, of the patient. In the Nottingham Act the medical man is only required to inform the householder or parent on whom the responsibility of notification rests. It is not a forcible objection to this requirement to say that the diagnosis of infectious disease is not always easy, at least at first. Clearly, the medical man cannot inform the parent until he is satisfied in his own mind of the fact. Neither do we see much force in this connexion in the comparison between the knowledge gained in the confessional and that of infectious disease. There is nothing discreditable or immoral in having infectious disease. Injury might accrue to the householder by publication of the fact; but there need be no publication of it, and the sanitary authority will greatly frustrate its object if it gives publicity to facts conveyed confidentially to it. The whole community is interested in the limitation of infectious disease, and public opinion should be educated to the point of regarding it as creditable in any citizen to place information of infection at the disposal of the public sanitary authority. This cannot be done without the assistance of the medical profession; but they should be relieved of the actual duty of notification.

#### SANITARY STATE OF MARYPORT.

MR. J. SPEAR'S report to the Local Government Board on a prevalence of typhus fever at Maryport discloses a history and a course of inaction in sanitary matters which are well-nigh incredible. A regular sequence of cases of what is now shown to have been typhus was in progress from April to July, 1881, if not for a longer period, and yet at the end of that time the epidemic is described by the medical officer of health as one which "from the mild typhoid form, assumed the form of typhus." The disease continued to progress, and at the date of the official inquiry, early this year, it was found that in this small town, containing some 8100 inhabitants, "considerably over 100, probably nearly 200, cases" had occurred. The prevalence of typhus is well known to be almost invariably associated with those special forms of filth which go hand-in-hand with overcrowding, whether of houses or of individuals, together with destitution; and from the description given by Mr. Spear it is evident that Maryport is a town exhibiting conditions which are typical of those referred to. The houses are almost everywhere built on quite insufficient area, narrow arched openings lead to crowded and squalid courts, and in some cases four streets form a square facing outwards, the enclosed quadrangular space containing courts and smaller squares huddled together. Many of the individual dwellings were found to be quite unfit for human habitation; their condition as to filthiness is described as really shocking: cellars wholly beneath the surface of the ground, and receiving their sole supply of light and ventilation from very similar cellars to the front, were used by several persons as sleeping apartments, and overcrowding was found to be of common occurrence. In 1866 an intelligent sanitary authority inserted a provision in a local Act forbidding lodgers to occupy any room that did not afford to each inmate a space equal to 400 cubic feet; but no attempt has been made to enforce this very desirable provision. Indeed Mr. Spear relates an instance in this connexion which we trust is exceptional even in Maryport. The inspector of nuisances reported that two cellar-rooms, which in point of size were only adapted to receive six persons, were overcrowded by reason of their containing more than double that number of inmates. The cellars were found to be unlawfully occupied as judged by the local Act; they were damp and dark; the only window

which could open in either of them was a pane of glass some eight inches square, and not a single requirement of Sec. 72 of the Public Health Act with respect to cellar tenements was observed; and yet in face of all this it is recorded that the medical officer of health "did not consider this overcrowding," and so the cellars remained inhabited. But quite apart from conditions favouring typhus, it appears that the ordinary work of abatement of nuisances and of the removal of conditions injurious to health had been almost totally in abeyance, and, even in the face of an infectious disease such as that which had prevailed, no disinfection had been carried out under the supervision either of the medical officer of health or of the inspector of nuisances, verbal directions alone having been given "in several cases." The sanitary authority has no hospital, and hence only the destitute were isolated under the direction of the guardians of the poor. But the hospital resorted to for this limited purpose turns out to be a flat over a rag and bone dealer's stores, the effluvia from which, it is said, penetrate into the wards above, whereas the sewage from the hospital is complained of as percolating the stores below. The sanitary story from Maryport seems almost without a redeeming point.

### THE CHEMISTRY OF PUTREFACTION.

THE Chemical Mechanism of Putrefaction, and the nature of the Alkaloids which result, is the subject of a recent communication to the Paris Académie des Sciences by MM. Gautier and Etard. They had previously shown that, as soon as the putrid fermentation of albuminous substances is well established, the reaction becomes alkaline, hydrogen disappears, and carbonic acid is released, at first rapidly afterwards more slowly, mixed with a little nitrogen and with traces of phosphuretted and sulphuretted hydrogen. At the same time, the liquids contain ammonia, with a little trimethylamine, fatty acids, lactic acid, a small amount of oxalic acid, traces of tyrosine, phenol, scatol, indol, guanidine, xanthine, and organic alkaloids. These substances are accompanied at the commencement by a mass of glucoproteins and a soluble proteoid substance, which disappears slowly. The authors of the paper believe that all this complex series of substances is due to the circumstance that the putrid fermentation breaks up the albuminoid molecule by a method of simple hydration, and reveals its complex constituents. The process really resembles the hydration of the albuminoids by baryta, which has been studied by Schützenberger, in which there is a similar liberation of ammonia and of carbonic acid, and of a like series of substances. Thus the albuminoid molecule is doubled under the influence of bacteria, just as under the influence of water aided by heat and alkalis; and it breaks up into two principal parts: one relatively resistant, from which the glucoproteins and later the leucines are derived; another unstable, forming ammonia and carbonic and other acids. It is supposed, therefore, that the odoriferous bodies observed during putrefaction, and also certain bases which may be obtained, must pre-exist in what is termed a "nuclear" form in the albuminoid molecule. To extract the basic substances the following method was found to answer best. The liquid products of putrefaction were acidulated with sulphuric acid and evaporated in vacuo, by which means the volatile acids, indol, phenol, &c., escaped. The residue was rendered alkaline by the addition of baryta, and then filtered and shaken up with chloroform, which dissolved the bases. They were extracted by fractional distillation of the chloroform and treated with tartaric acid. Potash added in excess to the tartaric solutions liberated a strong odour of carbylamine, and set free the oily bases, which could be separated by ether and dried in a vacuum. These resembled the bases described by Selmi: oily colourless liquids, bluing litmus, neutralising strong acids, and

giving with nitric and hydrochloric acids, ferrocyanide of potassium, and ferric salts, the reactions of ptomaines. They were precipitated by bromine, iodine, and the phosphomolybdates. They quickly became resinous.

### INFANTILE DIARRHŒA IN LEICESTER.

UNDER the influence of the recent unseasonably cold and wet weather the fatality of summer diarrhœa in our large towns was again very much below the average in the second week of July. It appears from the Registrar-General's last Weekly Return that during the week ending the 15th inst. the annual death-rate from diarrhœa among the eight and a half millions of persons estimated to be living in the twenty-eight largest English towns averaged 1.3 per 1000; it was equal to 1.4 in London, and averaged 1.3 in the twenty-seven provincial towns, which have an aggregate population very little larger than that of London. The main feature of these recent diarrhœa rates is the outbreak of the usual epidemic prevalence of the disease in Leicester. The annual death-rate from the disease last week in Leicester appears to have been equal to 7.4 per 1000, or nearly six times the mean rate in the twenty-eight towns. No deaths from diarrhœa were recorded last week either in Sunderland or Derby, whereas the death-rate from the disease ranged upwards in the other towns to 2.3 in Salford, 2.4 in Nottingham, and 2.7 in Preston. Thus the rate in Leicester was more than three times as high as that which prevailed in any of the other large towns. No fewer than 41 of the 63 deaths from all causes in Leicester last week were of infants under one year of age, against but 12, 13, and 22 in the three preceding weeks; and the fatal cases of diarrhœa, which had been but 2 and 4 in the two previous weeks, further rose to 18 last week. Ordinary July temperature would undoubtedly have caused a far greater excess of infant mortality than that recorded. It may be hoped that the local sanitary authority are fully alive to the necessity for exceptional measures for checking this waste of life, or at any rate for solving the yet unsolved problem involved in the question: Why does Leicester year after year suffer from this exceptionally high rate of infant mortality, mainly due to diarrhœa?

### LUNATICS.

IT is something to know from the delivery of Lord Carlingford on behalf of the Government, or, as he curiously designates the particular authority for which he speaks, the "Irish Government," that the desirability of "substituting the workhouse system for the more extravagant system of lunatic asylums" is recognised. It may now be hoped that not only the "Irish Government," whatever that may be, but the Government of the United Kingdom of Great Britain and Ireland will soon begin to look into this matter, and arrive at the same conclusion. Manifestly, there must come a time of awakening, when it will be seen that the policy of building vast asylums at great cost, and filling them with imbeciles, is not only ill-judged, but futile and ruinous. It is not merely on the score of expense that this feeling must be denounced, but because it diverts the most recent and best appliances for the treatment of insanity from their legitimate purpose, and postpones the day when lunatics will cease to be regarded as creatures to be put away—in comfort, perhaps, but without hope or intent to cure them—and when, for the first time in the history of this branch of so-called medical practice, they will be treated as the victims of a malady. Until asylums come to be constructed and managed as hospitals instead of refuges, we shall never know how much may really be done to arrest the progress and repair the ravages of mental disease.

## LONDON AMBULANCE SERVICE.

A MEETING of those interested in the establishment of an efficient system of ambulances in London was held last week at Charing-cross Hotel, presided over by Mr. James H. Crossman. The chairman gave an outline of the work of the committee that was appointed some months ago by the meeting presided over by H. R. H. the Duke of Cambridge. It appears that although the general hospitals sympathise with the movement they do not feel able to undertake to work the ambulances on account of the extra expense it would entail. We recently called pointed attention to the embarrassed condition of the finances of the general hospitals, which threatens to curtail their usefulness to a serious extent. We regret that from the same cause they are now prevented from taking up this new work, which would have considerably increased their efficiency. From its position and wealth we should have supposed that the authorities of St. Bartholomew's Hospital might come to a different decision. They could so easily undertake the ambulance work of the City, and their funds are able to bear the burden, and we believe that Sir Sydney Waterlow is personally interested in the ambulance scheme. In default of the hospitals the committee turned to the police-stations, and in this they were cordially aided by Sir E. Henderson. A thorough examination of the stations has been made, and the practicability of working the ambulance from them proved, and as a result fifteen police-stations have been selected at which to make a beginning. These stations are in as many different police divisions, and all of them are close to the four-mile radius from Charing-cross. It was proposed to have one horse ambulance at each of these stations always ready, and available for the use of anyone in the district. The ambulance designed by Dr. B. Howard, and known by his name, has been found to work well, and the committee has determined to adopt it for each of these fifteen stations. The scheme, as carried out at the London Hospital, is found to answer well, and with excellent practical results. In some of the larger provincial towns ambulance services have been organised, and good reports come in from them. Glasgow has a particularly perfect system, which is worked with the help of both telegraph and telephone. The meeting cordially adopted the report of the committee, and approved of all its suggestions. It has been calculated that £1000 is needed to start the plan, and the committee now appeals to the public for £2000 in order to put the matter on a thoroughly sound financial basis. There should be no difficulty whatever in quickly raising such a sum for an object so exceptionally good. We cannot but believe that when once well established and the working of the system thoroughly understood, these ambulances will be of immense advantage to the very numerous invalids who require removal from place to place, and that it will prove a very popular adjunct to our great hospital work.

## CHILDREN'S HOSPITALS.

WE have received a circular in regard to a proposed hospital for sick children in Paddington-green. The scheme would appear to be a legitimate extension of an institution which has already done good service—viz., the dispensary for children's diseases in Ball-street, Edgware-road. There is much to be said in support of the proposal. In spite of certain drawbacks it must be admitted that there is an unquestionable balance of benefit to the community in the establishment of children's hospitals. There appears to have been ample scope for those already existing in the metropolis, and no doubt the proposed institution would be a boon to Paddington. For our own part we look forward to the time, especially in regard to sick children of the poor, when dispensaries shall be provided with a complete and efficient system of trained out-patient nursing as well as proper medical

home supervision. But this, it may be said at present, is only a dream. Let us, at all events, frankly consider the responsibility of massing together sick children in a hospital unless every possible precaution has been taken for efficient ventilation and for proper quarantine, if not for complete treatment of intercurrent infectious diseases. With our present knowledge, opening a children's hospital is, indeed, no child's play. We confess we look with some anxiety on the starting of any children's hospital in a house, or couple of houses, and we believe this would be the feeling of those who are acquainted with the medical history, from beginning to end, of the Great Ormond-street and North-Eastern Children's Hospitals, and probably also of some of the others which were started in houses. We wish those who are promoting the Children's Hospital at Paddington all success in their admirable project, but if they can command enough pecuniary support to start with a new building which, however small, shall have the best known hygienic requirements, they will save themselves from much future anxiety, and obtain the confidence of the profession as well as the public.

## ARRESTED DEVELOPMENT.

AN extraordinary instance of "sporadic cretinism" was described by M. Ball at a recent meeting of the Académie de Médecine. The affection was not hereditary. The father was alive, sixty-two years of age, and intemperate; the mother was forty-two years old at the time of the birth of the patient. The members of their families were all intelligent and well-developed, but all the other children died at an early age from affections of the nervous system. The subject of the disease was the last child, and presented all the appearances of normal development at birth, and up to a year old, when convulsions occurred, and were repeated almost daily for more than three years, and his growth underwent an extraordinary retardation. At the present time he is thirty-one years of age, but only forty-three inches high, and his weight is only four stones and a half. The dentition has remained incomplete, nineteen teeth alone having appeared, all of which are now carious. The face is free from hair, which is abundant on the head. The latter is large but irregular, the forehead receding. The countenance resembles that of a fœtus preserved in a bottle. The sexual organs are well-developed. There is no trace of goitre. Intelligence is very imperfect. The patient is able to understand what is said to him, but has considerable difficulty in expression. He knows the letters of the alphabet, but cannot read. His disposition is said to be inoffensive, and his tastes those of a young child. The condition is attributed to defective feeding at the end of the first year of life.

## THE THIRD BLOOD-CORPUSCLE.

THE last published number of the Bulletin of the Royal Academy of Medicine of Rome contains a memoir by Professor Legge, entitled "Observations on the Blood of the Salamander, and of the Triton, concerning the plates (*piastre*) of Bizzozero, and the invisible Corpuscles of Norris." We give a literal translation of Professor Legge's conclusions on this important matter. "1. In the blood of tritons and salamanders, in addition to the white and the red corpuscles, exists a special morphological element, which, if not identical with, is at least analogous, to the blood plates (*placche di sangue*) of Bizzozero. 2. In the preparations of the same blood are to be seen colourless discs, which correspond to the description which Norris gives of his invisible corpuscles. 3. These discs are the result of an alteration which the red corpuscles undergo in the presence of water. This confirms what Bizzozero asserts concerning the absence of Norris's invisible blood-corpuscle in mammalia. 4. The alterations which red corpuscles undergo in the presence of water are

the solution and effusion of the hæmoglobin, the transformation of the nucleus, from the original oval, into a brilliant sphere, and the softening of the cellular membrane, which finishes by disappearing, leaving free the nuclei, which remain separate and floating in the liquid."

### BRITISH HOSPITAL FOR JERUSALEM.

WHILE other European nations have for years had their hospitals and dispensaries in Jerusalem, the English have been unable to take their part in such charitable work. The cause of this has not been any lack of interest or charity on the part of our countrymen, but only the obstruction of the "inexpressible Turk." For some years the Order of St. John of Jerusalem has been trying to obtain a site for a hospice, and at length this has been granted by the Sultan, and as soon as the necessary funds have been subscribed, a suitable building will be erected. An influential meeting for the promotion of this object was held at the Jerusalem Chamber, Westminster, on the 7th instant, under the presidency of the Earl of Shaftesbury. The Prince of Wales and the Duke of Connaught sent letters expressing their entire sympathy with the object of the meeting. It is intimated that £2500 will be required at once for the building and fittings, and an income of £400 a year to maintain it in efficient working. Suitable resolutions were passed at the meeting, and a small executive committee was appointed. As ophthalmic diseases are so rife in the Jerusalem population, it has been wisely decided to call the institution the British Hospice and Ophthalmic Dispensary. We trust that the committee will find no difficulty in raising the needed funds for such a worthy object.

### A NASTY RISK OF MEDICAL PRACTICE.

A PRACTITIONER of Galashiels has had to stand his trial before the High Court of Justiciary on a charge of rape, and with having taken advantage of an unmarried female who had submitted herself for a surgical operation. Medical men should always protect themselves from such charges by insisting on the presence of a third party. The charge in this case quite broke down; and after four hours and a half a formal verdict of "Not guilty" was returned, and the Crown resolved to abandon the prosecution. It is to be regretted that the Crown did not sooner find out the baselessness of the case against Mr. Edward Pratt Evatt. An address, signed by upwards of 1000 inhabitants of Galashiels, and expressive of esteem, was alluded to by the Dean of Faculty. We sincerely sympathise with Mr. Evatt, and congratulate him on the unanimous opinion of the Court and the esteem of the community in which he practises.

### THE MANAGEMENT OF LUNATIC ASYLUMS.

WE are not disposed to attach undue importance to the recommendations of coroners' juries with regard to the management of lunatic asylums, but it is impossible to avoid the feeling that a mistake of policy, if not a graver error still, is made when the Commissioners in Lunacy refuse to send an inspector to watch proceedings before a coroner in a case which is likely to end in a charge of murder. It is not considered beneath the dignity or inconsistent with the duty of the Board of Trade to watch the proceedings which arise in connexion with a railway accident: an inspector is appointed to assist the coroner, or at least to take official cognisance of the evidence given. It seems that the Commissioners in Lunacy are too high and mighty for any such concession to public feeling. We venture to think they greatly err in not meeting public opinion half-way. Unless some practical interest in the welfare of the insane is soon shown by the officials of Whitehall, it will astonish no

onlooker to find the Commission swept away as a costly encumbrance which has ceased to discharge the functions for which it was originally organised and has been hitherto maintained.

### THE MEDICAL STAFF FOR EGYPT.

WE are in a position to contradict a statement which has appeared in several of the papers to the effect that Surgeon-General Alexander Smith, at present in charge at Gibraltar, had been selected to proceed to Egypt as Principal Medical Officer of the troops which may be employed there. We have reason to believe that the administrative staff will consist of Deputy Surgeon-General Hanbury in charge of the Department, and Deputy Surgeon-General Ekin and Brigade-Surgeon Manley in charge of Divisions. Judged by their antecedents, the selection appears to be very judicious, and we have no doubt the responsible duties of the respective appointments will be efficiently and satisfactorily discharged. Eight field hospitals are in course of equipment and will be sent out as required, each being under the charge of a brigade-surgeon or a senior surgeon-major. The troops in Alexandria will be provided immediately with a complete hospital equipment and the necessary staff from home.

### THE CHAIR OF SURGERY IN EDINBURGH.

WE record with much satisfaction the fact that Dr. John Chiene has been appointed Professor of Surgery in the Edinburgh University, in succession to the lamented Professor Spence. The Curators had the embarrassment arising from having only one chair to fill and several suitable candidates. But we are sure that none of the unsuccessful candidates will deny that a very suitable selection has been made. Dr. Chiene is known most favourably not only as a pure surgeon, who practises his art with all the precautions of antisepticism, but equally well as a devoted teacher who finds his delight in expounding the principles of surgical science. He is a graduate too of the university, and has every inducement to labour in perpetuating its prosperity and its fame.

### A NEW TITLE, L.A.M.D.

IT transpired at an inquest on the body of Bertram John Askew, Caledonian-road, that Mr. Greatorex, who had attended the patient, gave a certificate that the deceased died of acute hydrocephalus, and appended to his name L.A.M.D. The parents thought Mr. Greatorex a qualified medical man. The Registrar, doubting Mr. Greatorex's qualification, made inquiry, and the L.A.M.D. admitted that he was unqualified. He explained that the letters meant Late Army Medical Department. Such conduct is simply a fraud on the public. As Dr. Thomas said, it is especially bad, because it misleads the poor. A post-mortem examination by Dr. Pepper showed the absence of acute hydrocephalus. It is satisfactory to know that the facts have been reported to the Registrar-General, and that Greatorex will be prosecuted.

### BROMPTON HOSPITAL.

DR. HERBERT ISAMBARD OWEN, M.R.C.P., St. George's Hospital, has been elected an Assistant Physician to the Hospital for Consumption and Diseases of the Chest, a vacancy in the medical staff having been caused by the resignation of Dr. William Ewart. Mr. Raymond D. Batten, M.R.C.S., St. Bartholomew's Hospital, has been appointed Resident Clinical Assistant in the room of Mr. Christopher Vise, whose period of residence has expired; and Mr. George V. Perez, L.S.A., University College Hospital, has been elected to succeed Mr. Arthur Foxwell, at the expiration of his term of office next month.

### THE REPORT OF THE ROYAL COMMISSION ON THE MEDICAL ACTS.

WE have already explained to our readers that only the Report of the Commission has been as yet published. The evidence on which the Report is based has yet to come. We understand it is not likely to be published before the early part of August. We must wait until this is received before we can form a just estimate of the labours of the Commissioners or of the testimony on which their important report is based.

### LIGATURE OF THE INNOMINATE.

MR. THOMSON furnishes us with the following particulars of the progress of his case of ligature of the innominate artery:—

"Violent hæmorrhage took place in my innominate case on the thirty-ninth day. It was controlled by shot-bags, and has not recurred since—that is, for sixty hours. There was an interval of nine days between the first and second bleedings, the patient on Sunday declaring that he had never felt better. He has now recovered somewhat, but I expect a fatal result. He has now survived forty-one days."

### A MEDICAL ACT AMENDMENT BILL.

A BILL is passing through Parliament, unopposed, to empower the new Royal University of Ireland to choose a representative in the General Medical Council, just as the dissolved Queen's University used to do.

WE regret to hear of the death of Dr. Alexander Silver, at the comparatively early age of forty-one. He was for many years one of the physicians to Charing-cross Hospital and was lecturer on physiology at that school. As a teacher and lecturer he was assiduous and painstaking, and his class will long remember his terse illustrations, his jocosity and ready wit. For some years past, however, his health had suffered considerably. On Thursday, July 13th, he was seized with vomiting, rapidly developing into uncontrollable hæmatemesis, which carried him off on Sunday last.

WE understand that a new volume of the Classified Catalogue of the Library of the Royal Institution of Great Britain, by Mr. Vincent, the librarian, is now ready. It includes the most important works published during the last twenty-five years, placed under their respective heads, accompanied by a synopsis and indexes of authors and subjects.

THERE is a wide-spread desire among the Fellows and members of the Royal College of Surgeons of England to make some complimentary recognition of Mr. Thomas Madden Stone's long and faithful services to the College. We shall be glad to learn that the scheme has taken practical shape, and that it is sure of the success it merits.

THE numerous friends of Professor Lund, of Owens College, will be gratified to learn of his steady progress towards recovery from an operation necessitated by a poisoned wound of the finger received some four years ago. The operation was performed in London by Mr. Lister.

IT is gratifying to find the name of Dr. Mackie in the list of persons who have survived the bombardment and massacre of which Alexandria has been the scene; his house, however, is stated by *The Times'* correspondent to be completely gutted.

AT the invitation of Dr. Edward Malins, the President, on behalf of the Council of the Midland Medical Society, Dr. Andrew Clark will deliver the inaugural address, before the Society at Birmingham, next session.

THE action brought by Dr. Abrath of Sunderland against the North-Eastern Railway Company for malicious prosecution, and which occupied three days in hearing at the Durham Assizes, resulted in a verdict for the defendants.

KING'S COLLEGE HOSPITAL is now closed both to in- and out-patients, and will remain so until the commencement of the winter session.

DR. A. B. GARROD and Dr. CRICHTON BROWNE have been elected Corresponding Fellows of the New York Academy of Medicine.

TYPHOID FEVER appears to be very prevalent in several of the principal cities and towns of South Australia.

## Pharmacology and Therapeutics.

### PULSATILLA.

ACCORDING to Clarus, the active principle of pulsatilla is anemonin, and Broniewski has lately investigated the action of this on frogs and rabbits, and also that of the extract, tincture, infusion, and decoction of pulsatilla. All the preparations were found to possess poisonous properties. In frogs the number of respirations and cardiac contractions was lessened, in ten or fifteen minutes if the dose was large, not until the end of a day if the dose was small. The animals were dead, and sat with head bent forward and half extended extremities, and could scarcely be excited to movement by sensory impressions. Cutaneous sensibility was preserved, and so also was the excitability of the motor nerves, but the muscular irritability was lowered. The heart continued to beat after the respiratory movements had ceased. Rabbits presented initial weakness and tremor of limb, and intense apnoea, which led to death after a paralysis of the extremities, commencing in the fore-limbs. After death intense hyperemia of the lungs was present, and signs of inflammation in the intestinal canal.

### RESORCIN IN DIPHTHERIA.

Andeer, who has employed resorcin in so many diseases, has recently used it in diphtheria, and states that, in the slighter forms of the disease, a single cauterisation with crystalline resorcin, or with a concentrated ointment of resorcin in vaseline, is sufficient to arrest the formation of false membrane; but in cases of greater severity repeated applications are necessary; while in the most severe forms of the disease he recommends that resorcin should be given internally as well as applied locally. We fear, however, that his recommendation of the drug must be received with some caution, since he makes the extraordinary statement that of 222 cases treated thus, not one died. If his diagnosis of the disease was correct in one-tenth of his cases, the result would still be satisfactory. He asserts that the agent appears to be a true specific, influencing the morbid blood state as well as the local process.

### SULPHUROUS ACID IN TUBERCULOSIS.

Some experiments by Froschaner on the treatment of septicaemia by sulphurous acid, suggested to Catani the trial of this agent in phthisis, and his experiments are of interest, not only from this practical aspect, but also in connexion with the discoveries of Koch. Phthisical patients were made to drink of water impregnated with it, and especially were made to breathe in closed rooms the air of which contained a considerable quantity. The experiments, continued for a considerable time, yielded the following conclusions: Most patients bear the long-continued inhalation of sulphurous acid remarkably well; only during the first few days, before

they have become accustomed to it, do they complain. All the cases thus treated became free from fever in the course of a few days, and subsequently remained so. As far as could be ascertained, the local mischief showed no tendency to increase during the treatment, and the amount of expectation became slighter. The observations are being continued in order to ascertain how far a permanent effect can be produced.

#### ARSENIC.

Two French observers, MM. Caillol de Poncy and Ch. Livon, have lately experimented on chronic arsenical poisoning. The effect of the addition of small quantities of arsenic to the diet of cats was not at first to cause any disturbance in the general health; indeed, they ate more, became fat, and seemed generally to be in exceedingly good health. After a time, however, they began to lose flesh, became affected with diarrhoea, lost appetite, and became languid, and finally died in a state of anæmia and emaciation, which presented a striking contrast to their condition at the commencement of the treatment. At the necropsy all the muscles, including the heart, were extremely pale; the liver, the lungs, and the kidneys presented all the naked-eye signs of fatty degeneration, and the mesenteric glands were swollen, and also presented fatty degeneration, a lesion which has not previously been observed. In the lungs Cornil and Brault found, in acute poisoning, that the pulmonary capillaries were dilated and distended with blood, and the endothelial layers were invaded with large fatty granulations. Hemorrhages were also seen in certain points, and many alveoli were filled by degenerated cells, giving rise to the naked-eye appearance of pale islets. The mesenteric glands appeared as large yellowish-white masses of caseous aspect. The microscope showed that the peripheral part of the glands was invaded by fatty degeneration, which was not limited to the follicles. The process of change appears similar to that in the lung: under the influence of the slowly absorbed arsenic the endothelial cells undergo fatty degeneration, commencing in the most active part of the glands—the follicular region,—from which it gradually invades the greater part, if not the whole, of the gland.

#### NITRATE OF SILVER.

In some experiments on chronic poisoning by nitrate of silver Roszhegzi says that a dilute solution injected into the stomach causes rabbits rapidly to lose flesh; but the functions of respiration and the action of the heart are not disturbed until shortly before death. The pathological appearances found were redness of the mucous membrane of the pharynx and larynx, congestion and even hepatisation of the lungs, with a cell growth in the walls of the alveoli. In the cases of longest duration he found the liver shrunken, its connective tissue increased, and the cells in a state of fatty degeneration. The connective tissue of the kidney was also increased, and the epithelium degenerated. The striated muscles were also granular. Small doses raise the temperature a fraction of a degree, whereas large doses lower it. If nitrate of silver is injected under the skin it seems to be eliminated by both the intestine and the kidneys, but more speedily by the former than by the latter.

#### PHOSPHORUS.

Danillo, in phosphorus poisoning, has found inflammatory changes in the spinal cord, either a central or a diffuse myelitis. In acute cases the central nervous system contains accumulations of pigment proceeding from effused blood, and recent effusions may be traced in the central region throughout the entire length of the spinal cord. Small, often-repeated doses cause a very interesting diffuse inflammation of the cord. By varying the dose, both forms of inflammation may be produced, and to these changes most of the nervous symptoms observed during life may be referred.

#### CHINOLIN.

The physiological action of chinolin has been investigated afresh by Bach and Loimann. They made it synthetically by the method of Straus, by heating nitro-benzol, anilin, and glycerine in the presence of sulphuric acid. The sulphuric acid withdraws the water from the products of decomposition of the three former, and leaves chinolin. A tenth of a gramme produced in rabbits a fall of temperature amounting to  $3^{\circ}$  to  $1.1^{\circ}$  C. within an hour; the fall was followed by a subsequent rise, which in many cases exceeded the original temperature. Larger doses,  $3$  to  $5$  gramme,

caused a very considerable and permanent fall in temperature, usually ending in death. The respirations were irregular and superficial, and increased in number after small doses;  $2$  to  $3$  gramme rendered the animal helpless and dull, with a diminution in the reflex excitability, and  $6$  to  $1.0$  gramme caused complete paralysis, with loss of all reflex action, and death in collapse. A cumulative action was not observed. Hyperæmia and œdema of the lungs were found after death.

### THE EXHIBITION OF APPLIANCES FOR THE PROTECTION OF HUMAN LIFE.

POWERFUL patronage and a most worthy purpose have not sufficed to make this Exhibition a success. Exceptionally unfavourable weather, feeble publicity, and defects of management have all combined to reduce the number of visitors, and to occasion much dissatisfaction among the exhibitors. During the present uncertain weather, a journey to the Alexandra Palace is not particularly inviting, nor is it encouraging to find, on reaching the Exhibition, that some of the owners of the most interesting exhibits have not yet got their stalls in order or their goods in place. English sanitary appliances are very poorly represented; but this is only natural considering how recently displays of this description have been held at South Kensington and at Brighton. A novel feature was, however, promised by the advent of upwards of thirty German patentees whose inventions were to have formed part of the great sanitary exhibition at Berlin which was destroyed by fire. Unfortunately it is precisely the Germans who have in many instances failed to make good their appearance. Some of their apparatus are still in the docks, and it is doubtful if they will reach the Alexandra Palace before the Exhibition is closed. The German exhibit actually in working order, and which most readily attracts the visitor, is that of Messrs. A. Schörke and Co.'s pea sausage combined with bacon and ham. This improvement on the celebrated sausage the German soldiers used during the Franco-Prussian war weighs 18 oz., yields eight pints of thick soup, and costs only sixpence. The pea meal of which it is made contains 18.44 per cent. of albuminous substances, and the lentil meal 21.50 per cent. With such cheap and highly nutritious food at hand no one need starve. Herr Johann Scholz of Laubegast, Dresden, exhibits, together with their analysis, highly nutritive biscuits, cocoa, and chocolate made with pea, bean, and lentil flour. If such articles were in more general use they would save many poor people from the fatal consequences of insufficient food. As the Germans are renowned for their power of living on the smallest conceivable incomes, it is not surprising that they should excel in the manufacture of cheap food.

The purely sanitary appliances at the Exhibition are anything but novel. Smeaton's closets, the antiseptic closet, and Boyle's ventilating cowls hold prominent positions, but show nothing new. By the side of Lloyd's improved ventilating cowl will be found a very ingenious joint for ventilating shafts in wrought metal, which would render the displacing or leakage of the joints impossible. An outer ring or belt about four inches broad forms a socket, into which the upper portion of the pipe is inserted and soldered.

Mr. R. Adams' patent window frames and apparatus for opening fanlights are particularly useful in assisting ventilation and preventing accidents. The upper and lower part of the window can be opened and shut in the ordinary manner, or it may be opened as a louvre window; and finally, revolving on a central pivot, both portions can be brought down to the level of the window-sill, and being spread out at right angles, every corner can be reached by the servant standing on the floor of the room and polished in the same manner and with the same facility and action as the surface of a table. Further, this window is so contrived that even when partially opened it cannot be further opened from the outside, so that ground-floor rooms may be ventilated without the fear of thieves gaining access. Nor is this great improvement expensive.

In respect to ventilation, the few exhibits in this section relate rather to ships than to houses, and we failed to find

anyone present capable of giving the necessary explanation. Capt. F. L. Norton's system of ventilation by two huge bells that rise and fall in two drums is really a means of artificial breathing. The drums communicate to all portions of the ship by various pipes, the one drawing up the foul air, the other pressing forward the pure air, as the bells within the drums or cylinders rise and fall through the action of cross-beams worked by an engine. So long as the engine does not get out of order and sufficient power is used, this invention renders the greatest service, particularly if care be taken, in pumping the air in, to diffuse it, so as to avoid draughts.

The most important sections of the Exhibition are those that relate to the prevention of railway accidents and to the saving of life at sea. When we consider that about 9000 persons are killed and injured on our railways every year; that about 3000 persons are drowned during the same period of time in our docks, rivers, and inland waters; that last year the Life-boat Institution saved 1121 lives from various wrecks—the interest and importance of this subject will be readily admitted. We cannot, however, profess to criticise the various proposed improvements in the systems of brakes, signalling, &c., nor have we much to say concerning the life-buoys, floating costumes, &c., provided for sea journeys.

Another section, relating to the work in mines, is also very interesting. There are 484,933 persons engaged in mining in this country, and it is calculated that 1 in every 500 is killed, and 1 in every 368 seriously injured. In this respect the Germans have some very good safety-lamps, notably G. L. Brichmann's patent; while among the English exhibitors, the Purdy pneumatic lock lamp seemed to us a clever contrivance.

There are various ambulance vans for public and private purposes, and the well-known exhibits of the St. John Ambulance. Many of the ambulances for civil use were so formidable in appearance, and their purpose so unmistakable, that their repeated presence in any one quarter during a season of epidemic could not fail to attract notice and occasion panic.

Among the miscellaneous exhibits we were glad to notice that of the Surgical Appliance Society for the Relief of the Crippled Poor. Here is shown the Beaufort artificial arm and leg, which are already so well known for their lightness and cheapness. Various diving and noxious gas apparatus are of great use, and particularly that of Messrs. Fleuss, Duff, and Co., which has been tried after colliery explosions and in the Severn tunnel. W. Bowden's automatic chariot for infants, in which they can stand, walk, sit, and have a table before them to play upon, is convenient and safe, and has been usefully employed for children with weak limbs. The same exhibitor has some excellent toys imported from India that cannot poison the children who put them in their mouths, and some potash soap for hard waters. Close at hand, however, will be found the formidable display of Jeyes' perfect purifying soap, and his di-infecting fluid, now well known and thoroughly appreciated. The exhibits of the Silicate Paint Company, Messrs. J. B. Orr and Co., have already been described in these columns, when reviewing the sanitary appliances at South Kensington, and we are glad to note that no effort is spared in making known to the public these most effective substitutes for the poisonous lead paints that should no longer be used.

In conclusion, we should mention that of all the exhibits, the most likely to create interest is the steel and iron compound, patented by Mr. Leighs, which has the extraordinary property of breaking up and taking the centre out of a rifle bullet. This substance is not so heavy as the armour worn by the ancients, and yet it will resist the bullet of an Enfield rifle; and for 3s. 6d. a metallic cloak can be provided to the marksmen at the rifle butts, which will save them from all danger, even if hit by the bullets. For ambulance purposes this material is invaluable, for it will now be possible to bring ambulance waggons out under heavy fire. Shields of this metal have been ordered to protect the sailors on the decks of Her Majesty's ships; while the German Government has purchased a large number of screens, which soldiers will carry in front of them and use instead of digging trenches. Should this invention prove as successful in actual warfare as the experiments that have been made would lead us to infer, there is some prospect of returning to the armour and the hand-to-hand fighting of the olden days. In any case, we shall be grateful for any portable means of protecting the medical staff and their patients from the stray bullets they so frequently encounter when in action.

## WILLS AND BEQUESTS.

THE will of Joseph Salkeld Johnston, M.D., Surgeon-Major, retired, Army Medical Department, of Seal Chart, near Sevenoaks, who died on May 30th last, at Lynwood, near Penrith, was proved on the 27th ult. by Mr. Thomas Johnston, the brother, the sole executor, the value of the personal estate exceeding £24,000. Subject to an annuity of £50 to Ida Hammond, the testator leaves all his real and personal estate to his said brother.

The will of William Millett Boase, M.D., of Plymouth, who died on May 4th last, was proved on the 23rd ult. by Mr. George Clement Boase, the son, and Mr. Alfred Boase, the executors, the value of the personal estate exceeding £500. The testator disposes of his freehold house property and his personal estate in favour of his wife, his said son, and his daughter, Mrs. Edith Anna Belcher; his daughters, Mrs. Ellen Bradley and Mrs. Mary Millett, having been already provided for by appointment.

The following legacies have recently been left to hospitals and other medical charities:—Mr. George Cheesman of Neckinger-road, Bermondsey, and of Holden House, Dorking, £50 each to the Royal Sea-bathing Infirmary, Margate, and the National Hospital for the Paralysed and Epileptic, Queen-square, Bloomsbury.—Mr. Arthur Wells of Nottingham, solicitor, £500 each to the Nottingham General Hospital and the Nottingham Dispensary, and £2000 to the Edinburgh Medical Missionary Society.—Miss Margaret Trotter of 9A, Upper Brook-street, and of the Chateau la Rocheville, Pecq, near Versailles, £3300 Midland Railway stock to the London Homœopathic Hospital, and her property, La Rocheville, to the Civil Hospital of Saint Germain-en-Laye.—Miss Anne Arundell of Carlton-crescent, Southampton, £100 each to the South Hants Infirmary and the Southampton Dispensary.—Mr. Samuel Gurney of 20, Hanover terrace, Regent's-park, on the death of his wife, £50 each to the Hospital for Diseases of the Skin, Stamford-street, Blackfriars, the Poplar Hospital, and the Nursing Sisters' Institution, Devonshire-square.—Mr. Lewis Lazarus of 29, Great St. Helen's, and 38, Tavistock-square, £20 to the London Hospital, Whitechapel.

## MEETING OF MEDICAL OFFICERS OF HEALTH.

A COMBINED meeting of the members of the North-Western and Yorkshire Associations of Medical Officers of Health was held at Doncaster on Friday, June 30th, Mr. S. W. North, President of the Yorkshire Association, in the chair.

Mr. B. S. BRUNDELL, M.Inst.C.E. (Doncaster), read a paper on Sewer Ventilation. The great need for ventilation arose from the present defective conditions of town sewers owing to their not being constructed with sufficient self-cleaning falls. The ordinary methods, by manhole openings, by untrapped gully grates, or by pipes up the chimneys of houses, were not free from risk to the neighbouring householders. He urged that sewers should be systematically flushed, and the outfall of main sewers should be provided with falling doors to prevent wind blowing up the sewers.

Mr. MASTERS, Architect (Doncaster), read a paper on the Circulation of Air in Sewers, which he believed was generally very defective from the insufficient fall, and consequently the very slow rate at which sewage travelled through the sewers allowing of the formation of offensive gases.

Mr. J. M. FOX, Medical Officer of Health (Midcheshire), then read an able paper on Scarlet Fever in connexion with Defective Relations between the Dwelling and the Sewer. He stated that, guided by the germ theory of disease, we were constantly reminded that it was with the conditions of life itself, and not mere chemical reactions, that our sanitary investigations were concerned, and that the greatest safety against zymotic impact consisted in the removal of those conditions of putrefaction amid which these forms of life flourish. There had recently been a tendency to divorce scarlatina, as far as sanitary regulations were concerned, from some other kinds of zymotic diseases, as far as sanitary regulations were concerned; also too much attention was given to the

infection lying in the particles shed from the skin, or upon the exudations from the throat. Mr. Fox considered this concentration of energy was wrong, for two reasons: First, he considered a fortnight after the cessation of the fever the epithelium then shed after the disinfection of the skin was harmless; and, secondly, that it was a mistake to look to this as the only source, or even the principal one, which could be the most active means of communicating the disease. He had arrived at the conclusion that the germs of scarlet fever in various excretions and in the washings of infected bedding and clothing might obtain direct access to the air, to the sewers, or to drains or ashpits, wherever their domestic drains or arrangements for disposing of house refuse were not under efficient sanitary control, and to these might be traced outbreaks of scarlet fever. He would therefore consider that sufficient attention was given to isolation and the thorough disinfection of all secretions before they were consigned to the ashpit or the sewer, both during the fever and for a fortnight afterwards. He also believed that the withdrawal of sewer air from houses and the removal of filth before any retrocedent changes took place had as direct and important a bearing upon liability to outbreaks of scarlet fever as to those of other diseases more exclusively identified with poisonous changes in excreta.

Dr. J. MITCHELL WILSON, Medical Officer of Health (Doncaster), also read a paper on the Ventilation of House Drains. He affirmed that houses ought to be more effectually cut off from waves of sewer air passing along the house drains than any water-trap could possibly do. After explaining the defects usually found in the connexions of house drains and their influence in causing outbreaks of disease, the model by-laws of the Local Government Board relating to the ventilation of house drains were discussed. A hearty approval was given to the suggestions, whereby at least two openings are required at the opposite extremities of all house drains, thereby ensuring not only an outlet for foul air, but also a constant current of fresh air through the drains.

A very interesting discussion took place on the reading of the papers.

### LOCAL GOVERNMENT DEPARTMENT.

#### DR. BLAXALL'S REPORT ON NORTH AND SOUTH TAWTON.

North and South Tawton lie within the district for which the guardians of the Okehampton Union act as rural sanitary authority. North Tawton has a population of about 1868; and there were found in it by Dr. Blaxall conditions, both general and local, which were, in a flagrant degree, prejudicial to health and specially favourable to the spread of such a disease as enteric fever. These conditions included badly constructed and ill-ventilated drains and sewers, unwholesome closets and privies, and polluted wells. The precise connexion of enteric fever with some of these conditions was clearly made out. One outbreak was occasioned by the use of water from a well which had become poisoned by the specific evacuations of an enteric fever patient, whose soiled linen had been washed in a sink under the pump, whence soakage into the well took place; and the fact affords another proof of the imperative necessity which exists for dealing separately and guardedly, whether in a laundry or elsewhere, with all linen from infectious patients. Another

condition favouring the spread of infection was found in the circumstance that the water-mains were in direct communication with the waterclosets in such a way as to facilitate the suction of foul air, and even of excremental matters, into the water-pipes. We fear that, notwithstanding numerous warnings, this highly injurious system of supplying waterclosets direct from the main, and without the intervention of a cistern, is far more common than is supposed. South Tawton lies in an open position on Dartmoor, and, although swept by fresh breezes, and having near at home an abundant supply of excellent water, it has been subject to prevalences of the same disease, and this notwithstanding the fact that its numerous excremental nuisances, which afford such peculiar facilities for the spread of the infection, have been pointed out by the former and the present medical officers of health, Dr. Blyth and Dr. Ash. A properly constructed privy to each house, together with some surface channel for drainage, seem to be the principal needs. There ought to be no difficulty in securing their provision.

#### REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Belfast.*—During the five weeks ending June 24th the births registered amounted to 709, and the deaths to 449. The average death-rate from all diseases was 22·4; from lung affections 8·5; and from zymotic diseases 2·4, out of which small-pox showed a rate of ·4. Dr. Browne in his monthly report states that the decrease which has taken place in the cases of typhus fever and small-pox is satisfactory, and leads to the fair inference that the fever which in May had a tendency to spread will not now assume an epidemic form, and that the small-pox which has prevailed for upwards of a year is slowly passing away.

*Cork.*—For the four weeks ending June 17th the births numbered 152, being equal to 23·09 per 1000; and the deaths to 90 or 14·93. Omitting the deaths of fifteen persons in the workhouse, and therefore outside the borough, who formerly had resided in the city, the urban death-rate was as low as 12·44.

### VITAL STATISTICS.

#### HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns, 5718 births and 3121 deaths were registered during the week ending the 15th inst. The annual death-rate in these towns, which in the two preceding weeks had been equal to 19·1 and 18·1 per 1000, was last week 18·4. The lowest rates in these towns last week were 14·1 in Norwich and Brighton, 14·9 in Birmingham, and 15·0 in Derby. The rates in the other towns ranged upwards to 23·7 in Bradford, 24·4 in Salford, 25·1 in Liverpool, and 26·0 in Leicester. The deaths referred to the principal zymotic diseases in the twenty-eight towns were 536, and exceeded by 66 the number returned in the previous week; 218 resulted from diarrhoea, 112 from whooping-cough, 83 from measles, 57 from scarlet fever, 44 from "fever" (principally enteric), 12 from diphtheria, and 10 from small-pox. The lowest death-rates from these diseases occurred in Norwich and Brighton, and the highest death-rates were recorded in Nottingham and Leicester. Whooping-cough showed the largest proportional fatality in Sunderland and Birkenhead; measles in Plymouth; scarlet fever in Derby and Hull; and "fever" in Hull. The fatality of diarrhoea, though still considerably below the average for the season, showed a marked excess in Leicester. The deaths referred to diarrhoea in the twenty-eight towns, which had been 70, 96, and 140 in the three preceding weeks, further rose to 218 last week, and were equal to an annual rate of 1·3 per 1000. The 12 deaths from diphtheria in the twenty-eight English towns were fewer than those returned in any previous week of this year, and included 8 in London and 2 in Portsmouth. Seven deaths were referred to small-pox in London and its suburban districts, 4 in Nottingham, one in Leeds, and one in Newcastle-upon-Tyne. The number of small-pox patients in the metropolitan asylum hospitals, which in the eleven preceding weeks had declined from 350 to 214, further fell to 204 on Saturday last; 23 new cases of small-pox were admitted to these hospitals during last week, against 29 and 30 in the two previous weeks. The deaths referred to diseases of the respiratory organs in London, which had been 212 and 173 in the two preceding

weeks, rose to 199 last week, and exceeded the corrected weekly average by 12. The causes of 74, or 2·4 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Leicester, Nottingham, Derby, Bolton, and Cardiff, while the proportion of uncertified deaths was largest in Preston, Salford, and Oldham.

#### HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which had been equal to 21·9 and 20·3 per 1000 in the two preceding weeks, rose again to 21·3 in the week ending the 15th inst., which exceeded by 2·1 the mean rate last week in the twenty-eight large English towns. The deaths referred to the principal zymotic diseases in these Scotch towns were 111 last week, and exceeded by 20 the number returned in the previous week; they included 56 from diarrhoea, 20 from measles, 14 from whooping-cough, 9 from diphtheria, 7 from "fever," 5 from scarlet fever, and not one from small-pox. The death-rate from these principal zymotic diseases averaged 4·7 per 1000 in the eight towns, and was 1·4 above the mean rate from the same diseases in large English towns. The 56 fatal cases of diarrhoea showed a further increase upon recent weekly numbers, and exceeded by no fewer than 36 the number returned in the corresponding week of last year; 32 occurred in Glasgow and 6 both in Dundee and Paisley. The mean death-rate from diarrhoea in the Scotch towns was last week nearly twice as high as that which prevailed in the English towns. The 14 deaths from whooping-cough in the Scotch towns showed a further decline from recent weekly numbers, but included 8 in Glasgow and 3 in Edinburgh. The fatal cases of measles, however, rose to 20, of which no fewer than 14 occurred in Dundee. The 9 deaths referred to diphtheria included 7 in Glasgow and 2 in Greenock; and 3 of the 5 fatal cases of scarlet fever occurred in Glasgow. The 7 deaths from "fever" showed a further decline from recent weekly numbers; 3 were returned in Edinburgh and 2 in Glasgow. The most noticeable feature of the week's returns is the excessive fatality of measles in Dundee; the deaths from this cause in this town, which had been 2, 8, and 4 in the three preceding weeks, rose to 14 last week. The deaths referred to acute diseases of the lungs in the eight towns, which had declined from 111 to 92 in the three previous weeks, were 95 last week, and were within 3 of the number attributed to these diseases in the corresponding week of last year.

#### HEALTH OF DUBLIN.

The rate of mortality in Dublin, which in the three preceding weeks had declined from 23·2 to 20·5, further fell last week to 16·8, a lower rate than has been recorded in any week since August, 1881. During the thirteen weeks of last quarter, however, the death-rate in the city averaged 26·8 per 1000, against but 19·5 in London and 20·5 in Edinburgh. The 112 deaths in Dublin last week showed a decline of 25 from those returned in the previous week, and included 5 which were referred to diarrhoea, 2 to measles, 2 to "fever," and not one either to small-pox, scarlet fever, diphtheria, or whooping-cough. Thus 9 deaths resulted from these principal zymotic diseases, against 14 in each of the two previous weeks; these 9 deaths were equal to an annual rate of but 1·3 per 1000, against 3·6 in London and 2·7 in Edinburgh from the same diseases. The 5 deaths attributed to diarrhoea corresponded with the number in each of the two preceding weeks. The 2 fatal cases of "fever" were 4 less than those returned in the preceding week. The two deaths from measles were the first returned since the commencement of the current quarter; in the first two quarters of this year, however, the fatal cases of this disease recorded in Dublin were 432 and 119 respectively. The causes of but 4, or 3·6 per cent., of the deaths in the week were uncertified.

#### BIRTHS AND DEATHS IN IRELAND.

During the quarter ended March 31st last, there were registered in the 801 Registrars' Districts in Ireland, 32,686 births, a number equal to 25·7 per 1000; and 24,873 deaths, representing an annual rate of 19·6. The returns for the quarter were of a very favourable character, the deaths being below those recorded in the corresponding quarter of last year to the extent of 3863, and the death-rate 2·1 lower.

The death-rate has not been so low at this period of the year since 1874. With the exception of the prevalence and fatality of measles in Dublin, and small-pox in Belfast and Waterford, there is nothing worthy of special notice in the returns.

### THE SERVICES.

**ARMY MEDICAL DEPARTMENT.**—Brigade Surgeon Robert Augustus Chapple to be Deputy Surgeon-General, vice J. Gibbons, C.B., granted retired pay; Surgeon-Major James Landale, M.D., to be Brigade Surgeon, vice R. A. Chapple; Surgeon Daniel O'Sullivan has been permitted to resign his commission.

**ARTILLERY VOLUNTEERS.**—1st Devonshire: Acting Surgeon Arthur Benjamin Ewen resigns his appointment.

**ENGINEER VOLUNTEERS.**—1st Flint (Buckley): Edward Williams, Gent., to be Acting Surgeon.

**RIFLE VOLUNTEERS.**—1st Cheshire: Acting Surgeon Isaac Byerley resigns his appointment.—17th Lancashire: Garnett George Tatham, Gent., M.D., to be Surgeon.—1st Linlithgowshire: Lieutenant James Hunter resigns his commission.—5th (West) Middlesex: Lieutenant Samuel John Wright to be Captain.—7th Middlesex (London Scottish): James Cantlie, Gent., M.A., M.B., to be Acting Surgeon.—8th Surrey: Richard Clement Lucas, Gent., M.B., to be Surgeon.

**ADMIRALTY.**—Staff Surgeon John Black Nicoll, M.D., has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet, with seniority of July 8th, 1882.

The following appointments have been made:—Fleet Surgeon John Breakey, to the *President*, additional, the appointment of Carr having been cancelled; Surgeon Thomas D. Popham, to the *Indus*; N. F. Hele, to be Surgeon and Agent at Orfordness in addition to Aldborough, vice Place; Surgeon John J. Diunis, M.D., to the *Hibernia*, additional, for temporary service at Malta Hospital; James Mill to be Surgeon and Agent at Fife Ness.

### Correspondence.

"Audi alteram partem."

#### THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS.

To the Editor of THE LANCET.

SIR,—In your article on the recent election at the College of Surgeons you rightly remark that the prospects of the representatives of the smaller schools are not exhilarating. Nevertheless, having survived my late defeat, I intend to come forward again next year, because I think that our smaller schools should be represented on the Council. In the meantime I hope you will again advocate what I believe to be the wish of the majority of the Fellows, that at these elections the votes of the Fellows should be taken by proxy instead of by ballot. If anything would prevent me from again coming forward as a candidate for the Council it is knowing that by so doing many Fellows who might wish to support me must be put to expense and inconvenience by having to vote in London. There are, however, other reasons why the election of members of the Council should be carried on by proxy. It is frequently impossible for men engaged in active practice to leave their patients for the day and come up to town to vote, so that in existing circumstances these Fellows are practically excluded from exercising their legitimate privileges. Again, if a rising feeling of discord on this matter between provincial and metropolitan Fellows can be averted by altering the system of voting, it must be advisable to make some such change as soon as possible. I am aware that the system advocated may not prove advantageous to the representatives of the smaller schools; I am convinced, however, that the principle is sound, and that the less fettered Fellows are as regards their power of voting the stronger will be the Council they elect. If these are the opinions held by the majority of Fellows on this subject, it is only necessary to represent the matter through the constituted authorities, and in proper form to the Privy Council, in order that we may secure an altera-

tion in the charter of the College. Proceedings of this kind, however, are expensive; it remains to be seen if any large number of Fellows (especially the provincial ones, for it chiefly concerns them) are willing to subscribe a sufficient sum of money to defray the necessary legal proceedings. The Council of the College of Surgeons can hardly be expected to recommend that the funds at their disposal should be expended in obtaining a new charter. It was, I think, upon these grounds the Council declined not long since to work in this matter.

I am, Sir, yours truly,  
Governor-street, W., July 17th, 1882. C. MACNAMARA.

## THE SHAFT SYSTEM OF SEWER VENTILATION.

*To the Editor of THE LANCET.*

SIR,—The adoption by the Town Council of Brighton of the plan of inducing sewer gas to escape into the air by means of funnels up the sides of houses induces me to mention a particular instance of the good effect of the system in this neighbourhood. About six years ago a street of colliery houses had been "favoured" at intervals with sudden outbreaks every hot summer during the previous ten years. The cause was easily ascertained. An enclosed drain, with the usual stench-traps, was within seven feet of the beds where the whole of the inhabitants slept. Every year there were several deaths from typhoid fever. Various plans were adopted: washing out the drains with pure water from a distance, brought in water casks, pulling down all outlying erections, &c. The results, although beneficial to a certain extent, were by no means satisfactory, and it was seriously proposed to take up the sewage-pipes and stench-traps and leave the place without any drains at all. In this state of matters the manager of the colliery proposed to erect a brick chimney at least thirty feet high, communicating with the drains, with the view of drawing the sewer gas away from the houses and dissipating it in the atmosphere at a considerable height. This was agreed to and carried out. During its erection the workmen frequently complained of the stench rising through the funnel of the tall chimney. This chimney was completed five years ago, and from that time to the present there has not been a single case of typhoid fever in the street. Still more, a colliery belonging to the same owners, four miles away, owing to its position and the houses being huddled closely together on the banks of a tidal river, charged with the filth of some uplying towns, was in summer time a focus for the germination of fever, deaths being common from it. The plan so successful in the street I write about was adopted, and, so far as can be judged in the time, the success has been similar. It appears to me that the plan of tall chimneys, like factory chimneys, adopted in large towns, in conjunction with the usual system of flushing with water, indicates a method likely to result in great sanitary success in the future. Funnels up the sides of houses evidently carry the gas to no great distance into the atmosphere, and the upper storeys and bedrooms of the town will receive the "benefit" of the plan, whatever that may be, whereas by carrying the poisonous gas fifty or possibly a hundred feet into the air excellent results are certain to accrue.

I am, Sir, yours truly,

ALEXANDER TROTTER, M.D.

Blyth, Northumberland, July 17th, 1882.

## PUERPERAL CONVULSIONS: ARTIFICIAL RESPIRATION SUCCESSFULLY USED.

*To the Editor of THE LANCET.*

SIR,—So far as I am aware the matter treated in the following lines is new, and may be regarded as of sufficient public interest and utility to merit being placed on record in your pages:—

On June 18th I attended A. P., aged twenty-two, a primipara. She was of a stout, florid, and somewhat apoplectic appearance; and, as I afterwards learned, more than one of her family (including her mother) had had "a stroke." She seemed in good health and spirits, but as the os was only very slightly dilated, I retired after giving a few general instructions, and telling the nurse to send for

me when matters were more advanced. Next morning at 8 o'clock I was sent for, and on arrival found the head well in the pelvis. The pains were strong and regular; but after waiting about three hours, and finding no perceptible progress, I applied forceps. After half an hour's hard traction during the pains, which were very frequent, there did not seem to be the slightest progress, and I was deliberating as to further measures, when I noticed that her limbs were quite rigid. Looking at the face I found her in a strong convulsion, and the face almost black, the rest of the body rapidly assuming a dusky hue. I at once looked for my chloroform bottle, which, however, had been removed from my bag. There was no time to be lost, as she appeared every second to be getting more rigid and the asphyxia more marked, so I instantly removed the forceps, turned her on her back, and proceeded vigorously to apply artificial respiration. The effect was as gratifying as it was rapid; the thorax began to take part in the work of respiration, the cheeks and lips to regain their colour, and a deep sigh resulted in an almost sudden return to her natural appearance. The spasms ceased, and she rapidly regained consciousness, being, however, confused, and her speech being thick and inarticulate. I allowed the labour to proceed without further interference (dreading a return of the convulsions) for about two hours longer, when, there being no sign of progress, I reluctantly decided to give the forceps one more trial. This time it was successful, and in half an hour the head was born. I took off the forceps, and was giving her a little rest, when suddenly she was again seized with a convulsion. I immediately extracted the child, and, placing the patient once more on her back, recommenced artificial respiration, and with equally satisfactory results. The patient made a good recovery without further mishap.

I am not aware that this method of treatment has been adopted before. I can find no reference to it in any of my text-books, and it appears to be new to all medical friends to whom I have mentioned it. The rationale of the matter would appear to me to be that the convulsion was caused by reflex irritation throwing off its balance the nervous supply of the respiratory muscles (or, what is practically the same thing, the respiratory centre), which balance was restored by the process of artificial respiration.

Yours, faithfully,

K. W. MILLICAN, L.R.C.P., &c.

Kinaston, Warwick, July, 10th, 1882.

## "THE OPERATION OF 'SPAYING' IN WOMEN."

*To the Editor of THE LANCET.*

SIR,—Your comments on Mr. Lawson Tait's position and procedure in relation to the case of Mrs. A., narrated in my letter which you kindly inserted in your issue of July 8th, and the inference of necessity suggested thereby, are certainly, in my opinion, unfair to that gentleman; for if removal of the ovaries in Mrs. A.'s case was unjustifiable from any point of view, it is I, and not Mr. Tait, who is in fault. He operated as a skilled surgeon under my direction as medical attendant on the case. I laid before the patient and her friends the risks, both immediate and remote, and the impossibility of pregnancy subsequent to it; and I made no promise that complete restoration to health would follow; but I strongly expressed the opinion, based on several years' attendance on her, that the ovaries were in a state of chronic disease, from which nothing but removal would relieve them. That this opinion was well founded no one who saw them after removal would for an instant doubt. Having thus clearly defined the position taken by Mr. Tait and by myself in this case, the question which arises from your editorial comments is undoubtedly this: Given a patient under the climacteric age, with a history of twelve years' suffering, including several severe attacks of ovaritis; menstrual period most irregular, sometimes with six or eight months' interval, often with delirium and hallucinations at its recurrence, sleeplessness, emaciation, and entire incapacity for any duty or pleasure—is it, or is it not, justifiable to remove the organs which it is believed are the seat of disease and the cause of ill-health? It is easy to be wise after the event, and to say at the post-mortem, "If this woman's ovaries had been removed she might have lived." To my mind, credit, rather than reproach, is due to the advisers and operator who, recognising the disease, and, as they believe,

the only remedy, prevent the need of that autopsy. Many besides myself will take exception to the vague and undefined expression used in your comment on Mr. Tait's letter of July 1st—namely, "We mean the operation Mr. Tait has been performing for some time past." Permit me to say, Sir, that thoughtful and unprejudiced men will attach but little value to such a general accusation, unsupported by reference to any particular case, or class of cases; and I would respectfully ask you, Sir, in justice to Mr. Tait and to your readers, to explicitly indicate the cases you refer to; and if in the case of Mrs. A—— you would inform me as to what alternative should have been adopted in place of operation I and, I feel sure, many others will be most grateful for the instruction.—I am, Sir, yours faithfully,

Milford, Hants, July 12th, 1881. DOUGLAS W. ESHELBY.

\* \* We are very reluctant to prolong this discussion; but we must demur to Dr. Eshelby's contention as to the responsibilities of practitioners in operations. The circumstances of any case must be very exceptional and peculiar that can justify a surgeon, however skilful, in undertaking the performance of an operation against his deliberate judgment.—ED. L.

### SMALL-POX AND VACCINATION.

*To the Editor of THE LANCET.*

SIR,—Referring to your remarks in last week's issue of THE LANCET on this subject, will you allow me to state that the evidence which my predecessor, Mr. Marson, gave before the Select Committee on the Vaccination Acts in 1871—viz., that no nurse, servant, or other official of this hospital had ever suffered from small-pox during his tenure of office, then a period of thirty-five years—still holds good, making now forty-six years in which the *employés* of this hospital have enjoyed absolute protection from this disease. Since I was appointed surgeon to the hospital no patient has been engaged here either in the capacity of nurse or servant, and, so far as I can gather, it has always been the exception to engage patients. The number of those in the service of the hospital who have been protected by previous attacks of variola I should estimate at about 7½ per cent. I cannot pretend to explain the extraordinary immunity thus enjoyed, I am simply desirous of adducing facts; I cannot but attribute it largely, however, to the circumstance that there has been throughout the period alluded to a station for gratuitous vaccination in connexion with the hospital, so that the surgeon is not dependent on extraneous sources for his lymph supply, and thus only uses for his revaccinations lymph of the activity of which he is absolutely assured.

I am, Sir, yours obediently,

HERBERT GOUDE, F.R.C.S. Edin.

Small-pox and Vaccination Hospital, Highgate-hill,  
Upper Holloway, N., July 18th, 1882.

### DISLOCATION OF FOOT BACKWARDS.

*To the Editor of THE LANCET.*

SIR,—It may be of interest to record that on June 10th last I met with a case of dislocation of the foot backwards, exactly similar to that mentioned by Mr. Ashmead in this week's issue of THE LANCET. The patient when running caught the heel of his boot on the edge of the kerb, the foot being thus suddenly stopped while the body was still carried forwards. I saw him about half an hour after the injury, which was on the right side, and found a well-marked dislocation of the foot backwards. The lower end of the tibia could be seen prominent on the dorsum of the foot, the tendo Achillis standing well out in relief and raising the heel. In this case also the fibula was fractured at the lower end. Reduction was fairly easily effected without chloroform, and for the first few days the leg was put up in lateral wooden splints, afterwards in plaster-of-Paris.

I am, Sir, yours, &c.,

HENRY N. HOLBERTON, L.R.C.P. Lond., &c.  
Eastbourne, July 8th, 1882.

THE funds of the Wolverhampton and Staffordshire Hospital have just been augmented by the gift of £1000 by a member of the weekly board of the hospital.

### SCOTTISH NOTES.

*(From our Correspondent.)*

DR. GEORGE DICKIE, ex-Professor of Botany in the University of Aberdeen, died at his residence in that town on Saturday last. The deceased gentleman was educated wholly at Aberdeen, where, after graduating, he commenced practice. Routine medical work proving uncongenial, he devoted himself entirely to the study of natural science, and was soon successful in obtaining the Botany Chair in the Belfast College. On the amalgamation of King's and Marischal Colleges, in 1860, Dr. Dickie was appointed to the same position in the University of Aberdeen, and he held this office till his retirement, from ill-health, in 1877. Though scarcely a brilliant lecturer, his students felt that he had a deep knowledge of his subject, and the devotion to science which he imparted was, perhaps, better than many dry facts. While an enthusiastic botanist, he felt that his favourite pursuit need have but a subsidiary part in the equipment of a practical physician, and hence his objection to remit a man to his studies who showed a good acquaintance with the more purely medical subjects. His students gave him their warm personal regard, and his death, though at an advanced age, will be keenly felt by many of them.

I regret to hear that Dr. Alex. Ogston, who has already been laid aside for about three months, is still unable to resume work. He purposes visiting the Continent shortly to recruit.

Though the zymotic death-rate has not been markedly heightened as yet, the returns of the various authorities show that Aberdeen, Dundee, and Perth are at present suffering from epidemics of measles, typhus, and typhoid fevers respectively. In the northern city the medical officer states that the epidemic of measles "has quite got over the sanitary staff," and typhus has made several attempts to break out. In Dundee during last month over 400 cases of zymotic disease were notified, the large majority being measles, but about twenty cases of typhus were included. In a town with such a sick-rate the authorities gravely consider whether £150 is a sufficient salary for their medical officer of health. It will be a misfortune to the town if a short-sighted parsimony debar it from obtaining the services of a first-rate man. The Perth people labour under the peculiar hallucination that pure water can be obtained from the river just after their whole sewage is thrown over the filter-bed, while strangers wonder that typhoid fever is ever absent. The Board of Supervision recently sent an inspector to inquire into the truth of certain severe strictures which had been passed upon the Police Commissioner, and as the result of that gentleman's investigations goes to support the outside criticism, both the authorities and the medical officer have written elaborate reports which go to prove that they have not been wholly unmindful of health interests. The result of all this will probably be that the sewage will be carried so far down the river that it will no longer prove so serious a nuisance.

### IRELAND.

*(From our own Correspondent.)*

A PUBLIC meeting of the Senate of the Royal University of Ireland was held last week for the purpose of conferring degrees. At the close of the proceedings the Vice-Chancellor of the University, Lord O'Hagan, said it gave him the greatest pleasure to meet the first graduates of the university. He wished them every prosperity in their future career; and he felt confident that they would do honour to their university, and to the noble profession which they had embraced. A tolerably large number of candidates presented themselves at the recent examinations, and there would have been more were it not for a misunderstanding in relation to some of the regulations of the new university.

The annual report of the Richmond District Lunatic Asylum for the past year shows that during 1881 there were 1446 inmates under treatment, of whom 424 were admitted during the year. The deaths numbered 158, three being cases of suicide; and the percentage of deaths on the total

number in the asylum was equal to 10 $\frac{1}{2}$ %. As regards the social condition of the 1039 lunatics in the asylum on the last day of December, 198 were married, 638 single, 47 widowers and widows, and in 156 instances it was unascertained. The remarkable discrepancy which exists between the numbers of married and single inmates of asylums in Ireland has often attracted attention, but no satisfactory explanation has ever been attempted. Dr. Lalor, the medical superintendent, states that his experience of the past year, as of former years, has confirmed his confidence in the advantages of treating the insane in large, in place of small, asylums, and in a few large classes or divisions instead of numerous small classes. Restraint, and the instruments for its infliction, have been totally disused—indeed, have been unknown—since his appointment, in 1857, and the education, employment, and amusement of the insane in large associated classes have more and more come to the front as preferable methods to the isolation and non-occupation which were at one time thought necessary, or even desirable.

Last week Mr. John Ryall, a student of the Rotundo Lying-in Hospital, Dublin, was accidentally killed by a bullet from a revolver which he was in the habit of carrying, and which in some way exploded. The bullet entered the right groin, and death occurred from hæmorrhage. The foolish custom of carrying revolvers prevails to such an extent at present in Dublin that it is surprising more accidents have not resulted from this cause.

A death from lightning took place at the Carragh a few days since. Private Harris was struck on the left side, and his uniform from the breast down to his foot was completely torn away, one of his boots being rent in pieces. Death was instantaneous; but a comrade who was with him at the time and was also struck by the lightning is under treatment at the hospital.

The annual report of the Cork Maternity Association shows that upwards of 400 women were relieved last year at the small outlay of some £120. It was stated at the annual meeting that in proportion to the population of the town the Cork Maternity relieved more women than any other similar institution in the kingdom, and that the percentage of deaths was one of the lowest recorded. These are claims for increased support, and it is to be hoped that this year the receipts may not fall short of the expenditure, as was the case, I regret to say, last year.

The last victim to agrarian outrage in Ireland is a Mrs. Connell, who resided near Claremorris. Her cowardly assailants, concealed behind a hedge, fired on the deceased and a bullet penetrated the wrist. Tetanus supervened and death resulted.

The recommendation of the Public Health Committee, and of the committees appointed by the North and South Dublin Board of Guardians, to abolish the port hospital ship, has been confirmed by the Dublin Corporation.

## PARIS.

(From our Special Correspondent.)

WITH Amadée Latour a medical writer of no small interest has passed away. Following in the steps of Reveillé-Parise, and Peisse, Latour devoted himself especially to the *Feuilleton*, a chatty anecdotic review of current events, and his *causeries* have always contributed in a large measure to the popularity of the different journals with which he has been connected. After successively editing the *Journal Hebdomadaire*, the *Presse Médicale*, and the *Journal des Médecins Praticiens*, he was appointed in 1847 to the direction of the *Union Médicale*, and filled this post until a few months since, when he was obliged, through ill-health, to relinquish work. Amadée Latour was an easy and productive writer. Under the pseudonym of "Docteur Simplex," his Saturday *feuilletons* formed one of the chief attractions of the *Union Médicale*, and besides these he was in the habit of contributing a large number of leading articles, reports of learned societies, and bibliographic notices. This superabundance of editorial work for a publication which appears three, and sometimes four, times a week, whilst it made him an accomplished journalist, accounts for the paucity and mediocrity of his other productions, which consist only of a few notes and memoirs, now almost entirely forgotten. The chief of these is a

treatise on the Preservative and Curative Treatment of Pathosis. But it is not only as a medical reviewer that Amadée Latour will be remembered. He was the founder of the Association Générale des Médecins de France, and it is mainly due to his constancy in advocating the cause that the useful institution owes its present prosperity. He was rewarded somewhat late in life by the cross of the Legion of Honour, and the Academy of Medicine had the good sense to elect him to sit amongst its members.

The last number of the *Gazette Hebdomadaire* contains an article by Dr. A. Dumès upon the efficacy of fumigations of ox-gall in cases of acute hemeralopia. This treatment is by no means new; for, as the writer points out, it dates back as far as Hippocrates, and possibly even before his time amongst the Chinese. But, like a good many other useful methods, it has been superseded in modern practice. A recent writer upon ocular therapeutics (De Wecker) makes no allusion to it. Dr. Dumès reminds his readers that it was a favourite remedy with Fossagives, and the observations which he publishes certainly endorse its value. It may be mentioned that some indications concerning the use of ox-gall are to be found in the Medical Digest by Dr. Neale.

M. Hillairet read a report at the Academy of Medicine on the isolation of children suffering from infectious diseases. He recommends that a definite period of separation be fixed for each disease, and that no child be allowed to return to school after an infectious illness without a medical certificate that the period of probation has been passed. The conclusions are as follows:—(1) Children affected with varicella, variola, scarlatina, measles, diphtheria, or mumps, should be strictly isolated from their comrades. (2) The period of isolation should be forty days for variola, diphtheria, scarlatina, and measles, and twenty-five days for varicella and mumps. (3) The convalescent should be well combed before he returns to his playmates. (4) The clothes worn at the beginning of the illness should be heated in an oven to 90° Centigrade, submitted to sulphurous fumigations, and properly cleaned. (5) The bedding, carpets, furniture, and walls of the sick room should be washed, aired, and disinfected. (6) Any child who shall have suffered from any of the affections before mentioned, must produce a medical certificate that these requirements have been complied with before he be allowed to return to school.

M. Bourrel, a veterinary surgeon of Paris, proposes to prevent the transmission of hydrophobia by rendering the teeth in dogs similar in shape to those of the herbivora. He says that the latter animals never transmit rabies, because the free extremity of the tooth is blunt, and merely compresses the epidermis, without lacerating it, whereas the canine and incisive teeth of the dog cut into the tissues. The slight operation necessary for this purpose is most simple, and can be performed in a few minutes. It gives rise to no disturbance at the time, and does not interfere with future dentition. M. Bourrel states that he exposed his hand, covered by a glove as a precaution, to a rabid dog that had been subjected to the operation. The animal immediately seized hold of it and bit for some time. When it let go the glove was whole, the bite having only produced an indentation. *Faute de mieux*, the experiment is worth a trial.

M. Martineau continues to use hypodermic injections of ammoio-mercuric peptone on a large scale in the treatment of syphilis. During the last fourteen months he has made 11,000 injections in 600 patients, without producing any inflammation, abscess, or other bad symptom. He says that neither mercurial cachexia nor salivation is to be feared when mercury is administered in this manner, as it is rapidly excreted by the kidneys. Under the influence of this treatment the blood-cells increase in eight days to the normal (four to five millions), and there is a gain of weight to the amount of from one to five kilogrammes. A speedy result is obtained in cases of iritis and irido-choroiditis. M. Luton of Reims uses metallic mercury in the same manner. He injects by means of a gutta-percha syringe, provided with a steel needle, five or six drops of mercury into the substance of muscles of the thigh, the acidity of these structures ensuring its absorption.

Whatever the French peace-at-any-price politicians may think of the change of front of the Government, French subjects abroad are likely to approve of the manly policy adopted by M. Freycinet. In medical circles there is a strange story going the rounds about a fatal accident which occurred lately in Constantinople in consequence of an error in prescribing. The Turkish authorities, getting wind of the

matter, summoned the three consultants and the chemist to answer the charge of wilful murder. Two of the medical men and the chemist referred at once to their consuls, and the charge was forthwith changed into one of manslaughter. The third, a French physician, after vainly attempting to obtain help from the representative of his Government, thought it best to fly, and escaped in a boat to Varna at the risk of his life. This case would seem to show that there is more virtue in ironclads than conferences. It is difficult to conceive of an Englishman being obliged to fly from a country with which his Government was at peace because his consul was unable to shield him from the consequences of a false accusation.

### MEDICAL NOTES IN PARLIAMENT.

In the House of Commons on Thursday, the 13th inst., a petition for exemption of medical men from the carriage duty was presented from the Vale of Clwyd; and a petition for redress of grievances was presented from a number of militia surgeons. The North of Ireland Branch of the British Medical Association petitioned in favour of the Union Officers' Superannuation (Ireland) Bill.

#### *Vaccination Inquiry at Norwich.*

Mr. Dodson stated, on Friday, in reply to Mr. P. A. Taylor, that Dr. Airey, one of the Local Government Board inspectors, was holding an inquiry at Norwich into the allegations connecting the death of four children and the illness of four others from the effects of vaccination. The parents would not be allowed to be legally represented at the inquiry, but a full opportunity would be given them of making their own statements.

A return was presented, on the motion of Mr. Ecroyd, showing the hours of labour and the regulations for factories in foreign countries. A return was ordered, on the motion of Mr. Hibbert, of copy of the annual report of the Assistant Commissioner of the Police of the Metropolis for the year 1881 relating to the Contagious Diseases Acts.

#### *Pollution of the Thames.*

On Monday, Sir G. McGarel Hogg, in reply to Mr. Briggs, stated that the Metropolitan Board of Works had decided upon enlarging the sewage reservoir and outfall at Barking, with the view of obviating the necessity which had sometimes arisen of turning sewage into the river before high water; but since the appointment of the Royal Commission of Inquiry, the Board had postponed proceeding with the works for three months.

#### *Treatment of Irish Prisoners.*

Mr. Trevelyan, replying to Mr. Sexton, stated that the account of the treatment of eleven prisoners in Galway, which was referred to in last week's LANCET, was exaggerated. The men all had frieze coats to protect them from the weather, and although it was necessary to secure them in a strong room, they were not refused water, and they had also bread-and-butter given them. There was no confirmation of the allegation that one of them fainted from want of air.

A petition was presented from Dublin for inquiry into the case of militia surgeons. A petition was presented from Mr. John Smith for inquiry into private lunatic asylums.

#### *The Royal University of Ireland and the Medical Council.*

Dr. Lyons moved the second reading of the Medical Act, 1858, Amendment Bill.—Mr. Serjeant Simon objected, as it was past the hour when opposed business could be taken.—Dr. Lyons, however, persuaded the hon. member to withdraw his objection, by pointing out that the object of the Bill was simply to authorise the Royal University of Ireland to elect representatives to the Medical Council, and that it had the assent of the Government, and of the right hon. gentleman opposite who represented Dublin University.—The Bill was then read a second time.

On Tuesday, a petition in favour of the Infectious Diseases Notification Bill was presented from Sleaford.

#### *The Contagious Diseases Acts.*

On Wednesday, Mr. Stansfeld presented a number of petitions in favour of the repeal of these Acts. One of the

petitions, he said, was signed by a majority of the members of the medical profession in Belfast. The right hon. gentleman afterwards moved the second reading of his Bill for repealing the Acts in question, and in the course of his speech declared that from a hygienic point of view they were the greatest imposture ever known.—Mr. Childers moved the "previous question," on the ground that the Select Committee had not yet reported, and this was supported by Sir S. Northcote and Mr. O'Shaughnessy.—The previous question was agreed to, and the Bill accordingly dropped.—In anticipation of the somewhat unsavoury character of the debate, an attempt was made by one or two hon. members to clear the ladies' gallery, but it was unsuccessful, and a considerable number of ladies, presumably members of the Association for the Repeal of the Acts, remained to listen to the speeches.

On Thursday, a petition was received from Halifax in favour of the Infectious Diseases Notification Bill.

Mr. Moore's motion for a return of emigrant ships and their medical officers, which has been so long "blocked" on the paper, was at last agreed to.

Mr. Corbet gave notice that he will ask when the report of the inspectors of Irish lunatic asylums for the year ending March 31st will be presented.

## Obituary.

### THOMAS OLIVER DUKE, M.R.C.S., L.S.A.

THERE died at Clapham on June 5th one of the fast disappearing class of old-fashioned general practitioners who have done so much to win the confidence of the people for our profession. Mr. Thomas Oliver Duke was born in Sussex in the year 1818. He received his earlier medical education at Winchester Hospital under Mayo and Lyford, and he there acquired a sound preliminary knowledge of anatomy and surgery. Entering Guy's Hospital, he won at the end of his first winter session the gold medal for anatomy, which usually fell to a student who had completed his second year's studies. As soon as he had passed the College and Hall examinations he devoted himself to general practice and settled at Kennington, where, and at Clapham, he practised for forty-two years. For the first fifteen years of this period he was surgeon to the Lambeth Workhouse, but his ideas of what were the rights of the poor brought him into collision with the guardians. In the contest which ensued he was supported by the leading inhabitants of his district, who paid by subscription the expenses connected with a vexatious lawsuit which resulted from his protests against the conduct of the master of the workhouse. He believed in himself and in his power to alleviate and cure disease, whilst the warmth, zeal, and disinterestedness with which he threw himself into his work, together with a singularly handsome presence and winning manner, attached to him a wide circle of patients, who placed absolute confidence in him, and many of whom regarded him with a respect which almost amounted to reverence. It is perhaps to be regretted that he did not devote himself to pure surgery, for which his knowledge of anatomy, his great manual dexterity, his strong common sense, and never-failing presence of mind particularly fitted him. He had for some years been failing in health, but had in no way succumbed, and his death after a few weeks' illness from granular kidney, impacted renal calculus, and great hypertrophy of the heart, fell as a sudden shock on his family and friends.

### GEORGE HAMILTON, M.D., L.R.C.S. EDIN.

BY the death of Dr. Hamilton of Falkirk, which occurred at the old manse on Tuesday last, Scotland has lost one of its foremost country practitioners. Dr. Hamilton was busily engaged in practice up till a few days before his death, and though of advanced age retained a wonderful vitality. A native of Edinburgh, he was wholly educated there, receiving his M.D. in 1833 as well as his licence from the College of Surgeons. He practised for nearly half a century in Falkirk and gained a large share of public and professional support. Professionally he was best known by his various writings on

subjects connected with midwifery, and he has done more than any man in Scotland to bring about the present more common use of forceps in midwifery practice. In 1853 he wrote his first paper on the subject, and since then in various medical journals and at the Obstetrical Society in Edinburgh he has continued to urge the more frequent use of the instrument. Up till 1878 Dr. Hamilton used the forceps in about one out of six cases, but latterly he employed the instruments much more frequently. He was the medical attendant of the Institution for Imbeciles at Larbert, and of Campbell Simpson's Asylum at Plean. Dr. Hamilton's three sons have all followed their father's profession, the recently appointed Professor of Pathology in the University of Aberdeen being his second son.

#### RICHARD SUTTON HARVEY, F.R.C.S. ENG., J.P.

OUR list of deaths this week contains the announcement of the decease of Mr. Harvey, who was well known to the medical profession of Lincolnshire and the adjoining counties. Mr. Harvey was born at Pointon, Staffordshire, in March, 1803. He attended the Middlesex Hospital and the Windmill-street School of Medicine, and in 1826 qualified as M.R.C.S. and L.S.A., while thirty-two years later, in 1858, he was elected a Fellow of the Royal College of Surgeons of England, and in the same year obtained the Fellowship of the Edinburgh College. He was the first house-surgeon of the Lincoln General Dispensary, and, after holding the appointment about two years, entered into practice in Lincoln, which he conducted with great success for nearly forty years. Some years ago the deceased retired from practice and enjoyed a well-earned repose. Mr. Harvey was for many years a member of the Corporation, first as councillor and afterwards as alderman; and he thrice filled the civic chair. During his last mayoralty a substantial testimonial, consisting of his portrait and a service of plate, altogether costing between £500 and £600, was presented to him. The deceased was also the senior justice of the peace for Lincoln.

## Medical News.

#### ROYAL COLLEGE OF SURGEONS OF ENGLAND.—

The following gentlemen, having passed the required examination for the Diploma, were admitted Members of the College at a meeting of the Court of Examiners on Monday last:—

Ashdown, Herbert Harding, M.B. Edin., Edinburgh.  
Bilton, Joseph Shephard, M.B. Edin., Finstock, Oxon.  
Culler, Joseph, L.S.A., Manchester.  
Dobie, William Henry, M.B. Edin., Chester.  
Hyrons, Ernest Augustus, L.R.C.P. Edin., Padmore.  
Jameson, Granville, M.B. Edin., Heywood, Manchester.  
Keep, Arthur Corrie, M.B. Edin., Wollaston.  
Miles, Bernard Langley, M.B. Edin., Edinburgh.  
Nash, John Brady, M.B. Edin., New South Wales.  
Neve, Ernest Frederic, M.B. Edin., Hurstlerpoint.  
Nicolson, Malcolm Alex., M.B. Toronto, East Dulwich.  
Parkinson, Chas. Joseph, L.S.A., Greenhays, Manchester.  
Pasterson, George de Joneourt, M.B. Dub., Dublin.  
Price, William Elliott, M.B. Durh., Hereford.  
Roy, Silva Prasad, M.B. Calcutta, Calcutta.  
Sinha, Narendra Prasanna, L.M. Bengal, Calcutta.  
Stapleton, Joseph John, M.B. Edin., New South Wales.

The following gentlemen were admitted Members of the College on Tuesday last:—

Chudwick, Charles Montague, L.S.A., Tunbridge Wells.  
Hendley, Harold, Hammersmith.  
Horrocks, William Heaton, Bilton, Lancashire.  
Lessey, Sandford Scobell, Ealing.  
Mends, Bowen Stilon, Blackheath.  
Milton, H. M. Nelson, L.S.A., Clapham.  
Montford, James, L.R.C.P. Edin., Church Stoke.  
Masgrave, Frank Ernest, Leeds.  
North, John Howard, Walsall.  
Perkins, Alfred Temple, L.R.C.P. Edin., Stoke Newington.  
Preston, George, Barton, near Manchester.  
Price, John Dudley, Dudley.  
Scatchard, Walter, Boston Spa.  
Waldy, John, Darlington.  
Wilkinson, William Camac, Sydney, New South Wales.  
Wilson, Arthur Henry, Islington-square, Liverpool.  
Withers, John Sheldon, Sale, Cheshire.

The following gentlemen were admitted Members of the College on Wednesday last:—

Audland, William Edward, MIlnthorpe.  
Challinor, Cedric, Bolton.  
Cuthane, F. J. Fitzgerald, Hastings.

Dingley Edward Alfred, Sherborne, Dorset.  
Donnet, J. J. Conway, Dover.  
Drew, Hedley Vicars, Gloucester-place.  
John, David, Swansea.  
Jones, David Llewelyn, Llandilo, South Wales.  
Lowe, Thomas Pagan, Burton-on-Trent.  
Morris, Charles Arthur, Lower Norwood.  
Penn, John Evans, Plymouth.

The following gentlemen passed the Primary Examination in Anatomy and Physiology at a meeting of the Board of Examiners on the 13th inst.:—

A. G. A. Barker and Thomas Phillips, University College; Charles A. Mac Anally and E. R. B. Archer, Guy's Hospital; T. A. B. Soden, London Hospital; James B. Sutton, Charing-cross Hospital; Chas. P. Maquire, Dublin.

Of the 252 candidates examined during the past fortnight, 88 failed to satisfy the Board, and were referred for three, and 13 candidates for six, months' further anatomical and physiological study.

#### ROYAL UNIVERSITY OF IRELAND.—

The following Degrees were conferred last week by the Vice-Chancellor, Lord O'Hagan:—

**DOCTOR IN MEDICINE.**—Percy Allport, Martin Henry Atcock, Thomas Cahill, William Courtney, Timothy Joseph Crowley, Pierce Joseph Daly, Luke Gerald Dillon, Patrick Joseph Galloway, John C. Hackett, William Edward Hadden, Henry Aymer Hales, Samuel Hamill, Samuel Hamilton, Chas. James Holmes, James Macgregor Lithgow, Connor Joseph O'Loughlin Maguire, Robert Carmichael Moore, Patrick O'Gorman, Thomas H. O'Shaughnessy, John Mortlock Phillips, Leonard Robinson, George Atkins Rountree, Arthur W. Sandford, James M. F. Shine, Samuel Stronge, John Wilgar Taylor, Joseph H. Whelan, John W. Williams, James Vance Young.

**MASTER OF SURGERY.**—Percy Allport, Thomas Cahill, Wm. Courtney, Timothy J. Crowley, Chas. Daly, Pierce Joseph Daly, Luke Gerald Dillon, John C. Hackett, William Edw. Hadden, Samuel Hamilton, Chas. J. Holmes, Samuel William Johnson, William Kelly, Daniel Lehane, Edward M'Cinnell, John J. M'Cormick, Connor Joseph O'Loughlin Maguire, Robert Carmichael Moore, Thos. H. O'Shaughnessy, Ferdinand A. Purcell, Leonard Robinson, Robert Leonard Rutherford, Arthur W. Sandford, Jas. M. F. Shine, Samuel Stronge, John Wilgar Taylor, Joseph H. Whelan, John W. Williams, Charles Wiseman.

**DIPLOMA IN MIDWIFERY.**—Percy Allport, Thomas Cahill, James Craig, Timothy J. Crowley, Pierce J. Daly, Patrick J. Galloway, John C. Hackett, William Edw. Hadden, Chas. J. Holmes, William Nelson, Arthur W. Sandford, Jas. M. F. Shine, Joseph H. Whelan, Chas. Wiseman.

**COLLEGE OF PHYSICIANS IN IRELAND.**—At the July examinations the following obtained the Licences in Medicine and Midwifery of the College:—

**MEDICINE.**—Alfred Benjamin Bake, Walter Boyd, Sydenham Davis Chandless, Austin Nathaniel Cooper, John Crimmin, Owen Henry Evans, Alexander Fleming Harper, Robert John Healy, John Jas. Irvine, John Henry O'Dowd M'Guinness, John M'Mullan, John Robert Mallins, Katherine Sara Mitchell, Julia Caroline Mitchell-Swaagman, Mathew Flood O'Reilly, Robt. James Tate, Wm. Henry Stoney Walker, David William Whitfield, Michael Thomas Yarr.

**MIDWIFERY.**—Edm. MacWilliam Bourke, Sydenham Davis Chandless, Austin Nathaniel Cooper, John Crimmin, Owen Henry Evans, Alex. Fleming Harper, Alfred Adolphus Hayes, Robt. John Healy, John James Irvine, John H. M'Guinness, John M'Mullan, John Robert Mallins, Katherine Sara Mitchell, Julia Caroline Mitchell-Swaagman, William Reith Scroggie, Robert James Tate, William Henry Stoney Walker, David William Whitfield, Michael Thomas Yarr.

**APOTHECARIES' HALL.**—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on July 13th:—

Duff, Charles Henry, Gray's-Inn-road.  
Howse, Percy William M'Dowall, London Hospital.  
Munckton, Alfred, Lydiard, St. Lawrence.  
Parkinson, Charles Joseph, Manchester.  
Parsons, Charles Wm., The Crescent, Cpland-road, Hackney.  
Reynolds, James Jones, Stoke-by-Clare, Suffolk.  
Ryan, Thomas, Scarborough.

The following gentlemen also on the same day passed the Primary Professional Examination:—

John James Langston, London Hospital; Wm. Frederick M'Donogh, Westminster Hospital; V. Harold W. Wingrave, Middlesex Hospital.

**UNIVERSITY OF LONDON.**—At the Matriculation Examination held last month 66 candidates passed in the honours division, 371 in the first, and 66 in the second.

**HASTINGS CONVALESCENT HOME.**—The Prince of Wales has forwarded a donation of fifty guineas to the Home, of which his Royal Highness has consented to become patron.

**PRESENTATION.**—The governor, chaplain, and officers of H.M. Prison, Kirkdale, have presented Dr. James Barr, the medical officer, on the occasion of his marriage, with a pair of handsome bronzes, accompanied with an illuminated congratulatory address.

WHILE bathing in the Holy Loch, near Sandbank, Firth of Clyde, a few days ago, Mr. Morehead Macfarlan, M.R.C.S., was seized with a fit. Although he was got out of the water alive, he died almost immediately afterwards.

**RICHMOND HOSPITAL.**—Her Royal Highness the Princess Mary Adelaide, Duchess of Teck, has consented to open the new wards of the hospital on Saturday, July 22nd, at 3.30 P.M., and to receive purses containing not less than five guineas in aid of the building and furnishing funds.

ON the 10th inst. the foundation stone of the Torquay Sanitary Hospital was laid by Mr. William Kitson, donor of the site, in the presence of the members of the Local Board and others. The estimated cost of the building is about £3000. The pavilion system will be adopted.

THE death of Mr. J. P. Crosby, L.R.C.P. Ed., medical officer of the Sunderland Workhouse, took place suddenly on Monday last. An inquest having been held on the body, a verdict was returned of "Death from an overdose of morphia." It appears the deceased had been accustomed to resort to the use of the drug as a remedy for sleeplessness.

**THE GREAT NORTHERN HOSPITAL.**—Lord Cowper presided at a meeting in support of the claims of this hospital on Wednesday evening, in the Athenaeum, Highbury. He testified to the care with which the patients were treated. Dr. Cholmeley stated that as regarded the alleged abuse of the out-patient department of hospitals, great care had been taken to check this abuse at the Great Northern over a period of five years, and that only seven per cent. of cases were found unfit.

**SANITARY INSTITUTE OF GREAT BRITAIN.**—At the anniversary meeting held at the Royal Institution on Thursday, July 13th, his Grace the Duke of Northumberland in the chair, an address was delivered by E. C. Robins, F.S.A., F.R.I.B.A., entitled "The Work of the Sanitary Institute of Great Britain." The author specified the objects had in view by the Society and the way in which it had sought to carry them out, and mentioned some points which he regarded as worthy of attention by sanitarians. A vote of thanks was passed to the lecturer.

**SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.**—On Wednesday, July 12th, a quarterly court of directors of the above Society was held at 53, Berners-street, in the Library of the Royal Medical and Chirurgical Society. Sir George Burrows, Bart., the President, took the chair punctually at 5 P.M. A sum of £1291 10s. was voted to be distributed among sixty-two widows, seven orphans, and three orphans on the Copeland Fund. The expenses of the quarter were £44 7s. 6d. Seven new members were elected, the deaths of four reported, and two had ceased to be members. Fresh applications were read from three widows and one orphan, and the death of one orphan, in receipt of grants since 1877, was reported. The consideration of the proposed alteration of the by-laws was postponed till the October court.

**LONDON HOSPITAL MEDICAL COLLEGE.**—On Tuesday, the Duke of Cambridge distributed the following prizes to the successful students at this institution:—Entrance science scholarships, £60, Mr. F. J. Smith; Buxton scholarships, £30, Mr. W. R. Hodge; £20, Mr. J. W. Pugh; Letheby prize, £30, Mr. A. J. Richardson; hon. certificate, Mr. F. H. Taylor; scholarship in anatomy, physiology, and chemistry (open to first and second year's students), £25, Mr. F. Hitchens; hon. certificate, Mr. G. H. Ailken; scholarship in human anatomy (open to first year's students), £20, Mr. H. Cropley; hon. certificates, Mr. F. J. Smith, Mr. H. Tonks; scholarships in clinical medicine, £20, Mr. R. F. Fox; hon. certificate, Mr. J. Sinclair; scholarship in clinical surgery, £20, Mr. R. F. Fox; hon. certificate, Mr. J. C. Davies; scholarship in clinical obstetrics (a prize of £15 being awarded by the lecturer on obstetric medicine to the holder of this hon. certificate), £20, Mr. A. J. Richardson; hon. certificate, Mr. R. F. Fox; minor surgery prizes, £15, Mr. J. M. Evans; £15, Mr. J. E. Crisp; £10, Mr. J. Thomas; £10, Mr. F. Hitchens; dissection prizes, £6, Mr. H. Jaboor, junior; £4, Mr. H. Jaboor, senior; osteology prizes, £6, Mr. J. Vincent; £4, Mr. C. T. Samman.

**COMPULSORY NOTIFICATION OF CONTAGIOUS DISEASES BY MEDICAL MEN.**—On July 11th, a meeting was held at the Lecture Hall, Greenwich, to consider the clause in Mr. Hastings' Bill compelling medical men to notify cases of infectious disease in their practice to the sanitary authorities. Dr. Prior Purvis occupied the chair. The following resolutions were unanimously carried:—1st. "That we form ourselves into an association for the simple purpose of resisting the attempts that are being made to compel medical men to notify cases of infectious disease." 2nd. "That we affiliate with the Liverpool association formed for a similar purpose." 3rd. "That Dr. Prior Purvis be elected chairman for the first year, and Dr. Alexander Forsyth hon. secretary and treasurer."

**HOSPITAL SUNDAY.**—The Committee of Distribution of the Metropolitan Hospital Sunday Fund met on Wednesday to apportion to the London hospitals the largest collection yet made in the metropolis. Since the fund was instituted in 1873, the sum of £284,000 has been collected through its agency for the London hospitals, the amounts each year varying from a minimum of £24,905 in 1878 to a maximum of some £33,000 in 1882. Last year the Council received its first legacy of £300, an example which ought to be widely followed by those who desire to leave money to hospitals, because by adopting this course they have an absolute guarantee that their charity will be dispensed in exact proportion to the merits and claims of each institution. Hospital Sunday, which was first established in Birmingham in 1859, did not take root in the metropolis until 1873, notwithstanding the fact that from the end of 1869 until Sir Sydney Waterlow became Lord Mayor, a period of some four years, month after month THE LANCET strongly urged the desirability "of half a dozen secretaries of the leading London hospitals, backed by some of the most influential members of the governing bodies, interviewing the Lord Mayor, and asking him to put himself at the head of the Hospital Sunday organisation." Once started in London, the movement soon spread to all parts of the country, and within the last two years it has crossed the Atlantic and become an American institution. Everywhere Hospital Sunday seems to flourish, and by its means the hospitals of this country have already benefited to an extent which cannot be much less in the aggregate than £1,000,000.

## Medical Appointments.

*Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning at the latest.*

- ANDERSON, JAMES, M.D., C.M.Aber., has been appointed Assistant-Physician to the City of London Hospital for Diseases of the Chest, Victoria-park.
- ANNANDALE, THOMAS, F.R.C.S. Ed., M.R.C.S., has been appointed Consulting Surgeon to the Royal Hospital for Sick Children, Edinburgh, vice Prof. Spence, deceased.
- BRICKWELL, BENJ. ARTHUR, M.R.C.S., L.S.A. Lond., has been re-appointed Medical Officer of Health for the Amersham Union.
- DANCY, HORACE M., M.D. Glas., L.S.A. Lond., has been appointed Medical Officer to the Farnfield District of the Southwell Union.
- GRAHAM, ALBERT W., L.R.C.P., L.S.A. Lond., has been appointed House-Surgeon to the Hobart General Hospital, Tasmania.
- GRIPPER, ARTHUR DOUGLAS, L.R.C.P. Ed., M.R.C.S., has been appointed Medical Officer to the Grassington District of the Skipton Union.
- HARDING, RICHARD, L.R.C.P., L.F.P.S. Glas., has been appointed Medical Officer to the Prestelgne District, Knighton.
- JACKSON, SANDFORD, M.B., has been appointed Assistant House-Surgeon to the Brisbane Hospital, at a salary of £250 per annum, and apartments.
- KEMP, JOHN R., L.R.C.P. Lond., M.R.C.S., has been appointed Clinical Assistant to the Westminster Ophthalmic Hospital.
- KESTVEN, LEIGHTON, M.R.C.S., has been appointed House-Surgeon to the Brisbane Hospital, at a salary of £500 per annum, and residence.
- LIVETT, HENRY WM., L.R.C.P. Ed., M.R.C.S., L.S.A. Lond., has been reappointed Medical Officer of Health for the Wells Urban Sanitary District.
- MARLEY, WM. LANE, M.R.C.S., has been appointed Surgeon to the Port Douglas Hospital, Queensland.
- MARSDEN, THOMAS, M.R.C.S., L.S.A. Lond., has been appointed Medical Officer to the Third District and Workhouse, Bridgewater Union, vice Axford, resigned.
- MORGAN, JOHN H., F.R.C.S., has been appointed Consulting Surgeon to St. George's Dispensary.
- MORTON, CHARLES A., M.R.C.S., L.R.C.P. Lond., has been appointed Senior House-Surgeon to the Stanley Hospital, Liverpool.

RUSSELL, M. W. H., M.R.C.S. & L.S.A.Lond., has been appointed Resident Medical Officer to the Bath Royal United Hospital, vice Pratt, resigned.

SANDERS, JOHN WILLIAM, M.D., has been appointed Resident Medical Officer to the Bethnal-green Infirmary, vice Boyd, resigned.

SAUNDERS, CHAS. EDW., M.D., C.M.Ed., M.R.C.P.Lond., has been reappointed Medical Officer of Health to the Tring Urban Sanitary District.

SHAW, WALTER, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer to the Burghill District, Hereford Union.

WHITE, EDW. ARTHUR, M.D., C.M.Aber., L.S.A.Lond., has been appointed Medical Officer to the Third District of the Malmesbury Union.

WILSON, CHAS. WM., M.B.Durh., M.R.C.S., has been appointed Medical Officer to the Southern District and Workhouse of the Cirencester Union, vice Hodges, resigned.

WOODHEAD, GERMAN SIMS, M.D., C.M., M.R.C.P.Ed., has been appointed Pathologist to the Royal Hospital for Sick Children, Edinburgh, vice Hamilton, resigned.

## Births, Marriages, and Deaths.

### BIRTHS.

BARNES.—On the 16th inst., the wife of R. Barnes, M.D. (of Harley-street), of a daughter (stillborn).

COATS.—On the 14th inst., at Elmbank-crescent, Glasgow, the wife of F. Coats, M.D., of a daughter.

DUNLOP.—On the 10th inst., at St. Helen's, Holywood, co. Down, Ireland, the wife of Archibald Dunlop, M.D., of a daughter.

HEELAS.—On the 9th inst., at Buckhurst, Primrose-hill-road, Hampstead, the wife of James Heelas, M.D., of a daughter.

MUTCH.—On the 7th inst., at Sneinton-road, Nottingham, the wife of F. Robertson Mutch, M.B., C.M.Aberd., of a daughter.

NEILL.—On the 17th inst., at 3, The Terrace, Ryde, Isle of Wight, the wife of Channing Neill, M.D., of a son.

ROBERTSON.—On the 12th inst., at The Friarage, Penrith, the wife of J. D. Robertson, M.D., of a son (stillborn).

SHARPLES.—On the 15th inst., at Wellfield House, Farington, the wife of T. Sharples, Surgeon, of a son.

WOOD.—On the 12th inst., at Lees Lodge, Yalding, Kent, the wife of E. J. Wood, M.B.Cantab., of a daughter.

### MARRIAGES.

ATTLEY—THORNE.—On the 13th inst., at St. Jude's Church, Southsea, Surgeon John Attley, R.N., son of D. Attley, Esq., of Keel Hall, Desert, Cork, to Katie Coppinger, youngest daughter of James Lyon Thorne, R.N., of Somerset House, and granddaughter of the late Captain William Thorne, 3rd Buffs, of Carline, co. Cork.

COLDSTREAM—BROCK.—On the 12th inst., at Hillhead Parish Church, Glasgow, Alexander R. Coldstream, M.D., F.R.C.S.E., of Newington, Edinburgh, to Margaret Mary, second surviving daughter of George Brock, Esq., of Greenland, Thurso.

DAY—O'LEARY.—On April 27th, at the Church of the Garça, Pernambuco, William A. Day, M.R.C.S., to Mary Louisa Charlotte, eldest daughter of the late Daniel O'Leary, of Bath (England).

MACLEOD—MARJORIBANKS.—On the 11th inst., at the Parish Church, Scotby, Carlisle, M. D. Macleod, M.B.Ed., Medical Superintendent of the East Riding Asylum, Beverley, to Daisy, youngest daughter of the late Samuel Marjoribanks.

MILLER—WHITE.—On the 11th inst., at Trinity, by the Rev. D. Kilpatrick, of Newhaven, G. Miller, M.D., of 9, Rankellor-street, Edinburgh, to Margaret, eldest daughter of the late John White, Esq., of Garlton, East Lothian.

WRIGHT—BATEMAN.—On the 12th inst., at St. Saviour's, Aberdeen-park, N., Christopher St. John Wright, M.B., M.R.C.S., of Priors Marston, Warwickshire, to Agnes Louisa, daughter of the late Henry Bateman, F.R.C.S., of Canonbury-lane, N.

### DEATHS.

COTTON.—On the 12th inst., at the Royal Naval Hospital, Stonehouse, Inspector-General John Cotton, M.D.

DICKIE.—On the 15th inst., at Albion-terrace, Aberdeen, George Dickie, M.D., F.R.S., Emeritus Professor of Botany.

DODGSON.—On the 10th inst., at Derwent House, Cockermouth, Henry Dodgson, M.D.Edin., L.S.A.Lond., L.R.C.S., F.R.A.S., F.M.S., aged 49.

HARVEY.—On the 16th inst., at his residence, St. Mark's-terrace, Lincoln, Richard Sutton Harvey, J.P. & F.R.C.S., aged 79.

MILNER.—On the 11th inst., at The Crescent, Salford, Ralph Milner, M.R.C.S., L.S.A.Lond., aged 64.

MOFFAT.—On the 16th inst., Thomas Barbour Moffat, M.D. &c., of Hawarden, Flintshire, where he had carried on his profession for 45 years, aged 69.

SILVER.—On the 16th inst., at his residence, Upper Tooting, Alexander Silver, M.A., M.D., M.R.C.P., of 2, Stafford street, Old Bond-street, Physician to Charing-cross Hospital, aged 41. (Interment will take place at Brompton Cemetery at 1 o'clock on Saturday.)

WIGHT.—On the 28th ult., at St. John's, Canada East, near Montreal, Robert Wight, M.D., eldest son of the late Robert Wight, Esq., Colonial Bank, London, in his 60th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## ROYAL COLLEGE OF SURGEONS OF ENGLAND.

REPORT from the Board and the Court of Examiners of the number of candidates who have presented themselves for the primary and pass examinations for the diploma of Member of the College during the collegiate year 1881-82, showing the number who have passed and have been rejected from each Medical School during that period.

### PRIMARY EXAMINATIONS.

Medical Schools.	Totals.	Number passed.	Number rejected.
St. Bartholomew's	158.50	117.50	41
University College	111	69	42
Guy's	106.50	71.50	35
King's College	63.50	36	27.50
London	57	44.50	12.50
St. Thomas's	50.50	36	14.50
St. George's	48	38	10
Middlesex	40	26	14
Charing-cross	34.83	24.50	10.3
St. Mary's	22.3	14	8.3
Westminster	22	14	8
Manchester	67	47.50	19.50
Cambridge	32.3	24.50	7.83
Liverpool	30.50	19	11.50
Leeds	26.50	18	8.50
Birmingham	21	16	5
Newcastle-on-Tyne	19.50	15.50	4
Bristol	15.50	12.50	3
Sheffield	6.3	2.3	4

## Notes, Short Comments, and Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*We cannot prescribe, or recommend practitioners.*

*Local papers containing reports or news-paragraphs should be marked.*

*All communications relating to the editorial business of the journal must be addressed "To the Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

## FIRST YEAR'S EXAMINATION IN ELEMENTARY ANATOMY AND PHYSIOLOGY.

WE have received a long disputations rejoinder from Mr. Butlin on our remarks last week. As no useful purpose can be served by the publication of statement and counter-statement, no matter how vigorous the language or how complacent the tone, it is not necessary to publish the correspondence. It may be enough to remark that it is our misfortune to be completely and hopelessly at variance with Mr. Butlin's opinions of the nature, purport, and value of first year's examinations in elementary anatomy and physiology when conducted by teachers at the medical schools.

*Enquirers might consult Dr. Hardwicke's "Medical Education and Practice in all Parts of the World."*

*Mr. Phillips Hills is thanked.*

## "INVETERATE BOILS."

*To the Editor of THE LANCET.*

SIR,—In your last issue "Subscriber" asks for suggestions as to the treatment of a case of inveterate boils. In reply, I must refer him to what I have said on this subject in THE LANCET for 1874, vol. i., and for 1869, vol. ii. Let him carefully follow the instructions there given as to the insertion of the carbolic acid into the formed boil through its one or several openings; let him discard all ideas as to boils being a means of throwing out of the system morbid matters; and let him act upon the conviction that boils are local, parasitic, and contagious. Let the patient take a daily morning bath; let him avoid any undue pressure upon or injury to the skin; and let especial care be taken to destroy each incipient boil in its earliest stage by any good strong caustic acid: nitrate of mercury, nitric acid, strong solution of carbolic acid, or nitrate of silver.

But as boils, like other parasitic diseases, chiefly occur where there is defective hygiene or deficient health, let the patient also live carefully and temperately, and be treated with any general remedial measures which may appear appropriate. A somewhat extended experience of such cases induces me to believe that by such measures "Subscriber" will not be long in securing a cure of his case.

I am, Sir, yours obediently,

Norwich, July 18th, 1882. PETER EADE, M.D., F.R.C.P.

*To the Editor of THE LANCET.*

SIR,—In last week's LANCET "Subscriber" wishes hints regarding the treatment of the above. I have found that tincture of arnica given in fifteen-drop doses in a little water every two hours for twenty-four hours, and afterwards every six hours for a week, entirely removes attacks of boils. If "Subscriber," after a fair trial, would give the result in THE LANCET I would feel obliged.—I am, Sir, yours, &c.,

July 17th, 1882

F.R.C.S.

## EXAMINATIONS AT THE ROYAL COLLEGE OF SURGEONS.

At the written portion of the Pass Examinations for the diploma of membership of the Royal College of Surgeons the following were the questions on Surgical Anatomy and the Principles and Practice of Surgery submitted to the 230 candidates on the 14th inst., when they were required to answer at least four, including one of the first two, out of the six questions, from 1.30 to 4.30 P.M. :—

1. What structures of surgical importance pass through the parotid gland? What is their relative situation, and what are the relations of the gland itself?
2. Describe the parts composing the ankle-joint, giving the forms of the articular surfaces, the attachments of the ligaments, the movements of the joint; and mention, in order, the structures in direct relation with the joint.
3. By what symptoms would you be led to infer the existence of a loose body in a joint, say the knee? How would you treat such a case?
4. Give the clinical symptoms which mark the progress of caries of the vertebral column proceeding to a fatal termination; and indicate the treatment you think proper in the several stages of this disorder.
5. A man is stabbed through the anterior fold of the axilla, and serious hæmorrhage occurs. What vessels may have been wounded, and what treatment would you adopt?
6. Describe syphilitic lritis, detailing the symptoms and treatment.

The following were the questions on Midwifery and the Diseases of Women and Children submitted to the candidates the following day, the 15th inst., when they were required to answer three out of the four questions, between 12.30 and 2 P.M. :—

1. What are the causes of secondary hæmorrhage after labour? How would you treat it?
2. In what circumstances, and how, would you induce labour at the seventh month?
3. How would you estimate the size and shape of a supposed contracted pelvis?
4. How would you differentiate the following conditions :—Pregnancy at the sixth month, an ovarian tumour reaching to the umbilicus, a uterine fibroid reaching to the umbilicus, and effusion of blood reaching to the umbilicus?

The following were the questions on the Principles and Practice of Medicine, to be answered the same day, from 2.30 to 4.30 P.M., when they were required to answer three out of the four questions, including question 4.

1. What are the consequences, local and general, and what the diagnostic signs, of the following varieties of heart disease :—(a) Obstruction at aortic orifice; (b) incompetence of aortic valve; (c) obstruction at mitral orifice; (d) incompetence of mitral valve.
2. What are the various causes of obstruction of the œsophagus? and how would you distinguish them clinically from one another?
3. Discuss the morbid anatomy and symptoms of the different kinds of goitre, and their relations to other morbid states.
4. Describe the composition, dose, and uses of the following preparations :—Liquor arsenicalis; liq. bismuthi et ammoniæ citratis; liq. hydrargyri perchloridi; liq. ferri persulphatis; pilula phosphori; pil. plumbi cum opio; pil. quinae; pil. saponis composita; pulvis cretæ aromaticus cum opio; pulv. ipecacuanhæ compositus; pulv. jalapæ compositus; pulv. kino compositus; vinum antimonialle; vin. colchici; vin. ipecacuanhæ; vin. quinae.

*Mr. Charles Lunn.*—The insertion of the letter would open a discussion for which at present we have not space.

## CONVULSIONS IN CHILDREN.

*To the Editor of THE LANCET.*

SIR,—In Dr. Eustace Smith's paper on the above subject (see THE LANCET of the 15th inst.) I am surprised to find that he advocates the use of the warm bath in doubtful cases as to the exciting cause of the seizure. Allow me to point out that the bath is a most dangerous experiment under such circumstances, and I am sure that the writer of the article will be ready to admit that it is not to be recklessly resorted to when it is remembered that overfeeding is a very common source of mischief in the case of hand-fed infants by ignorant mothers and nurses; that an overloaded stomach frequently causes convulsions; and that a bath under such conditions would most assuredly intensify the mischief. I trust that Dr. Eustace Smith will see fit to modify his recommendation of the bath in convulsive seizures, as young practitioners might be misled by the unqualified statement of such an authority.

I am, Sir, yours obediently,  
M. A. B.

July 17th, 1882.

## VACHER'S FORCEPS.

*To the Editor of THE LANCET.*

SIR,—I should feel much obliged if some of your correspondents would give their experience in the use of Vacher's holding midwifery forceps, or Draper's modification of the same instrument. I am anxious to know the class of cases for which it is suitable, and also the limits to its use as regards the stage of labour and state of the parts.

I am, Sir, yours truly,

London, July 11th, 1882.

J. BENSON COOKE.

## DISPENSING IN VILLAGE PRACTICES

*Mr. Kenneth W. Millican, B.A. Cambridge, M.R.C.S.*—We quite agree with our correspondent that in such circumstances it would be almost cruel for the practitioner not to dispense his medicines. Much has to be done yet, by accommodation on the part of chemists, before medical men can abandon dispensing altogether. Meantime, when there is so much convenience in it, it cannot be degrading, though it may be irksome. We have received a large number of letters on this subject, but our space will not permit of their publication.

## UNQUALIFIED ASSISTANTS IN BIRMINGHAM.

*The Daily Mail* has a short article, but one much to the point, on the number of unqualified assistants in Birmingham and the countenance they receive from properly qualified medical men. After the recent decision in the case of *Mr. Murdoch*, medical men will do well to supervise very closely their unqualified assistants.

## THE CLIMATE OF DENVER.

*To the Editor of THE LANCET.*

SIR,—Nearly all places on the North American Continent, those excepted near the coasts and far to the south, have a far larger range of temperature than we are accustomed to. Denver is certainly no exception to this rule; its mean temperature is 50°, almost the same as that of London and Devonshire; and its rainfall is 24·50 inches, much less than that of most English towns, though not more than that of a few places in our Eastern Counties. The distribution of rain is decidedly more irregular than with us, our normal rainfall in the Midland and South-eastern Counties averaging from two to three inches every week through the year. At Denver the winter is extremely dry, the monthly rainfall ranging from one-tenth of an inch to two inches, while in the summer from four to even ten inches may fall in a month. Every meteorologist, however, knows that the rainfall varies more in different seasons than any other meteorological element. The temperature at Denver is as follows. I give the mean, the maximum, and the minimum of every month, and the ranges:—

Month.	Mean.	Max.	Min.	Range.
January.....	28·3	59	2	57
February.....	37·7	66	7	59
March.....	34·4	70	3	67
April.....	49·3	82	4	78
May.....	57·1	85	32	53
June.....	65·8	97	38	59
July.....	68·1	96	53	42
August.....	68·9	96	50	46
September.....	61·7	92	32	60
October.....	54·1	84	27	57
November.....	37·3	75	5	70
December.....	37·8	66	—3	69

In other words, the five cold months are decidedly colder than with us; the five warm months are as decidedly warmer; while April and October are not very different from the same months in Devonshire in mean temperature, though the extremes are far greater.

The air at Denver is undoubtedly dry, and the amount of sunshine large. Persons going from the damper and hotter southern States find the climate of Denver bracing and exhilarating, and many people for a time like it. Two very distinguished Englishmen who visited it some years ago loudly complained of the enormous range of temperature, and one of them, a scholar of European reputation, spoke of the days as feeling intensely hot and the nights as being unbearably cold. This would be no oratorical exaggeration, for a diurnal range of over fifty degrees is not unknown, and the midday sun in that dry inland climate and comparatively low latitude is rather too powerful to suit an Englishman.

I am, Sir, yours faithfully,  
Wimborne, July, 1882.

ALFRED J. H. CRESPI.

*Enquirer.*—It is against our rule.

THE letter of *M. O. H. (Mansfield)* would have more weight with the name attached.

*Mr. T. S. Clayton.*—5, York-buildings, Duke-street, Adelphi, W.C.

## PUERPERAL EPILEPTIC CONVULSIONS.

*To the Editor of THE LANCET.*

SIR,—I am very glad to see by *THE LANCET* of April 8th and 15th that Messrs. Lucas and Beatty have been successful in treating puerperal convulsions by the hypodermic injection of morphia. Since publishing my last cases I have to add five additional ones, in all of which this method has been tried with excellent results. These and the cases reported by Messrs. Lucas and Beatty, together with sixteen I collected previously, make twenty-six in all. In no single case has the morphia yet failed. Of course a much larger number of cases will be required to settle the exact value of this procedure as to its success and its possible danger. In the meanwhile, remembering that Churchill's statistics give a mortality of one in every four and a half cases of puerperal epileptic convulsions, I think that a record of twenty-six cases, many of them of a very severe character, in every one of which the fits were stopped and the patients recovered, is sufficiently encouraging to warrant the giving of this treatment a fair trial.—I am, Sir, yours faithfully,

Geelong, Victoria, June 5th, 1882.

S. MABERLY SMITH.

## ELEPHANTIASIS SCROTI.

WE recently referred to a paper on Elephantiasis of the Scrotum, by Dr. G. A. Turner, which appeared in the *Glasgow Medical Journal*. We are requested by Dr. Turner to correct two inaccuracies in regard to Dr. G. V. MacDonagh which inadvertently crept into the paper in question. It appears that Dr. MacDonagh did not witness O'Farroll's operation, and that he did not obtain a hint for the design of his clamp from Drutt's *Vade Mecum*, in the editions of which up to the ninth no mention of it is made. It was stated that in Dr. MacDonagh's second operation one testicle was removed; the fact is, both testicles were preserved.

*C. D. A.*—The information with regard to dairies is, we believe, furnished by the dairy keepers, and they should apply to be put on the register. The premises are then inspected. The local authority attend to the expenses. A short time ago, in the House of Commons, Mr. Mundella stated that a Bill was about to be introduced to regulate dairies and their inspection.

THE request of *Drs. Bernard and Donaldson* shall have attention.

*Dr. Caddy.*—We do not see any novelty in the apparatus.

## ACUTE ALCOHOLIC DELIRIUM.

*To the Editor of THE LANCET.*

SIR,—In reference to the case of alcoholic delirium mistaken for hydrophobia, which is referred to by your Paris correspondent in *THE LANCET* for July 8th, I may relate a somewhat similar case, which occurred at the Tottenham Training Hospital a few weeks ago.

The patient was drinking at a neighbouring public-house on Whit Monday when the symptoms occurred. According to all accounts, he had not drunk more than one or two pints of ale when the attack came on. He became suddenly maniacal, bit off and ate part of a glass tumbler, and attacked his wife and others who were near. He was brought to the hospital strapped on a stretcher by a policeman, and then exhibited tendencies to injure himself and those around him, repeatedly dashing his head violently against the stretcher, and snapping at fingers and hands which came within reach. A medicine glass containing some chloral and bromide of potassium was offered him, but he seized the glass with his teeth, bit off a considerable piece, and then proceeded to munch and swallow it. A hypodermic injection of about half a grain of hydrochlorate of morphia was then administered, and the delirium subsided in about half an hour. About two hours after his admission he went home, walking steadily, and in his right mind, and, as far as is known, has suffered no injurious effects from his novel meal. His wife stated that drinking had produced a similar effect on him at previous times.

Are we to look on such a case as one of idiosyncrasy with respect to alcohol, or is it more likely that the effects were due to some other poison adulterating the ale?—I am, Sir, yours faithfully,  
Tottenham, July 8th, 1882.

SIDNEY DAVIES, B.A. Oxon., &c.

*J. C. M.*—The principle is well understood that the obstetric fee only covers the attendance at the time of confinement and for a reasonable period after. It certainly is not intended to cover attendance during pregnancy, nor visits paid after ten or twelve days from the time of delivery. A little explanation will probably satisfy our correspondent's patient. The charges appear quite reasonable.

*M. C.*—Both the English and Irish Registration Acts contain a compulsory clause under which it is incumbent upon every registered medical practitioner to furnish, for registration purposes, a medical certificate stating to the best of his knowledge and belief the cause of the death of each patient who has been attended by him during such patient's illness.

*Mr. Samuel Coates.*—The conduct does not seem very kind or professional.

## THE CAUSE OR CAUSES OF ACUTE TONSILLITIS.

*To the Editor of THE LANCET.*

SIR,—Having been myself in times past a frequent sufferer from quinsy, and having been careful always to make inquiries of those who have come under my care as to the cause or causes which have brought it about, I think my views are entitled to some amount of consideration. First, then, I would say that it is a disease which occurs but seldom after twenty-one; that it is essentially adynamic in type; and that it is always the result of an exhausted nervous or muscular system. Exposure to cold has apparently little or nothing to do with its causation, for it is a positive fact that wrapping up the throat in no way tends to prevent it. Defective ventilation may have something to do with its causation, but still I think it will be found to exist almost, if not quite, as much in well-as in ill-ventilated houses. In my own case I used to notice, and I have been able to extract the same information in nearly every other instance, that there was over-exertion and often great irregularity in meals prior to the attack. In fact, a week of really hard work and irregular meals would be sufficient even now to knock me over with quinsy. I trust these few remarks will give rise to a little discussion, as I am sure that the pathology of quinsy is but little understood.

I am, Sir, your obedient servant,

Kingston-on-Thames, July, 1882.

F. P. ATKINSON, M.D.

**ERRATUM.**—In Mr. Hodges's letter on Anæsthetics, published last week, page 80, instead of "we calculate etherisation costs the infirmary now 3s. 4d. less than formerly," read "three-fourths less," &c.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.  
QUEKETT MICROSCOPICAL CLUB.—8 P.M. Annual General Meeting.

### Saturday, July 29.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

## SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year.....£1 12 6 | Six Months .....£0 16 8  
TO CHINA AND INDIA ..... One Year, 1 16 10  
TO THE COLONIES AND UNITED STATES.. Ditto, 1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 67, Rue Caumartin, Paris.

# Arris and Gale Lectures

ON THE

## RELATION OF EXPERIMENTAL PHYSIOLOGY TO PRACTICAL MEDICINE.

*Delivered at the Royal College of Surgeons, June, 1882,*

By G. F. YEO, F.R.C.S.,

PROFESSOR OF PHYSIOLOGY IN KING'S COLLEGE.

### LECTURE III. — PART I.

#### THE DEPENDENCE OF THE MODERN RATIONAL METHODS OF TREATMENT UPON A KNOWLEDGE OF PHYSIOLOGY.

MR. VICE-PRESIDENT AND GENTLEMEN, — Were I to attempt to explain in all its completeness the relationship borne by experimental physiology to the rational practice of medicine, it would be necessary to devote several lectures to the subject. In to-day's lecture I must therefore restrict my observations to that part of the question which is just now most nearly before my mind—namely, What has vivisection done towards the advancement of modern practical medicine? Over and over again we have been challenged by the opponents of science to give "one conclusive example where experiment has been of direct use to practical medicine." To anyone familiar with the history of scientific medicine there can be no difficulty in finding numerous such instances, and, as a matter of fact, many examples have from time to time been given by various writers; but to make these cases satisfactory and conclusive to persons who know but little, and do not care to know more, of the true bearings of the question, is a very difficult matter. Such a test is totally wrong and misleading when applied to the utility of experiment on the lower animals. The matter must be viewed from a wider standpoint than that embracing only single instances of direct benefits accruing from specific experiments.

The primary object of experimental research is to advance physiology—the science which teaches us the uses of the various organs and textures of the body in the normal state, and how the working of the animal economy is carried on in health. The value of physiology depends on the knowledge it gives us of the normal operations of the body, and not on the few cases in which certain experiments happen to aid us in understanding disease, and thus directly promote the practice of the healing art. Our argument is rather this: Physiology is the foundation of both pathology and therapeutics, which together make up medicine; and therefore rational medicine depends directly upon physiology for its strong growth and genuine progress.

Now physiology cannot advance without vivisection; experiment on living animals is as essential to its progress (though far less general in application) as is dissection for the study of anatomy. Therefore experimental research, including that carried out on living animals, is as necessary for the progress of the practice of medicine as is experimental research in any other science for its advancement and application to daily life. The immediate object of physiological experiment is, then, not to make out new practical methods of treating disease, but rather to attain to a more complete and sound understanding of those general laws which govern the actions of the living body in health—laws which must ever form the only firm basis of the knowledge of disease, and the only sure guide to judicious modes of treatment.

The rational practice of physic, as it is carried on in the present day, is in a great measure the outgrowth of a slowly growing physiological science, upon which it depends, and from which it cannot be separated. There is hardly a thought that can strike a practitioner that does not in some way depend upon physiological facts which have been elicited by experimental research. I do not mean to state that the accurate and painstaking observation of clinical facts and post-mortem appearances has not done much—probably more than anything else—to bring our medical knowledge to its present standpoint; but I contend that clinical observation and post-mortem experience without physiological research would never have been able to advance

medicine to the position it holds in modern times; and, on the other hand, I believe that physiological study, even unaided, could arrive at a rational system of treatment. No doubt both clinical study and pathological observation have not only helped practical medicine onward, but they have also greatly contributed to the progress of physiology itself. In fact, I find it impossible to separate exact clinical and pathological work from scientific research of a purely physiological nature. Is not all treatment more or less experiment? And is not this particularly true of purely empirical treatment? Nowadays, where is the pathological laboratory in which a mere record of post-mortem changes in the human subject is not aided by experimental inquiry into pathological changes in the lower animals?

In assigning to each department of medical study its due meed of credit, their relative ages must be borne in mind. It has been asserted that all the improvements brought about by experimental research would have been introduced with equal certainty had experiment on living animals never been attempted. Observation, experience, and thought would have attained all the results we now enjoy. Possibly so; but when? Clinical observation can be traced back some three or four thousand years, and even then it started with a rich legacy of traditional knowledge. Experimental physiology as a science was only born about a hundred years ago. If we compare the progress made by medicine during the last hundred years with that of the previous thousand years, we shall be able to judge of the relative rates of progress of the two systems of working. The difference seems to me to lie in the fact that unaided clinical observation—that is, practically the empiric method—goes the wrong way about arriving at a conclusion. It says, try this or that or the other remedy, and note which is successful. This is like a boy who will not systematically work out his sum in long division, but prefers to arrive at the quotient by guessing probable numbers one after the other, and multiplies them to see which is the right one; he may, after much trouble, by chance hit upon the correct answer, but he more commonly fails; and most probably the boy who works out his sum in the straightforward way will far sooner arrive at the desired result. Physiology moves onwards by means of accumulating and arranging facts which have borne the test of experiment. Empiricism accumulates observations which, without further test, are used to formulate theories that, as likely as not, are unfounded, and are as apt to mislead as to advance medical knowledge. When asked to give an example of the utility of experimental physiology in the treatment of disease, I feel inclined to answer with another question: Is there one reliable system of diagnosis or one mode of treatment now in use which has not been modified or improved, if not directly suggested, by physiological knowledge? And I must certainly confess that I know none. Before attempting to bring forward single cases as instances where certain experiments have been of direct use to medical and surgical practice, I shall examine the question from the opposite standpoint, by taking some simple case of every-day occurrence, and glancing at its routine examination and treatment. We can then see to what extent vivisection influences the practitioner in the details of his daily work. We may safely take a case at random; one not associated very closely in our minds with any brilliant experimentation will perhaps be the best. The following case, which I happen to have seen recently, will do as well as any other.

Not long since I found a policeman examining a poor woman who was said to have had a "stroke." She lay speechless and motionless on a door-step; she showed no signs of convulsions, no stertorous breathing, no frothing at the mouth. So the policeman hesitated to make a diagnosis, thinking, no doubt, that other causes besides a "stroke" might give rise to such a want of muscular irritability. Gently shaking her had no effect, but on his applying some form of stimulus to the finger she showed signs of returning consciousness, and the left leg and arm moved slightly. The right eye remained partly open, the other was closed; when the eyelid was raised, so as to expose the pupil to the sun-shine, some movement of the muscles of expression was observable, but only on the left half of the face, to which side the mouth was slightly drawn. This became more obvious when some drops of cold water were thrown at her. The pulsation of the temporal artery was visible. Putting my ear to the top of her chest I found the heart beating violently, and heard a prolonged blowing noise instead of the sharp clear tone of the second heart-sound.

D

Without much effort my thoughts had passed from the pulsating temporal artery to the heart, and from the imperfect aortic valves to the middle cerebral artery, where I fancied an embolus must be impacted. I told the policeman the woman had better be taken to a hospital, which was done accordingly.

How was it that I was able confidently to advise the policeman about this poor woman, though he was no doubt very experienced in these sort of cases? What aid did experimental inquiry give me in arriving at my conclusion?

Well, in the first place, I knew that the paralysis was restricted to voluntary movements, without the motions belonging to organic life being in the least interfered with. Vivisections of the earliest times informed me that this was quite possible as a result of some injury of the nerve centres, and experiments of more recent date enabled me to exclude a large part of these centres from being the seat of the lesion. That there was no local injury of the spinal cord in the dorsal region I knew, both from the loss of consciousness and from the fact that the reflex action of the lower limbs was not intensified, and vivisections informed me they would have become so had this been the case. I could see by the movement of the left leg that only one side of the body was paralysed; and then the look of the face distinctly showed that part of the seventh cranial nerve, which Charles Bell's vivisections taught me to know to be motor in function, was paralysed. This fact, together with the ready reflex action of the eyes and the sound side of the face, which I knew by vivisection required unimpaired sensory nerves, showed me that it could not be a case of profound toxæmia such as the policeman supposed to be possible. I knew by vivisections performed by many English physicians and physiologists, some of whom are still among us, that the second heart sound depended on a certain action of the aortic valves. Not hearing the familiar sound, I concluded that the aortic valves must be diseased. Experiments on living animals concerning coagulation of the blood within the vessels informed me that when the lining coat of a bloodvessel, or the heart, is diseased little clots are often formed at the diseased or injured part. I knew, further, from Virchow's classical experiments on living animals, that emboli introduced into the arterial blood-current often become impacted in the middle cerebral artery, and that the embolic blocking of a brain-artery, by shutting off the blood from the area it supplied, caused a sudden arrest of function of the part. Although the nerves going to the various paralysed muscles arose from very different regions of the cord and brain, I know by vivisections that there is a part of the cortex of the brain the injury of which would cause them all to be powerless. Clinical observation and pathological anatomy would have informed me that it was probably a brain lesion; but had it not been for the light thrown by vivisection on the few facts I was able thus hurriedly to observe I should not have been much wiser than any other bystander, and could only have agreed with them that it was a "stroke" of paralysis.

Now let us consider a surgical case. The other day I mentioned some of the old methods of operation, when buttons of virriol, caustics, steel compresses, boiling oil, hot irons, a copious receptacle for catching the blood, and elaborate machines, such as those on the table, were among the apparatus the surgeon had to prepare for operation.

Let us now turn to a modern operation, and let us consider whether our present *modus operandi* is influenced by the light which experimental inquiry has shed on physiology during the last century. I shall not attempt to recount any one of the numerous cases which the surgeon now approaches with perfect confidence of undoubted success, although a comparatively short time back they would have been looked upon as completely beyond his reach. Many such cases, which formerly would have led either to certain death, enduring misery, or life-long inconvenience, must occur to the minds of all here. Let us take a case of disease or injury requiring the amputation of a portion of an extremity. In the first place the patient is made quite insensible to pain by the administration of chloroform, or some such drug; not only is he insensible to pain, but also unconscious to all that he formerly would have been obliged to see and hear, by no means the least painful part of the operation. With regard to the use of anaesthetics, I shall not delay, for vivisection cannot claim to be the sole means of introducing this great boon to modern surgery, although experiment on living animals played a most prominent part both in their

discovery and their introduction into common use in this country, as has been frequently pointed out.

The next step in the operation is to make the part bloodless. This can be done in the following way:—By holding up the limb for some time to facilitate the flow of blood from the veins, and thus to reduce the blood pressure within these vessels, by which means the local vaso-motor mechanisms are brought into play with considerable force, so as to reduce the quantity of blood in the limb, allowing only a limited flow to continue. Then Esmarch's elastic bandage may be applied, to further empty the minute bloodvessels. By this means the textures to be cut into may be made to remain, during the active part of the operation, as bloodless as those of a corpse. The advantage of having no dread of hæmorrhage to induce haste, no blood to impede the view, or render the instruments difficult to handle, can hardly be over-estimated. So that, even apart from the all-important point of preventing the weakly patient losing blood, this bloodless surgery must be regarded as one of the most important improvements in modern methods. And how far may it be traced to vivisection? We know that the contractility of the bloodvessels, and the high pressure of the blood in the arteries, as well as the motions of the heart and the course of the blood, were demonstrated by this means, and is not this the key of the whole matter? But further, were we not familiar by vivisections, and by the removal of tissues from the bodies of recently killed animals, with the fact that the textures can retain their life and function for a considerable period after their normal circulation has ceased, who would have dared to suggest that the entire limb of a living man should be deprived of its blood during the time occupied by a tedious operation?

Then, with regard to the means of permanently arresting the escape of blood from the wounded vessels. We have no longer a receptacle for blood; indeed, the handful of sawdust on the floor that was fashionable when I began medicine is no longer used. John Bell, after giving a graphic and fearful account of the terrors of hæmorrhage, says, "Is not this fear of hæmorrhage always uppermost in the mind of the young surgeon? Were this one danger removed, would he not go forward in his profession almost without fear?" I do not think this fear ever crosses the mind of the young surgeon now, so rare are deaths from external hæmorrhage. I have never seen one death from such loss of blood in the twenty years that have passed since I first commenced to study medicine. Why has the dread of bleeding ceased to chill the heart of the surgeon when entering on an operation? Vivisection has not done all, but it has done much to help us to attain to this degree of excellence in our present methods.

The use of the ligature can be traced so far back in the history of medicine that it is impossible to say whether it was first used upon man or animals. Very definite accounts of it occur in the writings of the Arabians of the tenth or twelfth century. Although its value, or rather its great convenience, in military surgery was recognised and extolled by Ambrose Paré, the inestimable value of the ligature remained unknown in general practice for nearly a hundred years after his time. This was, no doubt, partly on account of the fact that experiment was not used to test its efficacy and mode of action until comparatively recently. By vivisections the chief errors in its application were by slow degrees removed, and now we rest almost exclusively on the improved method of tying arteries as the means of arresting the flow of blood from a recent wound. First of all the nerves used to be included in the ligature. Vivisection showed the folly of thus attempting to confine the animal spirits, or nervous fluid, and practice proved that thus tying the nerves always caused excruciating agony, and often gave rise to fatal spasms (tetanus), which made ligature to be dreaded even by its warmest advocates. In the second place the wide ligatures which were made of soft material and lightly tied over corks, &c., often failed to check the bleeding. Dr. John Thomson, of Edinburgh, was among the first who made experiments on this subject, and I believe much of the credit given to Jones really belongs to him. Following the precepts taught by Thomson, Jones also made numerous experiments on animals. He found that a hard thin ligature applied so as to cut the elastic inner coats and leave the tough outer wall of the vessel uninjured, was much more surely followed by a deposit of "coagulable lymph," and by more satisfactory occlusion of the vessel than when one or several soft bands were tied lightly on it. This fact hardly gained the

universal and complete confidence of surgeons until further vivisections performed by Lister, Brücke, and others, showed that the smooth lining of the vessel was the chief factor in preventing coagulation, and that intravascular clots are formed most readily when the lining of the vessel was injured and the blood ceased to move. Instead of timidly tying a loose knot for fear of injuring the vessel, the surgeon now ties a firm ligature so as to rupture its lining coat, or at least to apply sufficient pressure to cut off its nutrition and thus cause its death in order to make a starting-point for the coagulation which must occur to secure its permanent closure.

Another great objection to the old ligatures was the delay they caused in coming away. This wearied the surgeon and exhausted the patient. The ligature was sometimes pulled away before its time, and this often gave rise to the much-dreaded secondary hæmorrhage. In counselling that the ligature be left alone, Petit adds the remark, as a kind of consolation, that he finds them generally to come away of themselves in about two or three months. Of this sort of annoyance we hear nothing now. Experiment on the lower animals has taught us the existence of the lymphatics and their absorbing power. Experiments upon living animals has shown us that this power of absorbing extends to such things as catgut, a material readily made into strong cords. Properly prepared catgut is therefore almost universally used as a ligature, the ends are cut off short, and the knot is left to be absorbed and never once thought of again.

And, lastly, the edges of the wound are brought together with stitches of silver wire, silk, catgut, horsehair, according to whether much or little traction or more or less coaptation is demanded. Undue tension, compression, gaping, and irregularity of the wounded part, are all avoided; a means of exit for serous oozing, &c., is provided by non-irritating drainage-tubes. The antiseptic dressings are applied carefully and exactly. Large tents, dossils of lint, rude compresses are not thought of. The aseptic wound heals without swelling or inflammation. No throbbing disturbs the patient's rest. No drop of pus comes from the cut surface. Fever, tetanus, pyæmia, second hæmorrhage, as well as the old dread of the bleeding during the operation, are all nearly forgotten.

To the minds of the surgeons of the last century such a method of operation and such a mode of healing would probably suggest the longed-for magic remedies by means of which many hoped to replace the cauteries, caustics, compresses, and filthy dressings with which they strove to heal the open wounds of their exhausted and cachectic patients.

## THE RIDER'S SPRAIN.

By HENRY MORRIS, M.A., F.R.C.S.,

SURGEON TO, AND LECTURER ON SURGERY AT, THE MIDDLESEX HOSPITAL.

A GOOD many of our national sports and amusements are known to give rise to certain accidents and particular morbid changes. Thus, "camping out" occasionally provokes an enlargement of the bursa over the trochanter major, owing to the hardness of the ground upon which persons who go in for this luxury sometimes have to sleep. Rinking has frequently led to Pott's and Colles' fractures. Bicycling has been accused of inducing hernia in its devotees, as rowing has heart disease. Lawn tennis leads frequently to sprain of the knee, or of one of the muscles of the calf. Fractured clavicles and other accidents even of a fatal character are unfortunately too frequent in the hunting-field. I have, however, met with two classes of cases, neither of which are sufficiently well recognised at present—these I may call for the sake of convenience "the lawn tennis arm" and "the rider's thigh." The former is a sprain of the pronator radii teres muscle, and the latter of the adductor longus.

The lawn tennis arm is the result, I believe, of the frequent back stroke, whereby the forearm is brought into rapid and forcible pronation. The condition is slight swelling with tenderness on firm pressure along the course of the pronator, and pain in bringing the muscle into action, but as a rule not otherwise. I have of late seen three such cases, and one gentleman said he had known of several lawn tennis players affected in the same way. The symptoms soon disappear if

the movements of pronation and supination are restricted for a few weeks, and the forearm is enveloped in an elastic bandage or a firm elastic webbing.

The rider's thigh or sprain occurs very frequently; so frequently, indeed, in a mild form that the surgical instrument maker is applied to for some remedial support, though the injury is not thought severe enough to consult the surgeon about it. It is caused generally by the horseman suddenly making a strong grip owing to his horse rearing, shying, slipping, or unexpectedly taking a jump. In this way the adductors are sharply and forcibly brought into action; and some of the fibres of one of them, generally the adductor longus, yield at a short distance from their origin. The pain at the time of the injury is often very trivial, and not sufficient to cause the horseman to dismount; but subsequently more pain is felt in walking; rather severe pain attends the act of mounting, and still more severe, sometimes described as unbearable, pain is excited by gripping the horse. The area of pain is confined to the upper and inner side of the thigh, close to the origin of the adductors, and firm pressure in this part increases the intensity of the pain. Mr. Hawksley the well-known instrument maker of Oxford-street, tells me that during the last twelve years he has seen as many as seventy-five such cases, and as many as ten during the last winter. The accident generally happens to hunting men, is more frequent in tall men, and affects the right thigh more often than the left. For these mild cases Mr. Hawksley makes a long web or leather strap, from two to three inches broad, sometimes padded to localise the pressure. This strap is passed round the thigh and pelvis, like a spica or figure-of-8 bandage, on the outside of the breeches, and is firmly fastened in front. The action of this strap is immediate, as the man can at once firmly grip his horse. Often the huntsman rides to the meet with the strap put on loosely and tightens it up when the hounds get away. In more severe cases the surgeon is consulted, blood is effused, and, if in a large quantity, passes through the saphenous opening and the other numerous apertures in the fascia lata for vessels and nerves, and is thus extravasated beneath the superficial fascia of the thigh, groin, and scrotum; or, perhaps, the fascia, which is thinner over the adductor muscles than elsewhere, is itself ruptured. From these more severe sprains many men lose a season's hunting, but they are as a rule able to ride again after a period of rest and freedom from horse exercise.

I will give briefly the notes of two very severe cases of rider's sprain which during last autumn came under my notice. In Case 1 the whole of the effused blood was not absorbed, but became in part organised into a firm fibrous mass, almost as hard as bone. For this reason it is specially interesting, as it amplifies the truth of M. Charcot's recent remarks on effusions of blood at the fold of the elbow (*Rev. de Chir.*, Sept. 10th, 1881)—i.e., such effusions are not always completely absorbed; the resulting swelling may be as large as an egg, and of cartilaginous or osseous hardness, though at first independent of the bone they may subsequently become attached to it; they remain stationary for a long time, and are but little affected by treatment; and finally they may give rise to errors of diagnosis, being mistaken for exostoses, or detached and displaced fragments of bone.

I am indebted to my friend, Mr. Court, of Staveley, for the notes of the following case.

CASE 1.—Mr. R. A., aged thirty-six, a farmer. On the 24th of March, 1881, whilst out hunting, his horse galloped through a bog, fell and rolled upon him, the saddle pressing against his loins. When first seen by Mr. Court there was a large brawny swelling the size of a cheese plate over Scarpa's triangle; the testes were swollen, the scrotum nearly black, and a hard ridge was felt in place of the spermatic cord. No fracture of the pelvis could be detected; he could move both legs freely; and got up from his bed and passed water without admixture of blood. The swelling in the right thigh became very inflamed, and had every appearance of suppurating, but at last it gradually subsided, leaving a hard gristly substance the size of a man's thumb, which was apparently attached deeply to the tissues below the inner end of Poupart's ligament. During the summer of 1881 the substance became harder and more prominent, and projected beneath the skin of the thigh like a piece of stray cartilage, but gave rise to no pain and very little inconvenience. Absorbents were applied to it for some months without any effect, and its condition remained exactly the same

until March the 10th of this year, when Mr. A— was again thrown from his horse, falling violently upon a hard road. He received a severe scalp wound, and was much shaken. Upon examining the swelling in the thigh, it was found to have become quite flattened, and driven in, as it were, upon the deep structures of the thigh, and for a fortnight Mr. Court thought it would remain so; but gradually it resumed its former shape and size, and in June, 1882, it was as large and prominent as it was twelve months ago. He can ride without any pain or trouble, the only inconvenience being a feeling of weakness in getting his leg into the stirrup.

On Sept. 20th, 1881, when Mr. Court brought this patient to me, there was a mass as hard as bone, and of the size and shape of a man's thumb when the last phalanx is fully flexed, situated at the inner and upper part of the right thigh—i.e., where the thigh joins the pubes and perineum, and over the origin of the long adductor muscle. It could not be made to move, and when seized between the finger and thumb gave me the impression of being connected by its own convex border with the body and ramus of the pubis. I was informed that it had been diagnosed by another surgeon as a portion of the pelvis fractured and displaced from its position beneath Poupert's ligament, downwards and inwards towards the perineum. But the condition of the patient when first seen after the accident, no less than the outlines of the pelvis months afterwards, was completely at variance with this opinion.

CASE 2.—A gentleman, aged forty-three, was sent to me by my friend Dr. Murray of Weymouth-street, on November 22nd, 1881, on account of an injury received whilst riding ten days previously. The horse reared, and the rider suddenly gripping him felt something give way, and then immediately experienced a sensation as of something warm trickling into the flesh near the right groin. Much swelling and discolouration of the skin of the thigh and groin quickly followed, but had in great part disappeared before I was consulted. There still remained, however, some swelling near the junction of the thigh and perineum over the upper end of the long adductor tendon. Tenderness was caused by pressure, and severe pain was felt when the adductors were put into action. I ordered a spica webbing to be worn, which was made by Mr. Hawksley, at my direction, so as to resemble the body portion and one thigh, cut short, of a pair of drawers, padded softly over the origin of the adductors. I also advised the patient to abstain from horse exercise for a few weeks. No other treatment was requisite.

## THE RIDER'S SPRAIN.

By EDWARD HENDERSON, M.D., F.R.C.S. EDIN.

WHEN riding across a small water jump in the country, in the neighbourhood of Shanghai, the muscles on the inner side of my right thigh seemed suddenly to give way, and this sensation was attended by pain of so acute a character that I was for some minutes with difficulty able to retain my seat in the saddle. On dismounting I found myself at once in a position of comparative ease, and soon discovered that, while a good deal of continuous dull aching was felt along the inside of the thigh, really acute pain only attended movements of adduction, such as are necessary to retain the seat securely on horseback. There was considerable tenderness along the course of the long adductor, and acute pain was experienced when pressure was made on the tendinous origin of that muscle, which had clearly been rather severely sprained. I am now (at the end of a week) almost free from pain in walking, but am still quite unable to ride.

This accident, which I have termed "rider's sprain," is, it would seem, of constant occurrence, and well known to horsemen. I have myself seen or heard of many cases of varying degrees of severity. The pain experienced at the moment of its occurrence is generally of a very acute character. One gentleman who sustained this injury when galloping, fainted after dismounting; the inside of his thigh became subsequently much discoloured, and he was for many weeks unable to mount a horse. Another showed such signs, of collapse that

his companion, a surgeon, supposing he was ruptured, wisely made the necessary examination on the spot. The point of greatest tenderness is apparently in all cases in the upper and inner part of the thigh, directly over the tendon of origin of the adductor longus muscle; but it is not, of course, to be supposed that the sprain is necessarily confined to a single division of the muscular mass concerned in the movement of adduction. A man who has once sustained this injury at all severely is liable to its recurrence, and in a few cases permanent weakness is left behind. In one example which came under my notice the sprain, a tolerably severe one, recurred twice in the same thigh, with an interval of some years. In another, the particulars of which were narrated to me, permanent weakness resulted, the sufferer being compelled to give up horse exercise entirely. We suppose here that the accident may occur more frequently in riding China ponies than with full-sized horses, on account of the difference of grip. A horseman who mounts a China pony for the first time usually experiences a sense of insecurity arising from the comparatively narrow clasp of his legs, and the small size of his mount in front of the saddle. When the rider and his horse have warmed to their work in crossing country, the accident seems less likely to occur, being more commonly met with when a fence or water jump is taken in cold blood, or at the beginning of a run; hence it is that this sprain is so frequently complained of as arising from an apparently trifling cause. Some awkwardness in sitting or some unexpected movement of the horse is at the bottom of most cases. Time and rest will of course cure the greater number of these cases, but, in addition, a broad elastic bandage firmly applied over the upper part of the thigh and secured by a figure-of-8 turn round the waist is, as I have myself found, of very material assistance at first in locomotion. A sporting friend tells me that stirrup leathers are sometimes used to support the injured muscles; they are turned twice round the upper part of the thigh and buckled on the outside; men who have once suffered from such a sprain, carrying their spare leather in the country in this way as a protection against a recurrence of the accident. The stirrup-leather can, of course, be easily slackened or tightened to suit the convenience of the wearer. A broad piece of girth-strap with double buckles would give a better support, and would have the advantage of some degree of elasticity. Doubtless the surgeon's instrument makers at home have been often called on to supply suitable supports in these cases.

I should myself like much to know whether the accident is really as common as I am at present inclined to suppose it, and whether the peculiar seat of the cavalry soldier increases or diminishes his liability to this form of sprain. Sprains of the quadriceps extensor muscle are specially referred to in some surgical text-books, but I have not yet come across any special notice of the same injury affecting the triceps adductor.

Shanghai.

## MOTOR DIATHESIS OF THE SECONDARY PERCEPTIONS.

By BRIGADE-SURGEON T. OUGHTON, A.M.D.

SECONDARY perceptions are the subjective indices of the primary qualities existing in external entities—viz., position (distance and direction), dimensions (superficial and solid), magnitude, and motion. Irrefragable evidence has been offered by the eminent Locke, proving these qualities to be primary as affixed in natural objects; but he has failed in a recognition of the fact that, in the sensorial transformation from actualities to phenomena, the not infrequent crosswise action is now in exercise, whereby their mental equivalents can only be regarded as being secondary—that which is primary in the object becomes secondary in the perception. Neither will it be amiss to consider that here is precisely the block of error on which several systems of philosophy have stumbled, noteworthy among them being the ideational hypothesis of Berkeley and the intuitional conceptions of Kant. Medical philosophy scouts the Berkeleyan notion that the world is purely mental dynamics, neither does it accept the modification of Kant that the products of special

sensation are *à posteriori*, whilst those of extension and form are *à priori*—i.e., intuitions in a pre-existent mind. Rather is the foundational basis of our philosophy comprised in Locke's dogma, that the brain is a "tabula rasa" at birth, and mind (spirit excluded as appertaining to the province of faith) is a sequence of the interactions of physical and vital forces. Thus we proceed with our duties relying on the realism of externalities; objective experiences may float past the senses and leave even memory out of sight, but none the less have they been realistic episodes in the phenomenal history of time.

Primary perceptions *pari passu* are the subjective indices of the secondary qualities of external entities, such as colour, temperature, &c. These statements may be verified by annexments as follows:—Special perceptions of secondary qualities are primary in point of development, for the organism of special sensation is fully equipped at birth; but a recognition of the geometrical features of objective nature is a slow acquisition, requiring the motor experience of months or years for its perfect expression. Taking a solitary instance of each class of perceptions, every obstetrician must have sympathised at some time with the keen disrelish of the new-born infant for its cool atmospheric bath; and many of us know that a chicken will seize a grain of barley immediately on exit from its shell. In the latter case, however, we cannot argue from the chicken to the infant excepting on the datum that this will grasp a crumb of bread and feed itself. (Of such kind is the absurd generalisation of those affecting horror at the cruelties practised on a decapitated frog, because it purposively removes a drop of vinegar that is stinging its nether extremities.) Locke is evidently at one with us in the gradual acquirement of the perceptions of primary qualities by his admission that sight restored from congenital blindness would be unable to distinguish between a triangle and a square; still, as we observed before, he has failed to identify these perceptions as being of a secondary nature.

Special perceptions are also primary in point of importance, seeing that they may operate independently of the presence of secondary perceptions; the latter, for instance, are absent in the olfactory and auditory senses. None would hesitate to admit that the qualities of direction, distance, size, or form are wanting in odours; but it is otherwise with sounds. Some would grant that size, form, and motion were wanting in the appreciation of sounds, whilst they might be sceptical about the direction and distance of sounds; yet a careful attention must lead to the conviction that sonorous directions and distances are delusional perceptions, that they are judgments based on the comparison of differences in sonorous intensity, and that such judgments are oftentimes erroneous. Regarding the case of direction, if one should attempt to guess the direction along which an approaching carriage is proceeding, whether from right or left, he will find his guesses by no means invariably correct. I have heard the whistle of a distant train at a railway station, and inferred that it was coming along one pair of lines, but the train has presently made its appearance on the opposite pair. So, with sonorous distance, the ear cannot be said to perceive it in the light of a stationary ventriloquist throwing his voice to all conceivable distances, and, we might add, in every possible direction. But, to continue the argument, secondary perceptions are not independent of the primary—that is, directions and distances, sizes and shapes, &c., cannot be perceived in the absence of an objective. When the biceps is contracted into a hard cord the active cohesion of the sarcois elements communicates no sense of weight in the absence of a felt resistance. So, similarly, on rolling the eyeballs in darkness no visible notion of direction or motion is experienced, excepting as attached to the dim spectra of retinal irritation; and, in the sense of touch unaided by sight, the position of the limbs is determined by a certain indefinite increment of temperature (the true primary sense of feeling) being present, or if not by a memorial comparison. A clearer test on this point is furnished by the faculty of articulation; no evidence of direction, &c., is elicited by the voluntary contractions of the tongue, because the air in contact therewith is impalpable and of an even temperature. Hence, that which is essential is primary, and that which is an adjunct is secondary.

The preamble has been a lengthened one, but not more so than the complication of the subject has demanded; it has been necessary to define and justify the titular phraseology "secondary perceptions," by indicating that primary

objective qualities are the equivalents of secondary subjective qualities, and to note the error that has crept into mental philosophy by Locke's almost culpable disregard of the fact. Neither should it be overlooked, as regards the latter point, that perceptions are only to be construed as being primary and secondary in their mutual relationship as physiological functions, and that both varieties of perception are secondary in their relation to objective qualities. Herein, then, consists the basis of a sound realistic philosophy, and I desire to show—(1) that the organism (muscular) of the secondary perceptions is correlated to the mechanical forces of nature in like manner as that of the primary perceptions is correlated to the sense-essences of nature; (2) that sensorial streams of the primary qualities are transmitted centripetally through the channel of motor nerves in like manner as those of the secondary qualities are transmitted centripetally through sensory nerves. This being done the *modus operandi* of the process must remain for future research, both experimental and logical; query—(1) in what degree is the formative force of natural cohesion correlated to the vitalised cohesion of voluntary muscular contraction; and (2), admitting the correlation, is such vitalised cohesion idealised into the secondary perceptions, by means whereof sensorial form is conformed to natural form?

It must be impressively maintained, firstly, that perceptions are divisible into the two distinct classes of primary and secondary; there is the same *raison d'être* for the classification as for that of the qualities of bodies. The secondary perceptions have been very strangely slurred over by physiologists. Where do we read that the deltoid and superior rectus originate upward ideas, or the biceps cubiti and internal recti ideas of proximity? How does it happen that the said perceptions are apt to be treated metaphysically instead of physiologically, except it be on the unwholesome lead of Locke which insinuates indirectly that they are of a primary nature and therefore, perforce, mentally intuitive. But, concerning classification, note the following words of this philosopher: "There is no discoverable connexion between any secondary quality and those primary qualities that it depends on." He continues—and observe how he mixes up qualities and perceptions—"We are so far from knowing what figure, size, or motion produces, for instance, a yellow colour, or sweet taste, or a sharp sound, that we can by no means conceive how any size, figure, or motion can possibly produce in us the idea of any colour, taste, or sound whatsoever; and there is no conceivable connexion between the one and the other." One inference only is justifiable from this premise—namely, with two sets of perceptions must be adequately conjoined a duplicate nervous instrumentation; the retina can no more perceive direction or visual form than light can *per se* be shaped or assimilated to specific direction, and *eodem modo* the muscular contraction of volition can in no wise be productive of a sensation any more than a given shape, size, or motion, can *per se* originate light, temperature, or the elasticity of sound. We recognise the fact that special nerves are the channels of primary perceptions; where else, then, shall be discovered the second distinctive and instrumental innervation of perception saving in the motor nerves?

A very good rough method of inculcating that the secondary perceptions constitute a class by themselves and are generically akin, that one form of nervous instrumentation suffices for their excitation, and that such instrumentation is motor in its nature, is comprised in the consideration that "each and every" phase of this class of perceptions is expressible by means of straight lines. (a) Drawing a straight line points directly to a motor causation for the perceptions of motion, of direction (that of the line), and of distance (the length of the line). (b) Describing any configuration, as a hexagon, reveals the instrumentation of the perception of shape, and the varying extension that may be bounded by any such configuration furnishes a clue to the agency of apparent size. (c) An angle indicates the profile of a relief, and the relief becomes real on rotation of the containing superficies about a vertical line. Euclid's point is not a metaphysical conception, but the residuum of an antecedent muscular precept; the point has position, being significant of an appreciated direction and distance. Neither is there aught of intuition in any problem or theorem of geometry; these are naught but the refined adjustments of precedent muscular experiences.

Thirdly, the gradual acquisition and development of these perceptions impress the conviction of their motor origin, which is sufficiently patent in the analogous

acquirements of articulation and ambulatory progression. All observation confirms their gradual acquisition, from Cheselden's youth restored to sight to Charles Bell's note that an infant cannot realise the pain of an abdominal blister. The powers of primary perception are intuitive; but a muscular education is necessary for the identification of the roundness of the solar disc, the magnified resplendence of vision, the length of the arm, or the difference between a picture and a solid reality. Coupling in this behalf the facts that shapes are acquired perceptions, and also the chief originating elements of the signs of intellectualism, we may conclude that the radical principle underlying a soundly educated mind resides in the due admixture of sports and study. In a hygiene of intellect the art of drawing (mainly perspective) should be recommended, and instruction of the schoolboy in modelling and sculpture, if practicable, would develop the more realistic perception of relief; but pre-eminently let alternate exercise for mind and body be strictly enjoined, and on an unwavering principle that man's intelligence is in the main founded on his muscular organism in its conjunction with a suitable mechanical configuration.

It is essential, again, that the distal terminations of the nerves of special sense should be mobilised by muscular contraction for the production of secondary perceptions. The vestibular sac is immobile between the cochlea and the semi-circular canals, and no muscle plays directly on the Schneiderian membrane; hence, the absence of this class of perceptions in the auditory and olfactory senses. It may be suggested here that the auricles of some animals are volitionally mobile; truly, but no pure sonorous perception of direction is generated thereby, and the result is an inferential perception such as we gain concerning the direction of an odour by turning the head towards its source. The mobility of the tongue is associated rather with articulate speech than with objective impulses; nevertheless, very keen directive and distal perceptions reside in this organ. It is in the senses of sight and feeling that each and every secondary perception is manifest in full exercise; further, the similitude existing between visible and tangible signs is to be referred to the volitional instrumentation that is common to these senses. Bishop Berkeley differs from this position, for he says—"Visible ideas are the signs of the tangible, not by means of any similitude between the one and the other, nor by any natural principle; but having found them constantly conjoined, as the sounds of a language are with the things they signify." His statement is unreliable, for the said ideas are not immutably conjoined, as is language with thought; the tangible sign is a fixed one, whilst the visible sign varies with the position of the visible body, and the discrepancy is adjusted by a mutual tutoring of tactile and ocular motor experiences.

A few anatomical dispositions may be noted, lastly, which illustrate the dependency of these perceptions on a muscular mechanism—1. No voluntary muscle crosses the median line of the body. This disposition may be interpreted as pointing to the necessity for a neutral line of departure being available wherefrom dextral and sinistral perceptions may date their site of origin. 2. Corresponding articulations are paired on the same level; otherwise double touch would be a constant concomitant of the sense of feeling. Thus, unequal segmentation of the arms would cause a tangible object to be perceived at non-corresponding distances or heights. So, analogously, the orbits are deposited on a horizontal level to prevent a quadruplicate displacement of visual spectra; with the eyes mounted on separate level-lines there must co-exist a vertical, in addition to a horizontal displacement, and with what result? It is difficult to conceive of quadruple vision in the absence of four eyes, and the spectra of double vision would probably, in the case alluded to, hold a variedly oblique relation to each other, instead of a constantly horizontal relation, as with normal binocular vision. 3. The ocular recti stretched away from the eyeball forms a perfect Roman cross, clearly in subjection to the exigencies of vertical and horizontal qualities. 4. Muscles passing over two or more articulations effect the selfsame directive perception in the segments concerned in their contraction; the extensor digitorum longus, for example, produces an upward idea whether in extending the toes or flexing the ankles.

Isolated contradictory evidence is of little moment in the enunciation of general truths. Such evidence crops up only too frequently in the study of perceptive experiences, nor would these be the puzzles they are admitted to be without them. It may be urged that certain muscles have multiple

and incongruous uses, which are inconsistent with their being the agents of directive perceptions; thus, the fan-shaped pectoralis major does not present the simplicity, as a directive agent, of the straight ribbon-like ocular muscles. But the sound principle of the present argument, additionally corroborative of my stated views concerning erect and single vision, is not to be overthrown by a trifling obstacle of this nature; perception has reference to general results rather than to special muscular adjustments, and one of these results indicates that directive phenomena are affected by muscles influencing one another as well as by the mechanical arrangement of their constituent fibres. Herein I have attempted to show that the perceptions of space are secondary to those of essence, and also secondary to and determined by the elements of objective space operating on a sympathetic motorial machinery. It is confessedly difficult to comprehend the crass blindness of metaphysical philosophy in the light of the foregoing matter of physical and physiological fact.

Forest-hill.

## A NEW HÆMOSTATIC AND SURGICAL DRESSING.

By EDWARD THOMPSON, M.B.,  
SURGEON TO THE TYRONE COUNTY INFIRMARY.

SOME months since, at one of the quarterly meetings of the north of Ireland branch of the British Medical Association, I directed attention to the use of the puffball as a hæmostatic and surgical dressing. My attention was first directed to this substance by the Rev. Dr. Discon, the respected rector of the parish of Beragh, who told me that by its means the life of a poor woman, who had suffered for a long period from an open cancer of the right breast, had been preserved for years, and her sufferings much mitigated. I visited this patient, and ascertained that she had tried almost every form of surgical dressing without being in the least relieved either of her sufferings or the constant hæmorrhages which weakened her. In despair she sought the aid of a country quack, who suggested the use of the puffball, or, speaking technically, the *lycoperdon gigantum*, which grows close to the roots of trees in some of our woods, and which, I believe, has gained a solid reputation amongst the country folk. From the day the patient commenced the use of this substance her sufferings were greatly mitigated, and she improved in health and strength. The frequent bleedings ceased, and the foul odour from the sore was greatly diminished; indeed, so admirably did the puffball act, that the poor woman lived in comparative comfort for seventeen years after the first appearance of the cancerous ulceration. But not only does the *lycoperdon gigantum* possess those important styptic properties which would be in themselves more than sufficient to commend its use to surgeons, but it is also a most soft and comfortable surgical dressing, and the powder it contains seems to possess antiseptic and anodyne properties. The puffball is, when mature and fit for use, almost as large as a man's head; it is enclosed in a thin capsule which must be removed, it can then be torn in pieces and used either as a styptic or for applying any required surgical dressing. The puffball undoubtedly possesses the qualities here claimed for it, and this I assert positively (although we live in an age of scepticism), both from my own experience and that of others. It is, however, its hæmostatic properties that seem to me to be so especially valuable; it has the power of stopping instantly even the most violent external hæmorrhages upon which iron, matico, turpentine, &c., have exercised their properties in vain.

Mr. Fagan, the leading surgeon in Belfast, told me a very short time ago that when removing a large tumour from the neighbourhood of the orbit, he encountered the most violent hæmorrhage from large arteries in the bone, which of course he could not tie, and which even pegging with pieces of wool failed to control, yet a small piece of the puffball at once restrained all bleeding. Dr. McKeown has also used this substance, and although he denies that the puffball has any anti-æptic or anodyne properties, he fully concurs in the opinion a number of north of Ireland surgeons have formed as to its complete success as a hæmostatic. I have thus briefly directed attention to this most useful substance, in the hope that some of our leading surgeons will use the puffball, and ascertain for themselves its great utility.

# NOTE ON THE USE OF SALICYLIC SILK AS A DRESSING FOR WOUNDS, WITH CASES.

BY J. LOCKHART GIBSON, M.B., C.M.,

RESIDENT PHYSICIAN, EDINBURGH ROYAL INFIRMARY; PRESIDENT OF  
THE ROYAL MEDICAL SOCIETY, EDINBURGH.

LAST winter I acted as Mr. Chiene's house-surgeon in the Edinburgh Royal Infirmary, and I have received his permission to publish the results we obtained under the use of salicylic silk between the deep and superficial layers of gauze in an antiseptic dressing. What led to the use of salicylic silk was the note of the results obtained in the Leeds Infirmary, published by Mr. Henry Brown in your number of Oct. 8th, 1881. Mr. Chiene did not, however, adopt the Leeds method in its entirety, but, as we think, improved upon it, and so brought out some of the chief advantages of the silk as an addition to an antiseptic gauze dressing.

Our method differed from that used at Leeds in this essential—viz., in the use of no mackintosh. Next the wound was placed a piece of protective of as small a size as possible, and often perforated, as it was used merely to prevent the dressing from sticking to the wound; then two or three

layers of carbolic gauze wrung out of 1 to 40 carbolic lotion; above that a variable quantity of salicylic silk; and over all a large dressing of eight plies of carbolic gauze. The large dressing we used to protect the silk, which was looked upon as an aseptic though not antiseptic reservoir, and therefore required an anti-epic covering to prevent it from going wrong when moistened with discharge. It was not thought necessary to soak the deep dressing in a stronger solution of carbolic acid than the usual 1 to 40. The mackintosh was dispensed with because the use of the beautifully absorbent silk gave us the means of employing what Mr. Chiene had been long aiming at—viz., a dry dressing. The advantages found in the silk were—dryness of our wounds, lessening of discharge, diminution of labour to the surgeon, and cheapness. The absence of the mackintosh allowed the fluid part of the discharge to evaporate, and the dressings, when removed, sometimes not till two or three weeks after their first application, were found to be acting the part of a huge scab and to be covering a healed wound. The discharge was lessened because the poulticing action due to the mackintosh was absent. Our wounds in almost every case were drained with chromic catgut, that dressing might not be necessitated for the removal of a drainage-tube. Horsehair stitches were employed, as being more rigid than catgut; as keeping the lips of a wound in more perfect coaptation, and as being easily removed after a wound is healed.

## CASES TREATED BY SALICYLIC SILK IN THE ANTISEPTIC DRESSING.

No.	Nature of case.	No. of dressings.	Highest temperature.	Remarks.
1	Scleritis of mamma and axillary glands.	1	99° 2'	Dressed on the operating-table. Dressing removed on the fifteenth day. Wound found healed.
2	Scleritis of mamma and axillary glands.	4	100° 8'	Only once dressed for discharge (oozing); twice for drainage-tube in axilla, which had been used because some glands surrounding the axillary vessels, and, therefore, not removed, had been touched with chloride of zinc. Drainage-tube opening healed in thirty days, rest of wound in thirteen days.
3	Trephining for compound depressed (punctured) fracture of skull.	1	99° after 1st day, when it was 101° 6'	Bone, to the size of a crown-piece, removed from vertex. Dressing removed on the fifteenth day. Wound found healed. Dismissed a month after admission.
4	Railway injury reflecting the scalp from nearly the whole of one side of the head, and baring and scratching the bone for an area of two inches in diameter.	1	99°	Dressed on the eleventh day, and found healed.
5	Amputation through the middle of thigh, for cario-necrosis.	4	99°	Healed on the seventeenth day. Dressed on the first, fourth, tenth, and seventeenth days.
6	Five wounds of vertex, three penetrating to the bone, and one exposing a fissured fracture.	1	99°	Dressed on the twelfth day, and found healed.
7	Primary amputation below the shoulder.	5	99° 5'	Drainage-tube used because flaps were doubtful. Only two of the dressings were necessitated by discharge.
8	Syme's amputation at the ankle (primary).	10 (3 for discharge)	100°	The frequent dressings were necessary for the watching of a linear slough of the heel-flap, which had been injured by the accident. The case was in for eight weeks. Very good stump.
9	Compound fracture of tibia and fracture of fibula.	2	99°	Dressing removed in twenty-one days. Wound found to be quite superficial, with distinct union of bones. In another fortnight the wound healed, and patient was dismissed.
10	Compound fracture of tibia.	3	100°	The patient (a woman) had fracture of the true pelvis and of a rib, in addition to the tibial injury. Dismissed in six weeks.
11	Compound fracture of tibia and fibula, and compound dislocation of the ankle.	12	101°	The case was a very serious one, but left the hospital in nine weeks with the wound healed and a movable ankle. The last five dressings were not necessitated by discharge.
12	Primary amputation of middle and index fingers, with portions of their metacarpal bones.	3	99°	Healed on the twelfth day.

## ON A CASE OF MALIGNANT CHOLERA.

BY J. EDWIN COONEY, L.F.P.S.G., &c.

MRS. C—, of Poplar, E., aged fifty-two, of spare habit, after three days of premonitory diarrhoea, during which period she dosed herself from a neighbouring druggist's to no effect, sent for me on June 21st, 1882. Arriving at 8 A.M. I found her shrieking and groaning, tortured by spasms of the carpo-pedal extremities, &c., which were purple; the countenance had assumed the "facies cholericæ," the eye being deeply sunken, red and injected, a broad and livid band encircling the lower part of the orbit; every feature was sharp and pinched, the complexion thick and muddy, and the lips and tongue purple. The whole body was bathed in a cold and clammy sweat; the voice scarcely audible. Temperature (external) was below 95° F.; pulse not appre-

ciable in wrists and superficial arteries. One of the heart's sounds only detected. Vomiting and purging incessant. She was passing painless motions of the true choleraic character—viz., copious white flocculi suspended in a watery fluid; urine was entirely suppressed since 4 A.M. She was, moreover, extremely restless and tossing about. In other words, she was in the algid state of malignant cholera. At 8 A.M. ice was given *ad lib.* to suck, also twenty grains of chloral hydrate, with twenty minims of dilute sulphuric acid in a little ice-water, which was rejected. This repeated at 8.30 A.M. was again vomited. At 9 A.M. I gave her a dose of chloral alone (twenty grains), which was retained; and up to 6 P.M. I gave ten grains of chloral every half-hour. Vomiting occurred occasionally in the intervals, but the drug was never rejected. At 10 A.M. I found the bladder empty on passing a catheter, and resolved to inject a pint of tepid water in it to procure its absorption. The symptoms were still urgent, though the sweating and restlessness had ceased, and the cramps were shorter in duration and further between. At noon, on passing the

catheter to carry out my resolution, I found a fluid ounce of urine in the bladder after eight hours' suppression. By 3 P.M. the thermometer marked 96° F., and at 6 P.M., after taking 180 grains of chloral in nine hours, I noted the external temperature at 96.2° F.; the pulse was coming back, and the muscular spasms had disappeared, and she had vomited five times; her motions were of the same character as before, but less frequent, and shortly before 6 P.M. she expelled a little urine with an alvine evacuation. From 6 P.M. to 6 A.M. the following morning she had five grains of chloral every half-hour, with the exception of two hours' interval during the middle of the night, when the symptoms were observed to become more urgent and the temperature fell below 95° F. She had a teaspoonful of beef-tea, iced, every half-hour. Chloral, 100 grains.

June 22nd, 1882, 6 A.M.: Temperature 98.4°; eight stools during night, when urine was passed; during the day five grains of chloral every half hour=120 grains of chloral. 6 P.M.: Temperature 97°; pulse 120; vomited twice; ten stools; both heart sounds heard; face and extremities still cyanosed; five grains of chloral every hour through the night=sixty grains of chloral.—23rd: Temperature 97°; pulse 110; respiration laboured, and 35 a minute; thick purulent sputum brought up frequently (patient states "she usually suffers from chronic bronchitis, and that there is consumption in the family"); coughs for the first time since illness; she is very drowsy, and complains of pains in the head; bowels opened eight times through the night, and stained with bile; five grains of chloral hourly, with dilute sulphuric acid=sixty grains of chloral. 6 P.M.: Temperature 97.8°; pulse 100; respiration 24; sputum less; two grains and a half of chloral hourly, with acid=thirty grains of chloral.—24th, 6 A.M.: Temperature 97.8°; pulse 96; cyanosed appearance almost gone; bowels moved six times through the night, and of a better consistence. The patient is still very drowsy, and has to be roused for nourishment; milk and beef-tea ordered. 6 P.M.: Four stools; temperature 98°; still drowsy; ordered cold to head, and one drachm of brandy every two hours, with nourishment as before; no chloral given this day.—25th, 6 A.M.: Temperature 97.8°; purged three times; not so drowsy; no stimulants or medicine. 26th: Temperature normal; no relapse or reactionary fever.

*Remarks.*—This case has many points of interest to one who has seen much of cholera, but through want of space I will simply allude to a few. There are only six cases on record in this country with a premonitory diarrhoea of three days' duration, and this is another. Besides, it is the only case in which suppression of urine lasted only eight hours, the other shortest period being ten hours. Hydrate of chloral was given to an alarming extent—i.e., 180 grains in the first nine hours, and a total of 550 grains or one ounce and a quarter in three days. Though the freshest drug by Liebreich was used, all the usual effects of large doses were not observed, and it is questionable whether the subsequent drowsiness was due to chloral or a natural sequence of the disease. Further corroborative evidence is necessary to prove whether chloral, besides checking sweating (as in phthisis) and preventing vomiting (as in sea-sickness), has any action on the kidney secretion, similar to nitrite of amyl. Probably such toleration of larger doses of chloral is due to the loss of the inorganic blood salts by transudation of blood serum *via* intestinal canal. The early cessation of the vomiting precluded the employment of chloral hypodermically. The administration of the drug was thorough, and the case assiduously watched throughout conjointly by Mr. G. Edwards, a Calcutta colleague, and myself. Other medical men also saw the case. It would be interesting to know what quantity of chloral given hypodermically is equal to a given quantity given by mouth. The early appearance of the urinary secretion prevented my putting into practice my plan of injecting the urinary bladder with water, which originated with me, and is not generally known, and which I communicated to THE LANCET with cases some time ago. As the patient and her friends objected to my making internal thermometric observations (per vagina or rectum) I am unable to produce them.

London.

## NERVE-STRETCHING FOR SUPRA-ORBITAL NEURALGIA,

WITH REMARKS ON NERVE-STRETCHINGS AND THEIR BEARING ON THE MODE OF TRANSMISSION OF NERVE IMPULSES.

BY AUGUSTUS H. BAMPTON, M.D., M.Ch.,  
ASSISTANT-PHYSICIAN TO THE PLYMOUTH PUBLIC DISPENSARY, ETC.]

ELISHA S—, aged sixty-nine, a farm labourer, was admitted to the South Devon and East Cornwall Hospital at Plymouth on March 7th, 1890, suffering from what has been termed epileptiform neuralgia affecting the frontal branches of the first division of the fifth. He had had these attacks of pain off and on for about eighteen months, and the severity had increased so that for the last three weeks he had taken to his bed.

His family history was good, being the father of ten children, nine of whom were still living. There was no nervous or rheumatic history, and nothing remarkable about his general condition, except that he complained of pain across his chest and shortness of breath, accounted for by dyspepsia and the age of the tissues. The pain was confined to the right side, and was most intense over the orbit. The right pupil was widely dilated with profuse lachrymation. The skin was hyperæsthetic, so that a touch would bring on a spasm of pain, and a shade had to be worn over the eye to prevent the impression of light inducing a spasm; the pain was excruciating, rendering life a burden. He was ordered a pill of quinine and iron and a belladonna liniment, subsequently altered to aconite liniment and phosphorus pill, and the application of the continued current over the painful spot. Under this treatment he improved somewhat, the phosphorus being increased to one-fifth of a grain daily, and he relapsed when the battery had to be sent away for repair. At this time he had about forty paroxysms of pain a day. To relieve this nitrite of amyl inhalation was given with some benefit, temporary only; so that on June 23rd, at Dr. Clay's request, under whose care he was, Mr. W. Square cut down on the supra-orbital branch of the frontal nerve, and stretched it with a blunt hook, just behind its entrance to the supra-orbital notch, without much difficulty, with the immediate result of cessation of pain. The wound healed by first intention, leaving no perceptible scar, and up to July 19th, the date of his discharge, he had only a slight pricking pain at the outer angle of the eye. In the way of drugs he had lately been taking the saccharated carbonate of iron and cod-liver oil; so that here we had almost complete relief from pain following a most simple operation, after a patient trial of many remedies, in so painful a disorder that Trousseau declared he had not seen in his experience ever radically cured by any means.

For neuralgias of an epileptiform character nerve-section was the last resource up to 1869, when Nussbaum accidentally discovered the efficacy of nerve-stretching, a procedure which has been carried out some fifty or sixty times in the last few years, in the majority of cases with permanent benefit. In tetanus nerve-stretching has been employed, but I am not aware with any constant measure of success. Although in locomotor ataxy the relief by nerve-stretching as regards pain and improvement in other symptoms has been well ascertained, and was admitted on all sides at the discussion on the subject at the International Medical Congress, and Professor Morgan, of Manchester, mentioned a case of idiopathic lateral sclerosis, where stretching of the left sciatic gave considerable relief as regards pain in both limbs, and temporary disappearance of ankle clonus on the side operated on. The difficulty is to find a satisfactory explanation for the effects of the operation. How is it brought about in such cases? It is generally considered a sufficient answer in regard to neuralgias of inflammatory origin, where adhesions have taken place, that it is the breaking down of such adhesions that effects the cure; but what is the mode of action where other conditions obtain? Professor Eulenberg believed that it consisted in a deficiency of centripetal conduction being brought about. If so, it would be useful only in those nerve lesions of a local character where lesions in nerve centres were of a secondary character. The mode of transmission of nerve impulses is involved in the solution of the ques-

THE Royal Commission on Metropolitan Sewage Discharge met on Tuesday, at 20, Great George-street. Present—Lord Bramwell, in the chair; Sir John Coode, Prof. A. W. Williamson, Dr. De Chaumont, Dr. Thomas Stevenson, Mr. James Abernethy, and Dr. W. Pole (secretary).

tion: it is not yet recognised whether it is vibratory or chemical. By the vibratory hypothesis is understood a displacement or vibration of the nerve molecules, just as atmospheric atoms undergo displacement or oscillations in the transmission of sound; and it has been suggested that sensorial impressions, transmitted to the nervous centres, may be taken and reproduced by those organs in the same manner that the diaphragm of the telephone receives and reproduces the respective motions impressed upon it. By the chemical hypothesis is understood an absolute chemical change in the particles of the nerve-substance when in a state of activity, by virtue of which change nervous impulses are propagated, just as chemical mutations occur in other animal organs during their physical activity. Professor Charles alluded to a third hypothesis, in a paper read at the Cork meeting, which Dr. Meryon called the electrical hypothesis, whom I quote, by which is understood the development of electrical action in every nerve particle by virtue of a dipolar attribute, by which every nervous molecule adds its quota to the evolution of a force closely allied to, if not identical with, electricity; although having regard to the correlation of forces, the possible transmutation of either one of these forces into another must be borne in mind. The efficacy of nerve-stretching seems to me to point rather to the truth of the vibratory hypothesis, and if we believe that pain is the result of an inordinate and disorderly set of vibrations, and that nerve-stretching, like the percussion of Dr. Mortimer Granville, sets up a new set of vibrations, which interrupt or change the morbid set by introducing discord,—this would explain the action of the electric current in arresting pain by altering the number of vibrations; for a galvanometer shows a decrease of deflection if the current be made to pass through a nerve in an opposite direction to that of the natural nerve force, this latter being just so much neutralised by the inverse galvanic current, as if their molecular motion were interchangeable. But, if this be true, we still have this difficulty of which to give an account—viz., Why should the change be permanent for good? Callender thought that the stretching is of use by numbing the nerve for a short time through breaking the transit of the abnormal impressions conveyed along the fibres of the nerve, so that in the interval thus gained the centres may have resumed their natural control. But if that were so, nerve-section would have the same effect; but it is not so. Walsham quotes Vogt in his belief that we must look for the cause of the relief obtained by nerve-stretching in some alteration in the irritability and nutrition of the nerve trunk or of its peripheral terminations, brought about by the stretching of the bloodvessels of the sheath; and that it is not due to any primary effect on the nerve centre or in the conducting power of the nerve, because the traction is not conveyed to the central organ. But though direct mechanical traction may not be transmitted to the central organ, Professor Eulenberg believes, on the other hand, it to be essentially due to centripetal impulses of a dynamic agency, of a nature as yet unknown, of a peripheral traumatic influence on the corresponding smaller or larger territories of circulation and nutrition in the central organ; and we know it must have an effect on the central organ, because it often not only has a favourable influence on the leg operated on in *tubæ dorsalis*, but also on the other. Dr. Müller gives an instance in a case where when the left crural nerve was stretched the sole reflex disappeared; yet at the same time there appeared in the other leg, which was not stretched, hyperæsthesia and hyperalgesia, a clear sign that in man the effects are the same as Brown-Séquard noted them to be in animals; and Dr. Austie believed all neuralgias to have a central origin, not traumatic. Thus it would appear that nerve-stretching is likely to be of service in neuralgias whether of central or peripheral origin. Uspensky believed neuralgia to be dependent on the retention of acid products of metamorphosis of the nerve tissues, with subsequent weakened function of the vaso-motor nerves, atrophy of sensory nerve cells, and change in the calibre of the vessels, with loss of their tone. It seems that, as there are neuralgias dependent upon diverse causes, some associated with recognised structural changes, others only of a functional character, the action of nerve-stretching may work differently in such cases, in some cases by removing or breaking down a fibrous adhesion, as in neuralgias and epilepsies of traumatic origin, and in some cases of tetanus brought about by peripheral irritation; in some cases by simply interrupting a vicious habit of irregular molecular nerve impulses. That such effect is possible is

shown by the phenomenon of negative variation taking the place of the ordinary nerve current on the application of an electrical or mechanical stimulus; in others, due to imperfection of the local blood-supply, or a vice of development on the part of the tissue elements, by altering the blood-supply through the calibre of the vessels, thus inducing nutritive changes in the nerve cells and increasing their molecular stability. Nerve-stretching may act in all these ways in one case. This is, I believe, only the second time that the supra-orbital nerve has been stretched, and was no exception to the rule that after stretching a single branch pain occurs during convalescence in a different branch of the same nerve, and is another instance that when neuralgia attacks the ophthalmic division of the fifth it usually affects the supra-orbital branch.

I learn that the patient continued free from pain for nearly three months from the time of the operation, and it returned at intervals during the following winter. I take it, in this case, the mischief was centric. It may turn out that it is only those cases where the nerve storms are set up by peripheral irritation that derive permanent benefit and complete cure is effected by stretching; and that where the origin is centric, the bad habit is only interrupted for a time in most cases. But considering the simplicity of the operation, it should always be resorted to when other treatment fails in this most painful affection.

## A NEW INDICATING AXIS-TRACTION FORCEPS.

By A. DRUMMOND MACDONALD, M.B., C.M. EDIN.

THE leading points in the design of this instrument are—

(1) axis-traction without the use of intra-vaginal rods; (2) indication of the grasp taken of the fetal head; (3) portability; and (4) minor deviations from the ordinary type of long forceps, partly suited to the three preceding points, partly by way of improvements. How this design is practically carried out is shown in the accompanying woodcut and following description.

Taking the parts *seriatim*: (a) The blades are 6½ in. long, 2½ in. apart at the widest, and 1 in. apart at their extremities, which are not quite so broad as usual. When applied, and traction made, they will "give" half an inch, a point to be observed in all forceps, according to the temper of the steel, and having an important bearing on the question of grasp. The total breadth is 1½ in., the fenestrum being ½ in., leaving ⅞ in. steel, which ensures a good hold. The fenestrated portion has been made nearly straight, and the pelvic curve lies in the lower portion of the blade and upper part of the shank, for the reason that when the blades are in apposition to the head, at or entering the pelvic brim, the natural curve of the genital canal lies below the head, consequently below the blades, and so corresponds to the curve above indicated. What we want is a pair of forceps acting as straight forceps, but without their perineal inconvenience, capable of being applied with facility, and at the same time adapted to the curve of the pelvic passages. (b) The shank measures 2½ in. (with the blade 9½ in.). This should prevent any locking in the vagina. (c) The lock is a kind of hybrid between the British and Continental locks, and allows of a scissors-action of the blades for the purpose of indication mentioned below. The lower blade has, and is easily recognised by, a hooked portion of the lock, on which the upper rounded and shielded segment is slipped in locking. (d) The handles have upper movable halves attached to the lower by a hinge joint which admits of their being folded down from right angles, so as to be easier of manipulation when required, and occupy smaller space when not in use. There are holes for a transverse traction bar through their ends, between which is a space for

the middle finger to be passed through when grasping this bar. (e) The indicator is seen as a scale on the flat convex side of the binding-screw (c), passing through the centre of the hinge, and shows how far the extremities of the blades, when in position, are apart, within a range of one to three inches. This will indicate whether a sufficient grasp has been obtained to avoid risk of slipping; and if the exact presentation and movement be taken into account, will give an idea of the measurement of the diameter of the head we are dealing with. For portability's sake the traction-bar may be screwed into the head of the binding screw. (f) Mode of application: The handle is not to be brought so far back towards the perineum as must be done with long forceps generally. Then having inserted the screw and read off its index number, raised the movable part of the handles, and placed in position the transverse bar, traction is to be commenced (assuming that the head is at the brim) with the bar opposite the tip of the coccyx, so that the line of traction (A B) shall pass through the axis of the brim. The hand is of course to be moved forwards as the head descends. The forceps are dark bronzed, to take away the formidable aspect that bright polished or plated instruments wear in the eyes of outsiders. Messrs. S. Maw, Son, and Thompson have given me a ready assistance in carrying out my endeavour to produce an "instrument of precision."

### IDIOPATHIC OR PERNICIOUS ANÆMIA, ASSOCIATED WITH JAUNDICE.

By W. T. PARKER DOUGLAS, B.A., M.B. CANTAB.

THE following is a typical case, so far as its clinical history is concerned; and its connexion with jaundice may probably be accounted for by an excess in the fatty degeneration of the liver (which frequently forms an element in the pathology of cases of pernicious anæmia), due to the habits of the patient.

G. R. H.—, aged seventy. Had been a strong, active, muscular man, of full habit and florid complexion, fond of sport and of good living. He inherited gout, and perhaps helped to incur the same, which first made its appearance at the age of thirty; of late years he had constantly arrested its development by patent medicines containing colchicum. Two years ago he was laid up with phlebitis of the left femoral vein, and since then his strength and health had been failing, though at Christmas last he was able to walk two or three miles. He persevered with his duties as a clergyman till June 5th (the last occasion of his officiating in the church). With increasing weakness slight jaundice supervened, and persisted to the last. Of late there had been not infrequent blood loss from hæmorrhoids and by epistaxis. Such is a short history of the case prior to his coming under my observation on September 3rd, in consultation with Dr. Phillips, of Hurstbourne, when his appearance was as follows: Well built, fairly nourished, no lack of fat, slightly jaundiced, and of a deepish lemon-colour over head, face, and neck, but much paler over rest of body; skin dry and waxy, with a few small ecchymoses on extremities, and light-brown pigmentations, the seats of former petechiæ; lips and mucous membranes pale; slight anasarca over whole body; eyes with wildish, anxious expression; arcus senilis highly developed; tongue furred and dry; breath rather offensive; pulse 96, soft, and very compressible; heart-sounds faint, with systolic (hæmal) bruit at base; some of the veins in both upper and lower extremities easily traceable for some distance, and hard as whipcord. No enlargement of liver, spleen, or any of the glands; breath-sounds faint, but normal; urine tinged with bile, but free from albumen; bowels generally costive, and motions of an ochry colour. Sickness supervened on taking nourishment; and besides the liquids swallowed, the vomit was mixed with darkish, grumous mucus. Temperature just below normal.

Between Sept. 3rd and 6th there was constant sickness, slight epistaxis, and lastly hæmatemesis, to the extent of a pint and a half, followed by extreme exhaustion and death.

A specimen of the blood was taken from the finger on September 4th, secured in a capillary tube, and examined by microscope six hours afterwards, when I noticed as follows:—No tendency on the part of the red corpuscles to collect into rouleaux; about two-thirds were normal in out-

line and size, the rest most irregular in shape, some being of equal dimensions, with healthy red corpuscles but granular, others larger, indefinite in outline, elongated, or forming masses having the appearance of red corpuscular detritus, many of which were twice or three times the size of normal white corpuscles: these latter elements were not increased in numbers beyond the natural proportion, but varied in size, some being barely a third of the dimensions of the larger normal white corpuscles, thus corresponding nearly with observations made by Messrs. Mackern and Davy on the blood in a case of idiopathic anæmia published in THE LANCET for May, 1877.

Newbury.

### AN INTERESTING CASE OF BRANDY POISONING.

By J. A. OWLES, M.D. ST. AND.

ON Tuesday, May 16th, I was summoned to see a gentleman in a "fit," and found him lying on the floor of his bedroom in a deep sleep, with evidence of having recently vomited, and with a slight bruise on the right temple and another on the right thumb, which confirmed the supposition of a fall. His breathing was laboured, but not exactly stertorous; his heart's action was very weak and his pulse variable; the pupils were unequal, the left being a good deal contracted. It was difficult to rouse him, and impossible to get any information from him. A lady and gentleman (relatives) and the proprietor of the house in which he was lodging were present, but could throw little light on the history of the case. They said that he had come to Bournemouth for change after a very severe attack of inflammation of the right lung, that he was a little over thirty years of age, that he had been walking about "too much," and that he had been complaining of neuralgia. A friend had given him, a few hours previously, a glass of port wine, and he had also taken a "little" brandy. He had been sleeping a good deal upon the bed during the morning, but was not heard to fall, and no one knew what had happened until he was found upon the floor. Three bottles were upon the mantelpiece: one containing a tonic mixture with steel in it; a second, some creosote for local application; and a third was an ordinary brandy bottle half full. There was no reason to suspect poisoning, either wilful or accidental. The only odour perceptible in the breath was that of brandy, and it seemed unlikely that this was the cause of his illness, as he was an habitual abstainer from alcoholic drinks. We undressed him and used mild measures to keep him from sleep until we could ascertain more accurately his condition. As soon as his clothes were removed, Mr. T. B. Scott, surgeon of this town, who had also been sent for, entered the room. We then gave a little ammonia with belladonna, and some coffee, and put mustard to the legs and strong smelling-salts to the nostrils. The vomit, which had previously been scanty and somewhat like froth and treacle, was now much increased; inequality of the pupils was more marked, and the difficulty of keeping him awake was greater; but with the remedies named we roused him sufficiently to get his own account of what had happened. He admitted, in reply to close questions, that he had taken during the day, in six to eight hours, about half a bottle of brandy for the neuralgia, and added that, though an abstainer, he always took it when suffering pain. It was evident, therefore, that this was the primary cause of his fit, and that the brain pressure resulted from it. Being convinced of this, we allowed him to sleep, watched by a nurse, and left him for two hours; at the expiration of which I returned and found him somewhat better, though still drowsy.

May 17th: The patient had passed a fair night and felt much relieved, but there was still inequality of the pupils and partial loss of sight in the left eye. He also complained of a "creeping" sensation at the "top" of the head near the centre, and occasionally extending to the forehead and eyes. I gave some bromide of potassium and gentian, with a little aconite for the neuralgia, and a dose of calomel with rhubarb for the bowels.—18th: The pupils nearly equal, the sight of left eye normal, and the "creeping" sensation less. He then gradually improved, till one week after the "fit" he was well enough to return to London.

I have recorded the case for two reasons: 1st, be-

cause of the combination of symptoms of alcoholic poisoning and apoplexy obscuring diagnosis; 2ndly, because of the somewhat remarkable effect of half a bottle of brandy upon an habitual abstainer.

Bournemouth.

## CRURAL NEURALGIA AFFECTING DENTISTS.

By J. B. SUTTON, L.R.C.P. LOND., M.R.C.S., &c.,  
DEMONSTRATOR OF ANATOMY, MIDDLESEX HOSPITAL.

ON June 20th I was called to a gentleman said to be suffering severely from sciatica. The patient was resting on his right side complaining of intense pain in the left loin, radiating thence along the outer and anterior aspect of the left thigh whenever he attempted to move. Firm pressure, applied between tuberosity of ischium and great trochanter of femur, was painless, but the instant one touched the skin immediately over the erector spinæ muscle severe pain was evoked, extending down the thigh to the knee-joint, mapping out exactly the course of the anterior crural and external cutaneous nerves. Pressure over the points of exit of the second, third, and fourth lumbar nerves from the spinal canal caused excessive pain. The nerves at fault were clearly the second, third, and fourth lumbar, the hyperæsthetic area in the loin clearly corresponding to the distribution of the posterior divisions of these nerve trunks. The case was obviously not one of sciatica, but crural neuralgia, having a very unusual distribution; the ordinary forms of this disease extend to the foot and toes of the affected leg. Belladonna and aconite were applied locally, strychnia internally; the patient was convalescent in seven days.

Two days later a similar case came under my notice, and a third has been reported to me with exactly similar symptoms. Curiously enough, the three patients were dentists engaged in the active duties of their profession. It appears exceedingly probable that this painful affection may be explained by the fact that when dentists operate they always stand to the right side of the patient, consequently, when manipulating cavities in teeth difficult of access, it is necessary to throw themselves into a constrained attitude, whereby the lumbar vertebrae are slightly flexed anteriorly, but flexed laterally to a considerable degree. It is necessary sometimes to maintain this cramped position for long periods, the temporary distortion being even more exaggerated when the dental engine is being used. These combined flexions cause the lumbar nerves to become congested, irritated, and possibly injuriously nipped as they pass through the intervertebral foramina, thus giving rise to the symptoms detailed above.

## A Mirror

OF

## HOSPITAL PRACTICE, BRITISH AND FOREIGN.

## CHARING-CROSS HOSPITAL.

A CASE OF RHEUMATOID ARTHRITIS TREATED BY LOCAL APPLICATIONS OF IODINE, AND BY SALICYLATE OF QUININE INTERNALLY; REMARKS.

(Under the care of Dr. POLLOCK.)

FOR the following notes we are indebted to Mr. Wigan, resident medical officer.

Eliza M—, aged twenty-five, was admitted on June 1st, 1882, complaining of rheumatic pains in the wrists, knees, and feet. She stated that she was perfectly well till the age of twenty-three. Up to that time she had been very stout, only complaining of occasional headache. In August, 1879, she caught cold and was laid up for three weeks with acute rheumatism. She resumed her duties as domestic servant, but still complained of occasional rheumatic pains. In the spring of 1881, the pains became much worse, but she

did not take to her bed, being still able to do a little work. At the end of six weeks, being still unfit for work, she went down to St. Leonards Convalescent Home, and remained there for six weeks.

She returned to her situation in August, 1881, and kept fairly well up till Christmas, when she was obliged to give up altogether. She was just able to walk with difficulty, and her hands were almost useless. She noticed that the joints (especially the carpo-metacarpal) of the wrist and also the tarso-metatarsal joint of the big toe were increasing in size. These swellings steadily increased, and at the time of admission there were very apparent thickening and crepitation on rubbing the surfaces of the carilages together. No other joints were yet affected. Her father and mother had both suffered from chronic rheumatism; one brother had rheumatism two or three times, but he died of phthisis at the age of twenty-three.

On admission on June 1st the temperature was 99°; pulse 90. She was placed on a low diet, and given the following:—Two grains of sulphate of quinine, two grains of carbonate of ammonia, and twenty grains of bicarbonate of potash, in water, three times a day.

June 5th: As she did not improve, and still complained of constant pain in the wrists and feet, she was put on a generous diet—viz., meat and vegetables, two eggs, three ounces of wine, and an extra pint of milk. The mixture was stopped, and instead she took five-grain doses of salicylate of quinine, in the form of a pill, three times a day. This after three or four days relieved her much. She lost all pain in the joints, and was able to bend them freely. On the 6th the joints of her hands and feet were ordered to be painted every second day with a liniment of iodine, which was continued up till July 6th, except on one or two occasions, when it was stopped on account of the irritation of the iodine. On the 7th the patient left for St. Leonards Convalescent Home, having lost all pain in the hands and feet, and being able to move all joints without difficulty, five weeks having elapsed since her admission, during which time the temperature had never been higher than 99.8°.

*Remarks.*—Dr. Pollock observed, with regard to this case, that, bearing in mind the frequently intractable nature of the disease, the result obtained by the treatment was very satisfactory. The importance of good feeding has been long ago pointed out by Dr. Garrod, and the liberal diet had probably much to do with the improvement of the patient. But from experience of similar cases, Dr. Pollock is inclined to attribute benefit to the continued use of the iodine paint over the affected joints, and also to the administration of the salicylate of quinine, a drug which he believes to be well worthy of an extended trial in all cases of rheumatoid arthritis where the joints are not hopelessly disorganised.

## RADCLIFFE INFIRMARY, OXFORD.

CONGENITAL HYDRONEPHROSIS SUCCESSFULLY TREATED  
BY ASEPTIC INCISION IN THE LOIN AND  
DRAINAGE; REMARKS.

(Under the care of Dr. TUCKWELL and Mr. H. P. SYMONDS.)

A BOY, aged eleven, was admitted under Dr. Tuckwell's care on June 22nd, 1881. His family history was good, and he had been always remarkably healthy, having never received any injury nor complained of any pain. His mother stated that she had not noticed anything unnatural in the size and shape of his abdomen till about fifteen months before admission, when it had struck her that the left half looked larger than the right. Since then there had been a steady increase in the size of the left half, but the boy's health had not suffered in the least; there had been no pain, no increased frequency of micturition, nor any change in the natural appearance of his urine. The boy had a remarkably healthy and cheerful look. On examining the abdomen, a large swelling could be seen bulging forward the whole of the left and part of the right side. A clear wave of fluctuation was felt over the whole of the tumour in front. When he was turned on his face, the left lumbar region behind was also bulging, and fluctuation was clearly communicable from the front to the back. There was neither pain nor tenderness in any part of the swelling, which was uniformly elastic, giving to the hand the sensation of fluid in a tense, thin-walled sac. Dulness on percussion reached from the sixth left intercostal space, in the nipple line, to within two inches of Poupart's ligament.

A line drawn from below the left nipple to a point three inches to the right of the umbilicus, and thence obliquely across to the left iliac fossa, marked the boundary of the tumour to the right. A line drawn from the same point above obliquely downwards and backwards to the vertebral column marked the limit of the tumour to the left and posteriorly. The only resonant part of the abdomen was the right flank. All the rest was dull; nor could any line of resonance in front of the tumour, such as would be caused by the descending colon and assist in the diagnosis of kidney disease, be recognised. The urine was quite normal. This large sac containing fluid was thought to be either a cyst connected with the left kidney or a hydronephrosis, probably the latter; and as there was an entire absence of pain or other history to account for it, it was thought to be probably congenital, due to some malformation of the ureter, not large enough to attract attention till within the last year or two, when it had increased more rapidly. Although it gave the boy no pain and did not interfere with his breathing, yet, from its size and prominence, it was clear that a slight blow or push might rupture it and cause death by peritonitis. It was decided, therefore, to do something for the boy's relief.

On June 27th, Mr. Symonds introduced an aspirator needle into the most prominent part of the tumour in front, and drew off from three to four pints of turbid, dark-brown fluid, without smell, having a specific gravity of 1008, and containing altered blood, albumen, and urea. No bad symptom followed the operation. The sac gradually refilled, and the boy left the infirmary on July 14th in much the same state as before the operation.

He was readmitted on December 7th. He had been quite well, and had suffered from nothing but the inconvenience caused by his great size, the tumour being even larger than it was when he left the infirmary. The question of repeated tapping with the aspirator, on the one hand, and of laying open the sac behind and draining, on the other, was discussed, and the latter course was chosen because of the rapidity with which the sac had refilled after the first operation.

On January 2nd, 1882, the boy was put under ether; an aspirator needle was passed by Mr. Symonds into the sac in the loin behind, so as to avoid the peritoneum; an incision, an inch and a half in length, was carefully made by the side of the needle well into the sac, and a large drainage-tube was passed in with little difficulty, the cyst walls yielding before the finger. The usual Listerian precautions were rigorously carried out. Fluid of the same character as before flowed freely through the opening, and as soon as this had ceased running, antiseptic dressing was applied. For the following eight days the wound was dressed daily under the spray, till on January 9th scarcely any discharge came away in the dressings, at the end of twenty-four hours, and no remains of the tumour could be felt in the abdomen or loin. The temperature, which was 99° on the evening before the operation, rose gradually to 103° on the third evening after, and then fell to 99° on the eighth day.—10th: The large drainage-tube was to-day removed and a smaller one put in. The same evening the temperature rose to 103·8°, and the following two evenings to 103° and 102°. The sac refilled with marvellous rapidity, till on the 12th of January it had reached a larger size than before the operation, and was even more tense. There was a narrow line of resonance in the right flank, but the rest of the abdomen was absolutely dull and fluctuating.—13th: The boy was again put under ether. On passing the finger into the opening in the loin it was found that the small tube had not penetrated into the sac, the opening into which had slipped under the edge of the muscle, and the contents had been thus prevented from escaping. The finger was then pushed on into the sac, when a gush of dirty-looking inodorous fluid, mixed at last with blood and pus, in quantity about four pints, took place. A long, full-sized tube was re-introduced well into the interior of the sac, and antiseptic dressing was applied as before. From this time onwards there was only steady progress towards recovery to record. The temperature fell on the fourth evening to 98°, and for the rest of the time that the boy was under treatment never rose above 101°, ranging from 98° to 100°, till it fell to and remained at normal. The wound was dressed at first daily, then every other day, inodorous pus, in gradually diminishing quantity, draining off into the dressings.

March 8th: The large tube was taken out, and one of the same length, but of smaller size, put in.—29th: The tube was shortened to an inch and a half in length.

April 6th: The tube was removed, thirteen weeks from the date of the operation.—10th: The patient got up, an antiseptic dressing being fastened on the wound by plaster.

May 10th: The wound had quite healed; the abdomen appeared symmetrical; no tumour could be felt; the percussion-note in the left flank was not quite so clear as in the right, but not dull, nor did it alter on changing the boy's posture. There was a slight puckering in of the skin at and around the wound.

June 16th: A careful examination of the abdomen showed no sign of any return of the tumour. The boy was quite well, and at school.

*Remarks by Dr. TUCKWELL.*—So little is to be found in books on the subject of the treatment of hydronephrosis that the above case may be worthy of notice. Thus, in Ebstein's chapter on the therapeutics of this disease, in Ziemssen's *Cyclopaedia*, nothing can be more unsatisfactory than the results there given of operative interference in such cases. After reading it, one is inclined to leave the disease to itself rather than meddle with it in any way. He says, "The puncture of hydronephrotic sacs is dangerous, because an outbreak of general peritonitis is always to be feared. It is generally of little value, because the sac is likely to refill in a short time." He also records a case of treatment by incision which proved fatal. But, judging from the boy's case herewith reported, it would appear that in a young subject, provided that a normal urine indicates a healthy state of the other kidney, the operation of antiseptic incision in the loin and drainage may be safely undertaken. Tapping with the aspirator is followed by so rapid a refilling as to make one fear that repetitions of this might go on for an indefinite time. Supposing an incision to have been made, a point to which attention may be especially drawn is the danger of removing the drainage-tube too soon. These sacs seem to retain immense power of refilling, till at least many weeks of drainage and gradual shrinking have passed by. A gradual puckering in of the skin at the seat of incision seemed to mark the gradual contraction of the sac, and might, perhaps, be looked for as a favourable sign in any future case of the kind.

#### GOCULDAS TEJPAL HOSPITAL, BOMBAY.

LARGE ELEPHANTOID TUMOUR OF SCROTUM, WEIGHING FIFTY-SIX POUNDS; REMOVAL; RECOVERY.

(Under the care of Surgeon-Major T. CODY.)

A MUSSULMAN, aged thirty-five years, was admitted for a large elephantoid growth involving the penis and scrotum, and also for a similar growth occupying the left leg. The man was a scrofulous subject, and had some open suppurating sores in his neck, where also some old cicatrices were visible. He was anxious to be operated on; but as he was in a delicate state of health on admission the operation was put off for about a month. He had tonic treatment, under which his general health much improved. The tumour reached below the knees, and the penis had retracted into the growth. The prepuce was healthy, as was also a small patch of integument corresponding to the dorsum of the penis. For three hours before the operation the tumour was raised above the level of the body, and at the same time an indiarubber bandage (Esmarch's) was bound round it. When the patient was brought under chloroform the glans penis was searched for, and drawn out and grasped in the left hand, together with the piece of healthy integument before referred to as corresponding to its dorsum. An incision was then commenced at the lower margin of the prepuce, and carried upwards and backwards on the right side as far as the root of the penis; it was then carried downwards and outwards for about five inches, going through healthy integuments and dividing it and the subjacent tissues in its course. The fingers were now used to tear through the fasciae and search for the cord, which was easily found. Its course was followed down till the testicle was reached and freed, nothing but the fingers being used to do so; and both being found healthy they were turned up on the abdomen and held there in position by an assistant. A similar incision was then made on the left side, and the fingers used as before described to divide the deeper layers of fascia. The search for the cord was embarrassed by a large hydrocele, into which a long incision was made and the fluid allowed to escape, which must have amounted to at least twenty-five pints. After this the cord was

easily found, but the testicle was observed to be diseased, so it was removed and the cord secured. The incisions were now carried round the root of the tumour, going very close up to secure healthy integument, and three or four touches of a Catlin divided the mass. The arteries, which had been clamped as they were divided in the course of the operation, were now secured, and it was found that only four required ligature, the pressure of the small clamps having proved sufficient to effectually close the smaller ones. The right testicle, which was preserved, was now brought down and placed in the centre of the wound, the surface of which was washed with carbolic water. Three sutures of silver wire, each of which was passed through the covering of the testicle, were inserted in the lower portion of the wound, and stretched and twisted so as to give an inward tendency to its margins, without, however, bringing them into apposition. Two other sutures, above the situation of the testicle and at the root of the penis, were inserted, and a little stretching brought the margins of the wound at this point into apposition. The healthy piece of integument and the prepuce were attached also by wire sutures to the subjacent tissues and the margins of the wound, though they could not be brought into apposition. The whole surface was now covered with carbolised oil dressing, over which a thick layer of carded oakum was placed, and the whole kept in position by a *langvotu*. This article of the East Indian's dress requires explanation. It is a piece of cloth attached behind by a knot to a string passed round the body above the hips, and brought forward between the legs, spread out to envelope the penis and testicles, and fastened again to the string above the pubis. There was no oozing after the operation, and the dressing was not removed till the second day. After four or five days it was found that the integument had adhered to the tissues round the testicle, as it had also in other parts; and the wire sutures were therefore removed and the wound allowed to granulate.

There was some suppuration and free discharge for about a fortnight; but as soon as the ligature of the left spermatic cord came away the discharge lessened, and the wound steadily though slowly continued to heal and contract, and his general health to improve till he left the hospital about two months after the operation. Some three months after leaving the hospital he showed himself. He then looked hale and well; the disease in his leg had considerably lessened, and gave him little or no concern; and the cicatrix, which was quite smooth and healthy looking, occasioned no uneasiness. He quite retained his virile powers. The solid mass removed weighed fifty-six pounds, and it was calculated that during the operation some thirty pounds of fluid must have escaped.

## Reviews and Notices of Books.

*Antiseptic Surgery: its Principles, Practice, History, and Results.* By W. WATSON CHEYNE, M.B., F.R.C.S., Assistant-Surgeon to King's College Hospital, Demonstrator of Surgical Pathology at King's College. With Illustrations. London: Smith, Elder, and Co. 1882.

IN the volume before us Mr. Cheyne has made a very valuable addition to surgical literature. The intimate professional relations of Mr. Cheyne with Professor Lister give a special importance and value to this work; for while Mr. Lister's results and views have hitherto been published only fragmentarily in journals and the Transactions of learned Societies, Mr. Cheyne's book affords a trustworthy and complete statement of them. The work is dedicated to Mr. Lister, and this fact may be taken as proof that he accepts as accurate the statements contained in it regarding himself. We do not say this from any intention of minimising the writer's part, but only to point out that the book is *more* than any mere individual production of that gentleman could be. The title of the work expresses concisely and accurately its plan and contents. The scientific groundwork on which Mr. Lister's treatment was originally founded and firmly rests, receives very full and careful treatment from Mr. Cheyne, who deals first with the theory of fermentation, tracing the history of the particulate theory up through all its stages, from Lavoisier to

Tyndall, and demonstrating the undoubted establishment of this theory. In a similar historical and complete manner, the struggle over spontaneous generation, heterogenesis and abiogenesis, is passed in review, and the reader is led almost irresistibly to adopt the conclusions on which antiseptic treatment of all kinds rests. The author is at pains to distinguish between Mr. Lister's special treatment and what we may group together as the various modifications of it which are practised by many other surgeons. It is maintained that the former may and should be called the *aseptic treatment*, because it attains "a complete absence of putrefaction—an asepsis"; while the other methods of treatment "by which the occurrence of putrefaction is more or less interfered with," and which "all act on a more or less imperfect principle," should be called *antiseptic*. This is by no means a verbal quibble, but is a distinction so important as to demand clear recognition and verbal expression. Mr. Watson Cheyne has himself during recent years taken no inconsiderable share in the experimental investigations which form the basis of the aseptic treatment, and we anticipate much more valuable work from him in the same department. In view of this we may perhaps offer him some advice as to his style. He cannot help being a partisan, and no one with any knowledge of the history of the discussions that have ever gathered around the "germ theory" can now look for any investigator to be altogether free from bias. The author, however, has guarded himself by free quotations from the writings of those whose views do not coincide with his own. But in several places he has allowed himself to speak with but scant courtesy of the opinions therein or elsewhere expressed by these gentlemen. Any such expressions altogether fail in their purpose, and rather prejudice an impartial reader against the cause pleaded by him who uses them. We think we could refer to several passages which would have been far more effective for Mr. Cheyne's purpose if this point had been more carefully observed.

The part of the book which will perhaps be erroneously called the more practical part, deals with the materials used and the exact mode in which they are employed in Mr. Lister's aseptic treatment, and then specifies the results obtained by it. Of the former we need say nothing, except to point out that nowhere else can a surgeon find this information so fully given. The results of the aseptic treatment are detailed with great fulness, nearly half the volume being devoted to their consideration. Mr. Lister's statistics are given with minuteness and great care, as well as tables of all his cases of compound fracture, wounds and incisions into joints, and abscesses connected with disease of the vertebræ, treated in hospital since 1871, the details of each case being stated. In addition we have the statistics published by Volckmann, Nussbaum, Socin, Esmarch, Hueter, Reyher, Spencer Wells, Keith, and Thornton, and many others of Mr. Lister's disciples; and as far as possible statistics of surgeons using other forms of treatment are presented for comparison, but there is a great want of really trustworthy facts on which to found such a comparison. The reader, however, hardly needs them. We could easily summarise these statistics, but we prefer not to do so. Such summaries are proverbially untrustworthy, and certainly not generally credited. We prefer to urge our readers to study this book for themselves, to master the *scientific facts* on which an aseptic treatment is based, and to study diligently the *clinical facts* which Mr. Lister and his close imitators show. Only those who have taken special care to keep themselves *au courant* with the rapid strides of this department of biology are aware of the immense mass of facts on which the "germ theory," as it is popularly known, rests. Those who do not may innocently speak of it as an "unproven theory," but a careful study of Mr. Cheyne's *résumé* will, we fancy, dispel this illusion. The clinical facts are so striking that surgeons but a generation ago would have rejected a prophetic description

of them as an empty dream of the impossible. Hitherto the information on which to base a sound opinion on both the theory and the practice here urged has been so difficult to obtain, except by those specially engaged in this field of scientific research, that surgeons have had some excuse for ill-formed opinions and judgments. But such excuse can no longer exist. Within 600 octavo pages can now be found all that is needed to make the question clear to any mind, and ignorance on this point on the part of any one claiming to be an educated surgeon will be inexcusable; and it needs no prophetic vision to foretell the effect of the spread of a more complete knowledge of the subject.

Mr. Cheyne has published his book at a most opportune time; he has abundant facts to make his position good, and he has been able to state his case so completely, that we believe the issue of this work will be a starting-point for the more general adoption of Mr. Lister's treatment in this country. Never before could the course of aseptic surgery be pleaded so effectively—nowhere else has it been stated so fully—and we cannot believe that British surgeons, who hitherto have been foremost to avail themselves of all life-saving improvements of their art, will be backward in accepting this, the greatest of the century.

*Manual of Diseases of the Skin.* With an Analysis of 8000 Consecutive Cases and a Formulary. By L. DUNCAN BULKLEY, A.M., M.D., Attending Physician for Skin and Venereal Diseases at the New York Hospital. Crown 8vo. London: J. and A. Churchill. 1882.

DR. BULKLEY of New York, who is well known as the translator of Isidor Neumann's Handbook of Skin Diseases, the author of a recent treatise on "Eczema and its Management," and as the editor of the "Archives of Dermatology," has now set his hand to supply a manual or introduction to the study of diseases of the skin. The book had its foundation, apparently, in the clinical conversations and pharmacopœia of the New York Hospital, and in preparing the work for the public Dr. Bulkley has endeavoured to make it concise, and yet sufficiently detailed to be of practical value to the student and practitioner. The author prefaces the consideration of the various diseases by a brief sketch of the anatomy and physiology of the skin, an outline of etiology, and a few general observations on diagnosis, or how to set about, and what to pay attention to in, observing skin disease (including an explanation of the elemental lesions). There is a chapter on the relative frequency of diseases of the skin, founded on 8000 cases observed by the author. The nomenclature and classification are based on Hebra's arrangement. Diet and hygiene are specially discussed, and there is a final chapter on therapeutics, and a very complete index. The excellent formulary is an important feature, and will be valuable to practitioners, especially as the treatment of each disease is pretty fully indicated. In the body of the manual pathology is but very briefly considered, and the differential diagnosis is hardly entered into at all, which is, we think, to be regretted. Excellent as the book is in many respects, we fancy we can trace signs of hurried or careless writing. To particularise a few instances, beyond the general composition of the book, we fail to find any description of what in England is known as miliaria, and in the mere mention of Lichen tropicus nothing is said of its occurrence in the tropics, but only that it is seen commonly in infants. Urticaria papulosa (Lichen urticatus) is pre-eminently a children's affection, but Dr. Bulkley merely observes that it is "most commonly seen in children." Tilbury Fox's dysidrosis, too, does not occur "especially upon the backs of the hands and between the fingers," and from among the causes of Pruritus vulvæ, diabetes is omitted. Then, although such a local affection as framboesia is described, no mention is made of the Oriental sores nor of guinea-worm disease.

*Experimental Physiology; its Benefits to Mankind.* By RICHARD OWEN, C.B., M.D., F.R.S. London: Longmans, Green, and Co. 1882.

THIS little treatise is a powerful attack on the absurd efforts of the anti-vivisectionists to repress the scientific investigation of disease by means of well-devised physiological experiment; and it is very cheering to find a man occupying the distinguished position of Professor Owen speak with such decision on points respecting which his knowledge is a thousandfold superior to those who have been so misguided as to legislate on subjects of which they know so little. The high position which Professor Owen has long held amongst the savans of Europe, his wide knowledge and great ability, and his thorough familiarity with the points at issue, entitle him to speak with great authority on experimental physiology, and he speaks with no uncertain sound. He shows clearly that those who argue in favour of total abolition of vivisection on the ground of humanity do practically prevent the discovery and application of means for the relief of suffering humanity. It is true, the consistent "bestiarian," as Professor Owen terms the anti-vivisectionist, may say, "I never had an ovarian tumour or a Fallopian pregnancy. Let those women with such complaints get rid of them as they can. My mission, with the help of a lord chief justice of England, a cardinal, an archbishop, bishops, peers, baronets, heads of colleges, is to haul up to Bow-street every experimental advancer of physiological science as an immoral offender, an unfeeling inhuman wretch, a displeaser of Almighty God, a horrible torturer of his creatures." Professor Owen not only defends the experimental physiologist by irony and ridicule of his opponents, but more seriously points out the many important advances and valuable acquisitions to our knowledge that have resulted from experiment. Professor Owen has incorporated the address he delivered at Folkestone on the occasion of the unveiling of the statue of Harvey in the present volume, which will be read with satisfaction by all those who have the true interests of science at heart.

*The Surgery of the Rectum.* Comprising the Lettsomian Lectures on Surgery delivered before the Medical Society of London, 1865. By HENRY SMITH, F.R.C.S., Surgeon to King's College Hospital, &c. Fifth Edition. London: J. and A. Churchill. 1882.

IT is almost superfluous to do more than notify the fact that Mr. Smith has been called upon to furnish another edition of his well-known book. He has added to this edition a short introductory chapter on the examination of the rectum, which, like the rest of the book, is brief and to the point. Mr. Smith's increased experience has served only to intensify his confidence in his clamp and cautery for the cure of hæmorrhoids and prolapsus ani. He has found it answer equally well in the most trivial and the most severe and extensive operations, and he feels justified in recommending its general use without any fear. Like all other modes of treatment, it requires to be used with care and attention to certain details, but when these are observed he has failed to notice the unfortunate results feared by others. He mentions some of the more recently introduced methods of operating, only to state that he has seen no sufficient reason to abandon a thoroughly successful and well-tried plan, for any one of them. By an oversight, no doubt, Mr. Smith advises complete division of the sphincter ani for nearly all cases of fistula in ano. A very large proportion of such fistulae result not from abscesses in the ischio-rectal fossa, but from anal abscesses, and in these the thickened skin and mucous membrane only are divided, and the sphincter is left entire. Only in cases of fistula running into the ischio-rectal fossa is it necessary to divide the sphincter, nor, indeed, is it ever done in others.

*The Student's Guide to Diseases of the Eye.* By EDWARD NETTLESHIP. Second Edition. pp. 395. J. and A. Churchill, New Burlington-street. 1882.

MR. NETTLESHIP has made considerable additions and, we think, improvements in the present edition. He has introduced a chapter on "optical outlines" which gives to the student all he needs to know with respect to the action of lenses and prisms on light. It is, however, a subject for regret that such a chapter should have to be placed at the head of a work on diseases of the eye. If school education were properly conducted, if a preliminary examination of an appropriate character for those entering the profession were insisted on, the information here given would be regarded as rudimentary, and might be replaced with one showing the application of higher mathematics to the optical properties of the ocular media. A set of seventeen coloured papers with descriptive letterpress has been added to illustrate the subject of colour-blindness. Holmgren's wools are mentioned, but Mr. Nettleship does not refer to Dr. Thomson's very convenient set of coloured wools which enables the observer to refer to previous notes with facility. Mr. Nettleship has the authority of Skeats, which is great, for spelling lacrymal "lacimal," but it is unusual. The work will be found very useful both by the student and the practitioner, and the rules laid down for treatment are sound and valuable.

*Modern Dress and Clothing in its Relation to Health and Disease.* By T. F. PEARSE, M.D. London: Wyman and Sons. 1882.

WITHOUT committing ourselves to the details of Dr. Pearse's little book bearing the above title, we cannot but welcome the appearance of any and every rational attempt to enlighten and impress the public, and particularly the female section of the community, with the need of promptly correcting obvious errors of policy in respect to clothing, and the wisdom of breaking loose from the fetters of fashion and adopting a more reasonable and healthy style of costume. We can see at a glance that the brochure to which we have alluded embodies views which we do not entertain, and would not, therefore, endorse, but it is on the whole a valuable and opportune summary of the more important facts about dress, concisely stated, and as such will be certainly useful. The first step on the way to radical reform must be independent thought, and it is not to be expected, nor indeed desired, that all should see alike on this important subject. We are agreed as to more prominent evils of the modern type of dress, and see together as to the measures to be taken with a view to amend these errors. Dr. Pearse quotes largely from Mr. Treves, and he could not cite a more able and popular recent writer.

*Burdett's Official Intelligence.* London: E. Couchman and Co.

APART from its interest and value to all who invest or deal in any of the innumerable financial securities known to the London Stock Exchange, "Burdett's Official Intelligence" for 1882 is remarkable both as a reflex of the enormous proportions and infinite varieties of our means for investing national savings, and as a statistical *tour de force*. Viewed in either of these three aspects, this first issue of the work under notice, with its more than 900 pages of well-arranged information, undoubtedly meets a decided want, and fully merits its favourable reception in the financial world. The work, which has been prepared under the direction of, and is officially issued by, the Stock Exchange Committee, purports to contain a carefully compiled statistical *précis* of information respecting all British, colonial, and foreign loans and companies, comprehending as far as possible "all joint-stock enterprise at home and abroad." It is proposed to re-issue the volume annually under the editorship of the secretary of the Share

and Loan Department of the Stock Exchange, Mr. Henry C. Burdett, long and favourably known to the readers of our columns for his contributions bearing upon the respective merits of large and small hospitals, and upon hospital statistics in general. The value of this work is immensely enhanced by its official character, which impresses with confidence the assertion in the preface that each edition is intended to present "a colourless and neutral, but thoroughly trustworthy *précis* of information concerning all classes of securities." The securities of which detailed information is given are not solely those "officially quoted," but include all others which the editor, after careful investigation, deemed to possess any public interest. A statistical account is given of every security which is quoted in any list issued by any Stock Exchange in the United Kingdom. The present volume contains a summary and notice of all the new companies—about 1400 in number—which were promoted during last year, and the introduction contains a short historical summary of the growth of the Stock Exchange, coincidently with the increase in the number and value of financial securities. In 1697 the first "Official List" was issued by the Stock Exchange, under the title of "The Course of the Exchange," and contained particulars of but six securities, chiefly Government Stocks, and up to 1811 their number had only increased to twenty. From the alphabetical index to "Burdett's Official Intelligence," beginning with "Abbot, John and Co.," and ending with "Zoedone Company," we roughly estimate that nearly 2400 securities find enumeration and detailed description in the volume. This gives some idea of the growth of invested capital in the United Kingdom since the beginning of this century. The arrangement of the vast mass of information contained in "Official Intelligence" is at the same time simple and satisfactory, and we cannot doubt that as a book of reference the annual issue will become indispensable.

## New Inventions.

"SANITAS," "SANITAS" OIL, "SANITAS" GAUZE.

SANITAS is now widely and favourably known as a disinfectant and deodoriser which possesses the valuable properties of being in itself harmless, and of having a very agreeable odour. The "Sanitas" Gauze is prepared as a dressing for wounds, and resembles in all but odour the more familiar carbolic acid gauze; it is of course free from the toxic effects of the latter, and is certainly possessed of antiseptic powers. The "Sanitas" Fluid is a clear watery liquid which is miscible with water in all proportions, and can be used in the form of spray or lotion. If used pure, it does not cause any local irritation. "Sanitas" Oil can be used for a spray (not so good for this purpose as the fluid), or as a dressing to wounds, either pure or diluted with olive oil, or dissolved in alcohol, or as an ointment. It is possessed of great oxidising properties, the oil being stated to be equal in strength to a ten-volumetric solution of peroxide of hydrogen. This fact, together with its non-poisonous and non-irritating properties, its pleasant odour, and inexpensive price, make this article a very valuable antiseptic agent.

ANTISEPTIC ADHESIVE BANDAGE: HEFTBAND.

HEFTBAND is the name of a new antiseptic adhesive plaster manufactured by A. Hutchinson and Co., at Mannheim, whose London agents are Messrs. Maw, Son, and Thompson. The adhesive material is a preparation of india-rubber; what antiseptic material is employed is not stated. It is a soft supple thin plaster, and is stated to adhere to most surfaces, but the sample examined by us is totally devoid of this antiseptic property.

# THE LANCET.

LONDON: SATURDAY, JULY 29, 1882.

THE process of the coagulation of the blood is of the highest practical importance in surgical pathology, in connexion with the means by which hæmorrhage is arrested. In this special relation the process has been recently studied by HAYEM, whose previous investigations on the physiology and histology of the blood have supplied important additions to our knowledge. These latest researches of HAYEM formed the subject of a recent communication to the Paris Académie des Sciences. They relate especially to the part played by the minute corpuscles to which he has given the name of "hæmatoblasts," a subject which is of interest in connexion with the views of BIZZOZERO on the influence of his *blutplättchen* on the process of coagulation, to which we lately called attention. HAYEM pointed out that ANDRAL, long ago, noted in the superficial layer of blood standing in a vessel, whether pure or mixed with a solution of sulphate of soda, innumerable minute white corpuscles 1-500th of a millimetre in diameter, around which the filaments of fibrin form. VULPIAN, in 1873, observed that some of these filaments seem to proceed from the corpuscles, and RANVIER expressed the opinion that these minute bodies were merely small masses of fibrin, which become centres of coagulation. HAYEM, however, believes that the elements described by these and other authors are merely altered forms of the hæmatoblasts which he described in 1874, and which undergo almost instantaneous change when removed from the body. He has shown that these elements, under abnormal circumstances, possess remarkable viscosity, adhering to one another and to foreign bodies, and that this is the first of a series of changes consequent on which they become the points of origin and of attachment of the filaments of the fibrinous meshwork. Further, he now shows that all the conditions which retard or prevent the coagulation of the blood hinder the alterations in the hæmatoblasts, while influences which facilitate the latter also promote coagulation, a method of proof the same as had been previously adopted by BIZZOZERO. These considerations make it probable that the hæmatoblasts take an active part in the formation of clot which arrests the hæmorrhage from a divided vessel, and of this HAYEM now furnishes conclusive proof. Such hæmorrhage, rapid at first, gradually becomes slower, and finally ceases. The diminution and arrest cannot be explained by the mere contraction of the wall of the vessel, which, although strong in the arteries, is absent in the veins, and could not by itself close the vessel entirely. The actual arrest is by the coagulation of the blood, although it is not easy at first to see why such coagulation should occur at the open mouth of a vessel through which a stream of blood is flowing, and in which, therefore, no stasis takes place. If an incision is made into the jugular vein of a dog, and a ligature be placed on the peripheral portion of the vessel as soon as the hæmorrhage has ceased a small clot can be extracted from the wound.

This clot has the form of a nail, of which the point penetrates into the lumen of the vessel, while the head rests on the outer wall of the vein. If the coagulum is plunged into a liquid which fixes the elements of the blood, it can be thoroughly examined. The point and middle part are greyish, viscous, and composed of a material partly granular and partly amorphous. The granules are constituted by enormous quantities of hæmatoblasts, already altered, but still distinct and separate, while the amorphous material results from the confluence of hæmatoblasts which have undergone still more alteration. The head of the coagulum is red externally, and contains in the centre a prolongation of the viscid hæmatoblastic material, and at the periphery a large number of red globules are contained in fibrillary meshes. In the central portion, which really closes the wound, very few white corpuscles can be perceived. It thus appears that the fibrin is added to an original nucleus, which consists almost exclusively of hæmatoblasts. The formation of this may be watched in the mesentery of the frog. A small vein having been brought into the field of the microscope, it is divided incompletely by means of the point of a small scalpel. The free flow of blood from it soon lessens, the orifice being narrowed by a mass of elements which collect and adhere at the opening of the vessel. In a few moments the opening is covered by a whitish mass, into which the red corpuscles enter with difficulty. Instead of being formed by white corpuscles, as many observers state, this mass is formed exclusively of hæmatoblasts, which are arrested during the flow of blood. At the moment at which the hæmorrhage ceases, these elements are already considerably altered, and undergo further changes beneath the eye of the observer. This hæmatoblastic aggregation contains only a small proportion of white corpuscles. These are spherical, smooth on the surface, and not adhesive, since if the observation is prolonged for a short time, they may be seen to make their way out of the hæmatoblastic mass by their amoeboid activity. They appear to take no part in effecting the arrest of hæmorrhage, and present their normal physiological properties and anatomical characteristics at a period at which the hæmatoblasts are profoundly altered.

In this process the edges of the wound in the vessel appear to act as a foreign body. The hæmatoblasts behave in precisely the same way to an actual foreign body which is introduced into the current of blood. A metallic thread was passed into the external jugular vein of a dog, by means of an extremely fine needle, so that scarcely a drop of blood escaped. At the end of two or three minutes the segment of vein traversed by the wire was emptied by means of two ligatures, one placed on the peripheral and the other on the central portion, and was then excised and opened after having been placed in a liquid capable of fixing the elements of the blood. The wire was already covered by a thin grey layer composed of innumerable hæmatoblasts, individually the more distinct the shorter the time that the wire remained in the vessel. If the wire was for a considerable time in contact with the blood, the collection upon it had precisely the characters of the mass which closes a divided vessel.

Thus the essential part of the process of the arrest of hæmorrhage appears to be played by the hæmatoblasts, which when they arrive at the edge of the wound become

adhesive and collect on it as they would on a foreign body, and to this collection other similar elements are being constantly added from the current of the blood, until the opening is closed and the flow of blood arrested. The other elements in the blood, and the formation of fibrin, only participate in the process in an accessory and secondary manner. The blood contains within itself its hæmostatic; and if all these elements could be conceived to be absent from the blood, the tendency of hæmorrhage to spontaneous arrest would cease.

These facts have an important practical application. Since all foreign bodies alter and retain the hæmatoblasts, and since an abnormal condition of the vascular wall seems to have the same action as a foreign body, we can understand why intra-vascular coagulation occurs upon a portion of the wall of the vessels or the heart which has been altered by disease. So, too, we can understand the hæmostatic action of foreign bodies placed in contact with the surface of a wound, especially powdered or spongy substances, which may serve to collect the hæmatoblasts of the blood. These elements undergo changes the more rapidly under the influence of warmth, and this HAYEM thinks may explain the effect of injections of warm water in arresting hæmorrhage; but in this the influence of the vaso-motor system no doubt modifies the result. In animals it has been found that the more slowly the blood coagulates the less readily do the hæmatoblasts undergo modification. Since these elements may undergo alterations in quantity and quality in various diseases, we can understand that these modifications in the blood may predispose to hæmorrhages on the slightest vascular lesion. HAYEM throws out the suggestion that hæmophilia, the pathology of which has hitherto eluded discovery so completely, may be merely the consequence, or rather the expression of some peculiar condition of the hæmatoblasts. He relates the case of a man, aged fifty years, who was almost dead in consequence of an extreme epistaxis, to which he had been liable for thirty years. An examination of the blood showed a remarkable paucity of hæmatoblasts, which, moreover, underwent changes far less readily than in the normal condition. To this HAYEM attributed the obstinate hæmorrhage, which for three weeks had been renewed whenever the plugs were removed from the nostrils. He therefore proposed to transfuse a quantity of normal human blood, which, containing active hæmatoblasts, might restore to the blood its coagulating power. One hundred and twenty grammes of blood were, therefore, injected, with the effect of immediately arresting the hæmorrhage. After the operation the plugs were removed from the nostrils, but not a drop of blood was subsequently lost. These facts are certainly remarkable, and, taken in conjunction with those described by NORRIS and BIZZOZERO, constitute an important addition to our knowledge of the mechanism of the arrest of hæmorrhage.

WE are inundated with letters on the subject raised by "M.D. Edin." in THE LANCET of July 1st. We regret that it is simply impossible to find room for these communications, which, though very excellent, are also very long. With the greater part of a letter from Dr. BROOM, of Clifton, we must close the discussion on this subject for the present. Both sides have been already fully stated in

our columns. In doing so we shall venture to express a few thoughts of our own on the question at issue.

The letter of "M.D. Edin.," which started the present controversy—which, by the way, periodically arises—is that of a man who evidently has got his education at a university or universities, and who is fortunate enough to possess the degree of the famous and ancient University of Edinburgh. He is grieved that the majority of the profession are at present engaged in the compounding and sale of drugs. He attributes this to the fact that the highest ambition of our English students is to look to the possession of a licence as apothecary; who, however, are not content to be known by the title of "Apothecary SMITH" and "Apothecary BROWN." Still worse: "The principal reason why these men dispense drugs is that they are catering for popularity by the sale of cheap physic. Men who cannot keep their patients while prescribing as gentlemen, instead of tinkering in drugs as tradesmen, have mistaken their vocation," &c. Our correspondent is very anxious to know "from what schools these men came and what qualifications they hold."

We cannot think that our correspondent has done full justice here to the great bulk of English practitioners, or that he rightly estimates the place of medicine and dispensing in medical practice. To take his last point first we will venture at once to say that the men who are selling both drugs and medical advice on unworthy terms are not all mere apothecaries. Very many of them will be found to possess a qualification from corporations north of the Tweed. We are amongst the number of those who believe that the Apothecaries' Societies have fulfilled their functions and should be allowed to retire as licensing medical authorities, but it is only just to them to admit that the cheap doctoring system has been developed since the monopoly of the Apothecaries' Society was abolished by the Medical Act of 1858. Not to dwell on this point, we will next observe that we see nothing essentially degrading or undignified in a medical man supplying good and well prepared drugs to his patients. If the medical calling were like the legal one, in which only comparatively few and wealthy people are concerned, we might concur in demanding with our correspondent that no doctor should soil his hands with drugs. If all the members of the profession could travel the world over and study to find where the profession attains the highest social condition the case would be different. Such is not the happy lot of the bulk of the members of the medical profession. They have to work very hard and for very inadequate sums. Where the poor are not attended gratuitously in dispensaries, as to a large extent is the case in Edinburgh, and in England too, or in Poor-law dispensaries, as in Ireland, they have to be attended on very moderate terms. And it is to the credit of English medicine that a large number of medical men have, up to very recent times, been able to attend the working classes at such terms without loss of dignity to themselves and with advantage to their patients. This is urgent work. The woman in labour and the child with scarlet fever or with scrofula, both parts of a household that has to be kept on 30s. a week, are pressing facts. Such people will never require a barrister. They must have a doctor. Our correspondent may have heard a proverb, "You cannot get breaks of a Highlandman." This is true. It is equally

true that you cannot get from a man with 30s. a week payment for a doctor and a chemist. The least experience of medical practice among the working classes and the humbler trading classes will satisfy anyone of this. So much is this difficulty felt that some of those who are pressed with the problem of securing medical attendance for the poor recommend the creation of a lower grade of medical practitioners than any now existing. We strongly deprecate such a proposal. But the way to bring it about is to speak disparagingly of medical men who are not blessed with degrees, and who dispense their own medicines. We admit that theoretically we should like to see dispensing by medical men abolished. Wherever reasonable chemists can be found, this will be largely practicable in the better ranks of practice. We should also like to see every English workman treat his children daily to animal food, with a chicken once a week. But at present we do not live in Utopia. The medical profession must adapt itself to human society. We have no excuse to offer for false and sham dispensaries, *et hoc genus omne*; but for honest attempts to meet all the medical wants of working and poor people we have nothing but respect, and see no more discredit in supplying them with the drugs they need than in supplying them with the splints or the bandages they may require.

"M.D. Edin." thinks all compounding and dispensing on the part of medical men might be seriously discouraged by a meeting of non-dispensing members of the profession. Another correspondent, whose letter we have not room for, avers that nothing but compulsion will suffice to prevent members of the profession dispensing on the one hand, or chemists prescribing over the counter on the other. Has the latter gentleman considered the probability of getting any possible Parliament in England to consent to the legislation involved in such compulsion?

It is a matter for regret to find that scurvy is again on the increase in the British mercantile marine. The returns of the Seamen's Hospital, Greenwich, show that in 1873 there were 7 cases of scurvy admitted; in 1874, 18; whilst in 1880 and 1881 the numbers rose to 45 and 37 respectively. The cases reported by the Board of Trade for the whole kingdom have risen from 19 in 1874 to 99 for 1881. This, in the face of the statutory enactment as to lime-juice, by which the issue of this antiscorbutic is made obligatory, is most discouraging, and if we were not aware of certain circumstances which may tend to explain this increase of the disease, our faith in the prophylactic virtue of lime-juice might be somewhat shaken. There are certain points, however, which we think account for the recent increase of scurvy among the sailors of our mercantile marine—an important one being that owing to the great increase in the number of steamships employed in our purely mercantile trade, the character of the sailing vessels, which as a class alone furnish cases of scurvy, have considerably deteriorated. The owners are too frequently merely speculative adventurers, and the crew as often the dregs of the port, who have been unable to secure employment in the leading lines. Another point is that some owners of vessels place too much reliance on lime-juice, to the neglect of varied food scales. When the voyage is a protracted one, in addition to the daily issue

of lime-juice, fresh messes should be served out at least twice a week. This is a precaution but rarely observed in the class of vessels we have alluded to. A great deficiency in the Merchant Shipping Acts is that they do not in any way prescribe the quantity or sort of food to be supplied to seamen on board British merchant ships, the food scale being a matter of contract between the master and the seaman for each voyage. This ought not to be permitted, and the sailor should be protected from any shortcomings to which his ignorance or the rapacity of the ship-owner may expose him. Dr. SPOONER, of Liverpool, at the instance of the Board of Trade, has drawn up an improved victualling scale of the provisions to be served out to a crew per day, in addition to the issue of lime-juice and sugar, and which might be advantageously made compulsory on all ship-owners. Dr. SPOONER gives preserved fresh meats three days a week, salt pork and salt beef two days in the week respectively, two ounces of preserved potatoes four times a week, eight ounces of preserved carrots three times a week, besides one pound of marmalade and four ounces of pickles weekly. This is the most rational dietary, that can be obtained under the circumstances, and places the sailor under nearly as favourable dietetic conditions as the soldier; certainly, as far as the alkaline bases—the withdrawal of which is supposed to be one of the chief factors in the production of scurvy—are concerned. With regard to this point, it is interesting to quote the results obtained by Dr. RALFE in the comparison of the composition of the sailor's and soldier's diet respectively. He found that, whilst the total inorganic constituents of the sailor's diet exceeded those of the soldier's, the actual alkalinity of the ash was nearly half that yielded by the soldier's food.

THE insanitary condition of the Melbourne Hospital, and the marked prevalence of septic diseases among the surgical patients, have lately excited so much attention in the colony that a committee was appointed by the Board of Management to inquire into and report upon the best means of improving the sanitary condition of the hospital, either by removing the site, by reconstructing portions of the present buildings, or otherwise. The committee appears to have conducted its investigation with great care, and examined a large number of witnesses. Their report, which has been formally endorsed by the Board of Management, is now before us in the pages of the *Australian Medical Journal*. The committee rejects the proposal to move the hospital to another site as unnecessary, and, at any rate, premature. It sketches several important structural alterations which should be made "whenever funds are available." Then follows the important part of the report, to which we wish to draw attention. It may be summarised in these two quotations:—"An examination of the evidence tendered by the witnesses, and of that extracted from recent medical works which have been laid before the Committee, convinces that body that the lamentably high rate of mortality in cases of surgical fever.....is traceable beyond doubt, to the imperfect adoption of a strictly antiseptic treatment, on Mr. LISTER'S principles, of surgical cases." "The Committee trust that this important subject will receive the early and serious consideration of the honorary staff. The splendid results which have attended the treatment of

ovariotomy in this hospital, and of all kinds of surgical wounds and injuries in the hospitals of Europe, convince the Committee that in the general and faithful introduction of Listerian antiseptics, the Committee of Management may look with confidence to a great saving of life in the hospital, and to the lasting riddance of erysipelas and blood-poisoning generally." One piece of evidence which evidently had considerable weight with the Committee is the following:—"Until strict antiseptic precautions were taken in performing operations for ovariotomy every case terminated fatally; but since the introduction of strict antiseptic treatment, there have been thirteen consecutive operations by two surgeons without a single death."

In thus suggesting to the medical staff the best treatment to pursue, the Committee have taken a step of which we cannot approve in principle. Laymen are not capable of judging accurately of the value of therapeutical means, and medical men may fairly demand perfect liberty of action in this respect. No body of honourable men would serve in a hospital if they were to be hampered and restricted in their treatment by a committee of laymen. It is easy to see what disastrous results would of necessity ensue, were such interference tolerated. But not even this sound principle is safely pushed to extreme limits. There are cases in which a lay committee may rightly interfere, and is in duty bound to do so. If lives are sacrificed in obedience to some prejudice and in direct defiance of well-established scientific facts, the authorities of a hospital, who are responsible for its proper management, have an undoubted right to interpose. And the real question in this case comes to be, whether the facts on which Mr. LISTER'S treatment are founded, and its results, are so well established and so undoubted, that they may be fairly judged of by a body of laymen. We are aware that many eminent surgeons of our own country would state that they are not, and that an investigation of them by the lay committee of a hospital is *ultra vires*. But, whatever views we may hold on that subject, we must not lose sight of the really practical point, which is, that any committee appointed to consider in what way the sanitary condition of a surgical hospital in which septic diseases are rife may be improved is bound to investigate the results of the aseptic treatment. And with the evidence on this subject which can now be adduced, to what result can such an investigation, if impartial, lead, than that this plan is the only really trustworthy one for abolishing septic disease? The most approved hospital construction, the most ample ventilation, the greatest care in the selection of cases, and other modes of dressing carefully carried out, have been able greatly to reduce the prevalence of septic disease; but aseptic surgery, or Listerism alone and by itself, has, in every instance in which it has been faithfully followed out, succeeded in abolishing all septic diseases. Facts are stubborn things, and this statement does not go beyond the facts. So strong is the case for aseptic surgery, that any surgeon who has to combat septic diseases is without excuse if he neglect to avail himself of it. Surgeons must then be beforehand with their committees. It is for them to be fully acquainted with every advance of their art, and on the alert to adopt any well-planned and successful improvement. In all matters of hospital sanitation committees of management should

receive the initiative from the staff. If this question has arisen in the Antipodes to-day, to-morrow it may crop up in this country, and it behoves any surgeon to possess himself of the most authentic facts, and to act upon the knowledge so gained. We therefore rather regret the necessity for the decision of the Committee, than disapprove of the actual report adopted.

We trust that whatever feelings this report may have awakened—and of this we know nothing—the staff will see to it that the aseptic treatment is given the fairest possible chance. It is their manifest duty to carry it out in full detail with the utmost precision, and we cannot believe that there will be any backwardness in doing this. The alternative is to incur a responsibility which no conscientious man would willingly bear.

## Annotations.

"No quid nimis."

### THE MEDICAL STAFF IN EGYPT.

THE officers whose names we published last week, as being likely to form the administrative medical staff of the troops sent to Egypt, have received their appointments; and we are glad to observe that the Principal Medical Officer, Mr. Hanbury, is to have the local rank of Surgeon-General. An important addition has been made to the staff, in accordance with the principles laid down in the Report of Lord Herbert's Commission, by the appointment of a Sanitary Officer to the force; and for this responsible post Brigade Surgeon J. Marston has been selected, with the local rank of Deputy Surgeon-General. We believe that it would be impossible to find an officer so well qualified in every respect for this special service. Dr. Marston possesses a thorough knowledge of the principles of sanitary science. He had several years of official experience at the Army Medical Board during the time when the sanitary branch was being more fully developed. He has since passed four years in India at the head-quarters of the Army, and upon him devolved the principal part of the duty of laying down the sanitary rules for the European force which served with so much distinction in Afghanistan. The papers which he drew up for the Principal Medical Officer's report on the subject of Enteric Fever in India afford unmistakable evidence of high powers of investigation and of an intimate knowledge of the subject of which he treated. He has also shown himself well qualified for the not unfrequently very difficult task of working harmoniously with the officers of his own and other departments with whom in the course of duty he may be brought in contact. The selection of the officers for the administrative posts of the Medical Service in Egypt reflects great credit upon the new Director-General, and may, we trust, be taken as foreshadowing the manner in which the Department will be conducted during his period of office.

Eight field hospitals are to be sent out with the force, each provided with camp equipment, stores, &c., for 200 beds. The staff will consist of a brigade surgeon or senior surgeon-major in charge, six executive medical officers, one quartermaster, and the requisite Army Hospital Corps establishment for each hospital. It is intended also to form two general hospitals, one at Cyprus for 400 sick, and the other at Malta for 200 sick and wounded. These will, of course, be provided with the requisite staff and equipment. Two hospital ships are being fitted out to accommodate about a hundred sick each, with staff and every requisite, and it is hoped they will be ready to accom-

pany the expedition. So far as we have been able to learn, the preparations of the Medical Department appear to have been well considered and promptly carried out, and there seems every reason to hope that nothing will be wanting to ensure the comfort and well-being of the sick and wounded on the present occasion. The first field hospital (stationary) left Portsmouth on Thursday, the 27th, in the s.s. *Dacca*. The hospital is equipped with beds and material for 200 patients, water carts, pharmacy waggons, and light ambulances accompanying it. Three ice machines are being despatched to Egypt for the use of the hospitals. It is expected that the second field hospital and 1st Bearer Company will embark in a few days.

#### THE THAMES POLLUTION COMMISSION.

THE Royal Commission recently appointed to inquire into the fouling of the Thames by the sewage of London is already at work. Several witnesses have been examined, and others will be called before the adjournment which will ere long be necessary. We are heartily glad to hear that the Corporation of London intend to take into their own hands the defence of their river. They saved Epping Forest; now let them save the Thames, and they will a second time earn public gratitude. The tenacity with which the Metropolitan Board of Works cling to the filthy pollution over which they preside is quite remarkable. But, though powerful, they are not omnipotent; and if the City really exerts itself, they are, we think, sure to have to submit. We will not at the present time enter into the scientific and social questions involved, but will content ourselves with once more reminding our readers of the gravity of the nuisance. Few persons know how bad it is. Let anyone who doubts take a boat to Barking Creek during ebb tide, and watch and smell the foul stream of mixed solids and fluids which pours from the outfall. No filtration of any kind is attempted, and we believe that none would be successful. People often talk as though London sewage was a more or less clear liquid. Let them go to Barking—that is all we ask. Let them remember, moreover, that the sewage which falls into the river towards the end of the ebb is carried by the flood tide up the river far beyond the outfall.

#### SUMMER AT LAST.

It is confessedly rash to hazard a word of congratulation on the momentarily seeming arrival of summer at last. Before anything we may now write can reach our readers it may be wholly falsified by the vicissitudes of a climate which must emphatically be described as one of ceaseless change. We seldom have two days alike, or even a day which is seasonable throughout. Whatever the meteorologists may have to say on the subject, it is a matter of fact and experience that the weather was not as variable forty or fifty years ago as it is now. During the winter which has just passed—if, indeed, we can be said to have had any winter—there was not a single snowstorm in London; and up to the present week neither spring nor summer has produced a day wholly characteristic. We do not sufficiently recognise the part this changeable element in the climate of England plays in the production of the many ailments to which its inhabitants are exposed. The public records of death from assigned causes throw little light and have no direct bearing on the multitude of minor illnesses from which people do not die, but by reason of which their lives are often made extremely miserable. The surprisingly large increase in the comparative frequency of troubles affecting the mental and nervous system of late years is doubtless in large measure due to the incessant and almost instantaneous changes which take place in temperature, atmospheric pressure, and hygrometric and

electric conditions. These variations call for a power of resistance in the organism which is not so commonly found as it used to be when the habits of life were less exacting to what may be termed the *sensibilities*. Culture and civilisation, with the aid of wondrously contrived appliances of a luxurious life, have rendered us more “delicate” in our feelings, sympathies, and constitutions than we used to be. A very small and rapidly decreasing class of the population can be now characterised as robust. Refinement has, so to say, fined us down, and made us more susceptible of external influences than our grandfathers and grandmothers. It is, therefore, only natural that affections which are the result of impressions produced through the senses, or more directly on the nervous system, should increase, and that “feelings” should play a peculiarly prominent, and actually important, part in the formulation of disease. It is not, of course, possible to eliminate this element from the evil with which we have professionally to deal; but it is well that its existence should be recognised. Probably there never was a time when simple vaso-motor disturbances were so common, so seemingly causeless, and yet so mischief-making as now. It may be worth while to devote more attention to this particular trouble than we are wont to bestow on it. It is quite within the range of physiological probability that even grave pathological changes may take their rise in small, and apparently unimportant, departures from the normal habits of organic life.

#### VACCINATION IN SCOTLAND.

WHENEVER the protective power of vaccination is discussed we are liable to have Scotland pointed to as an example of what good results may be brought about by an intelligent and loyal people's faithful submission to the vaccination laws. As was recently shown by Dr. Carpenter, the proportion of unvaccinated people in Scotland must now be exceedingly small. The mortality from small-pox has been of late scarcely appreciable, prosecutions under the Compulsory Vaccination Acts are almost unknown, and it is likely that the northern portion of the kingdom will be able to guard itself in the future against such an epidemic as occurred in 1870 and the immediately succeeding years. Even the few fatal cases which have of late been recorded were—at least in several instances—direct importations from London or the Continent; the patients arriving either as sailors or tourists, with the disease fully developed. Small-pox may therefore be considered as stamped out of Scotland for the past few years, and it would appear unnecessary to do more than congratulate the authorities and the profession upon the success of their measures. We are not sure, however, that a word of warning is not more appropriate. There are several particulars regarding both the law and the practice in which Scotland is certainly behind her southern sister, and these imperfections are so marked that attempts at their removal would be more satisfactory than the present complacency. In the first place no child need be vaccinated before it is six months old—as a matter of fact the vast majority remain unvaccinated till close upon this period,—many escape altogether through removal from the registrar's district, and the system of inspection, or the authority of local administrators, is so lax that a large number of the children are unvaccinated till they reach the age of nine to twelve months. By allowing the child to reach the period when teething occurs and skin eruptions are apt to appear, risks are added which often give rise to a prejudice against either vaccination or the vaccinator, and which need not otherwise be run. The inspection of vaccination results is much less attended to than in England, and the absence of Government grants for special success is much felt, as well as the gratuitous service so often necessary when the fees must be paid either by the

patients or by the parochial boards—the latter in the case of paupers only. It may also be remarked that at present there is no Scottish source of supply for calf-lymph; and it is well known how the probability of success with this is diminished by its being stored for a length of time before use. In truth the lymph in general use is thoroughly humanised, and if to this is added the equally notorious fact that the vast majority of children are vaccinated in but two places—many have but one satisfactory mark,—we have reason to fear that any considerable outbreak would prove that the Scottish people had been but living in a fool's paradise. Parents, especially among the working classes, invariably regard one or two marks as sufficient, and under the present system no inducement is offered to the medical man to insist upon more. It might not be advisable to institute any considerable change, and we are not sure that the appointment of public vaccinators, as in England, would be acceptable to the profession; but a Government supply of lymph might be offered, more systematic and close inspection instituted, and payment by results established. Effectual protection in the face of a virulent epidemic cannot be anticipated unless the vaccination is not only as regularly, but much more thoroughly, performed than it is at present.

#### RECOVERY FROM RABIES.

ON more than one ground the possibility of the recovery of dogs from attacks of rabies is of great importance. The demonstration that this terrible disease is not invariably fatal, even in the animals most prone to it, may at least be welcomed as affording a ray of hope for therapeutics, while the fact of the recovery of affected animals may afford an explanation of many mysterious outbreaks of the disease. M. Decroix lately communicated to the Académie de Médecine nine cases which he had collected of well-authenticated recovery from rabies. (1) M. Ménecier inoculated two dogs and a rabbit with the saliva of a rabid dog; all three died from rabies, but the dog from which the saliva was obtained recovered. (2) Decroix inoculated a dog with the saliva of one suffering from rabies; the latter died, the former became affected with characteristic rabies and recovered. (3) Some saliva was obtained from a man some hours before he died from hydrophobia, and with it a dog was inoculated; the animal presented well-marked symptoms, but recovered. (4) Reg of Lyons recorded the recovery of a dog with furious rabies, due to a bite from another rabid animal. (5) A military veterinary surgeon, Laquerrière, has recorded the case of a dog affected in consequence of a bite from an animal unquestionably rabid. The destruction of the dog was ordered, but the owner refused to consent and the dog recovered without treatment. The four remaining cases were of recovery from rabies, in man in three cases, and in the horse in the last. Decroix points out that in furious rabies the attacks increase in frequency and intensity during two or three days, then attain their maximum, and disappear in two or three days more, whereas death does not occur until the fifth or sixth day. The eminent authorities who have never met with an instance of recovery are scarcely justified in denying the occurrence of such cases described by those practitioners who have seen them. The Rabies Committee, of which M. Decroix was president, has made, since 1874, a host of experiments with various substances of reputed value in rabies, three of them with pilocarpine, and every supposed remedy which they employed appeared actually to hasten death by the violent paroxysms which it caused. The conclusions of M. Decroix are that it is experimentally demonstrated that rabies may terminate in spontaneous recovery. Up to the present day no agent has made good its claim as a remedy for rabies. The cases of recovery attributed to this or that agent may be,

with equal justice, ascribed to the spontaneous termination of the disease. The dogs which recovered in the experiments carried on by the committee were left at rest, and, since the administration of medicines usually provokes convulsive seizures, it seems desirable, according to our present knowledge, to leave persons affected with hydrophobia in the most perfect possible calm, trying experiments only upon animals. In absolute quietude and obscurity the paroxysms are far less terrible than when medicines are administered, and M. Decroix asserts that if these conditions could be secured, he would far rather suffer from hydrophobia than from many other diseases. It may, however, be observed that we are scarcely justified in drawing, from the superior results of therapeutic inactivity in dogs, the same lesson in the case of the disease in man. The administration of a drug to the human sufferer by the skin or rectum, or sometimes even by the mouth, may be effected with far less disturbance than in the case of the dog. Without doubt, however, he is correct in insisting on the absolute importance of perfect tranquillity, and of the avoidance of everything which may in any degree help to excite the paroxysms. It may be doubted also whether dogs are the best subjects for therapeutic experiments, since it is probable that the conditions met with in the human subject obtain more closely in the herbivora than in the carnivora. It is very desirable, in the case of any recovery from rabies, that it should be ascertained at what date the saliva ceases to be infectious, and whether the disease can be communicated after the animal has to all appearance recovered. This is a not improbable explanation of the occasional alleged occurrence of the disease from the bite of healthy animals.

#### PROF. CRUM-BROWN ON RIVER POLLUTION.

IN connexion with an action now pending in the Court of Session, with regard to the pollution of the rivers Gala and Tweed, by the manufacturers of Galashiels, a very interesting report has been presented by Professor Crum-Brown of Edinburgh. The document is a lengthy one, and the following is but a brief abstract, more especially of Dr. Crum-Brown's conclusions. He finds that at some of the mills there is no dyeing, but in most of them the common discharge is exhausted dye liquor and soapy liquid from wool, piece, and yarn scouring. At the mills where there is no dyeing the discharge is simply soapy liquid from scouring. In the various works some or all of the following methods for the prevention of pollution are at work—(a) The soapy liquid is used over again for scouring, after the removal of solid matter in suspension by settling in tanks. (b) Wood chips, &c., are to a very great extent caught in metal screens perforated with small holes. (c) Settling ponds, of varying size and number, are in use, through which the mixed liquids flow before entering the Gala. (d) The chemical treatment in greatest use consists of the application of the "Magma process" to the soapy waste. It will thus be seen that it is the residual soluble substance which most requires to be dealt with, as, notwithstanding the "Magma" process, fatty and oily acids, soluble nitrogenous and animal matter, and free sulphuric acid are found in the effluent water. Dr. Brown states that these may be completely removed by the use in the proper proportion of the following four substances—Lime-water, sulphate of iron, sulphate of alumina, and sulphuric acid. It may appear at first strange that I should recommend the use of four substances, no one of which could be put into the stream without injury; but these substances act so on the polluting matters in the discharge from the mills and on each other, that these polluting matters and the great part of the added chemicals are precipitated as a sludge which can be removed by settlement and filtration, leaving in the effluent water very little from the impurities, and nothing from the added chemicals except some sulphate of

soda and sulphate of lime, substances which occur in most natural waters, and which cannot, in the quantities thus produced, be considered injurious to the water." For economic reasons, Dr. Brown recommends that the various proprietors should carry out a conjoint scheme for the purification of their refuse water. Several of these measures are in use where sewage only is the cause of the pollution; and the whole report should be carefully read by anyone interested in river pollution, from whatever source arising.

#### FRANK MAITLAND BALFOUR.

THE daily press contained on the 24th inst. a brief notice of the death of a man who can ill be spared at the present time. Mr. Frank Maitland Balfour was killed by a fall in the Alps, but no particulars appear to have been obtained save the fact that his body, along with that of his Swiss guide, have been discovered on the Italian side of Mont Blanc. It is only a few months ago that Mr. Balfour was elected Professor of Animal Morphology at Cambridge, after having passed through a distinguished University career; and it will be difficult to supply his place. His treatise on Embryology, together with his previous work on that subject, placed him in the front rank of investigators in that very special and difficult line of research. If his life had been spared there can be no doubt he would have added largely to our present knowledge of many points that still remain obscure. He was placed second in the first class in the National Science Tripos, in 1873 graduated B.A., and proceeded in due course to M.A. He was elected to the Fellowship at Trinity, was Royal Medalist in 1881, and President of the Cambridge Physiological Society. He was hon. LL.D. of Glasgow and a Fellow of the Royal Society. He was a younger brother of Mr. Arthur Balfour, the Member for Hertford, and nephew of the Marquis of Salisbury. His age was a little over thirty years.

#### PURIFIED TOW FOR ANTISEPTIC DRESSINGS.

MM. WEBER and THOMAS, of the French army, assert that the desiderata of an antiseptic dressing for military surgeons are—(1) absolute purity; (2) perfect whiteness and cleanness; (3) elasticity, smoothness, and softness; (4) great absorbent power, both of secretions from wounds and of antiseptic agents; it should (5) efficiently filter the air; (6) be antiseptic; and (7) cheap. They assert that they have prepared some purified tow which answers all these requirements thoroughly. Commercial tow is dirty, harsh from the presence of much woody fibre, and non-absorbent. This commercial tow is first dusted and tied tolerably firmly in packets, which are then soaked in water for twenty-four hours; they are then wrung out and placed in cast-iron pans, and a solution of caustic soda is poured on and kept just boiling for half an hour. The tow is then put into cold water and repeatedly washed until it has no action on turmeric paper. Subsequently it is immersed for half an hour in a solution of hypochlorite of soda, and again washed in cold water as before. After soaking for twenty-four hours in cold water the latter is pressed out and the tow is plunged into dilute hydrochloric acid and left for half an hour, after which it is again washed in water and allowed to soak for twenty-four hours and then dried, after which it is carded in sheets or pledgets, or combed. Tow thus prepared is stated to be chemically pure, of perfect whiteness, soft, very elastic, readily absorbent, easily impregnable with antiseptics, and cheap. To render it thoroughly aseptic it may be impregnated with either carbolic acid or iodine. For the former a solution of three parts of the acid in two parts of alcohol is sprinkled on sheets of filter paper, and these are laid between sheets of the tow and placed in a

closed box. At the end of forty-eight hours the acid has all passed into the tow, in which it can be demonstrated under a microscope in the form of minute drops. MM. Weber and Thomas have prepared the carbolised tow of a strength of ten per cent., which they state to be an unirritating dressing and more than sufficiently strong of the acid for surgical purposes. To impregnate the tow with iodine they expose it to the vapour until it assumes the colour of roasted coffee. By similar means creasote, eucalyptus, &c., may be added to the tow. They state that, prepared in moderate quantities, the purified tow costs  $1\frac{1}{2}$  fr. to  $1\frac{3}{4}$  fr. per kilo, or when carbolised 2 fr. to  $2\frac{1}{2}$  fr. per kilo.

#### SEWAGE, STORM-WATER, AND THE VENTILATION OF SEWERS.

IT is only natural, but it seems strange, to find precisely the same questions cropping up and being discussed upon the same lines and with very nearly the same detailed arguments which were rife five-and-thirty years ago. History repeats itself, in regard to social and domestic matters, at recurrent periods of about thirty or forty years, probably because that is something like the lifetime of a generation. However this may be, it is certain that those interested in sewerage were discussing the need and policy of separating storm-water from the sewage at the date to which we have alluded; and it is within recollection that the same opinions and allegations were used then as now. The chief difference is as to the amount of the extraneous water introduced into the sewers. Thirty years ago the supply of water for domestic purposes was less per head of the population than it is now; and it may be assumed that the total dilution of the sewage is greater than it used to be. This is the real difficulty as regards all systems of sewerage. It would be comparatively easy to dispose of the semi-solid material if only such quantities of water were added as might be required to flush the drains. We are glad to see that the sewerage of Slough, Bucks, has been reconstructed on the fundamental principle of keeping the surface and storm water apart. Although this question has come to be regarded chiefly in relation to the utilisation of sewage, it is really one of practical drainage, and ought to be so treated. We are also gratified to find that the system of ventilation by shafts is beginning to receive the attention it deserves. The Sanitary Committee of Paddington district has the subject under notice, and is preparing to take action. We trust there will be no mistake as to the lamp-post scheme. Unless provision can be made for actually destroying the sewer-gas in the flame of the gas used for lighting purposes, as was proposed in America some years ago, it is not practicable to use the lamp-posts as ventilating shafts, however large the calibre of the pipes may be. Pipes affording a way of escape for the sewer-gas must needs be carried above the roofs of the houses, or it will simply poison the atmosphere at a high level, instead of rendering the air breathed by the population pure.

#### THE HOSPITAL SATURDAY FUND.

WE are glad to see notices of efforts to make the Hospital Saturday Fund more worthy of the working classes, on the one hand, and of the hospitals on the other. The most certain way of securing this is to realise that hitherto the result of the collection has been altogether inadequate. Mr. E. R. Cook, presiding at a meeting in Lamehouse, said he saw no reason why the Fund should not reach £20,000 as against £8,500. To this end co-operation and organisation are necessary. What is above all necessary, it seems to us, is to organise a plan by which a working man could be induced to set apart a certain sum weekly for some time before the collection for this purpose.

## TUBERCLE OF THE SYNOVIAL SHEATHS OF TENDONS.

MM. TERRIER and VERCHÈRE describe a tubercular disease of the synovial sheaths of tendons, which appears to be more common in the hand than any other part. The tubercular nature of the affection in the cases they report is demonstrated by the microscopical characters of the inflammatory growth and the concomitance of tubercular disease of the lungs. Premising that the disease may be secondary to tubercular affection of neighbouring bones and joints, they draw special attention to the form which occurs primarily in the synovial sheaths. They describe the origin of the affection as insidious, and the progress as very chronic. The first symptom is a swelling over part of a synovial sheath, as for example over the palmar surface of a phalanx. This swelling gradually grows and becomes softer, movement of the part then becomes both painful and limited. Other like swellings appear over other portions of the synovial membrane, as in the palm of the hand and above the wrist. The skin becomes adherent, reddened, and ultimately ulcerates, and pus and sero-pus are discharged; the ulcer extends, its edge being irregular, thin, undermined, and livid. A probe passed to the bottom of the ulcer readily finds a narrow opening into the sheath, along which it may be passed for some distance. The tendons do not slough, nor do they become firmly adherent. The disease does not spread to the neighbouring bones and joints; and although in its course more than one part of the synovial membrane is affected, these are separated by quite healthy portions of the membrane, and this fact forms one of the best diagnostic features by which it may be distinguished from fungous disease of the membrane, in which the whole extent of the sheath is always involved. In one of the two cases observed by the authors there was a very distinct history of an injury as the exciting cause: the patient, a young woman, had cut her wrist severely, and in another case there was a history of a bruise. The constant and rapid movements of the hand are considered to account for the great frequency of the disease there. The only treatment which promises any good seems to be early free removal of the tumours; cases in which this was done with good effect by Trélat and by Bouilly are recorded in the paper before us in the July number of the *Revue de Chirurgie*.

## SMALL-POX AND MILK CARRIERS.

A CASE has come to light in Poplar which illustrates in a forcible manner a method by which small-pox may be spread through a community by the agency of milk. Four patients suffering from that disease were found in a dirty and deplorable condition in the house of a man who was employed in delivering milk. The disease had already prevailed for about five weeks, and the man, presumably in order that he might not be hindered from following his occupation, had avoided calling in any medical practitioner. During the whole of that period he had been in constant work, the fact of small-pox existing in his family being kept from his employer. Had a system for the compulsory notification of infectious diseases either by the occupier alone, or by the occupier and any medical practitioner, been in operation, the milkman could have been punished for having failed to comply with that provision. Whether he can be punished or not under the Dairies, Cowsheds, and Milkshops' Order, 1879, is somewhat doubtful. The order provides for the punishment of any cowkeeper, dairyman, purveyor of milk, or occupier of a milk store or milk shop, who has anything to do with the milking of cows, or the production, distribution, and storage of milk, if he have either suffered from or come into contact with infection, or for employing anyone thus liable to convey infection. But, in this instance, it is

not clear whether the man delivering the milk can be deemed as coming within the definitions quoted, and it is certain that his employer had no grounds for suspending him from work. The Sanitary Committee have referred the case to their clerk to see whether a prosecution can be sustained against the milk carrier.

## DEATH FROM CHLOROFORM.

MR. F. E. CANE, L.R.C.P. Ed., acting house-surgeon to the Bradford Infirmary, forwards to us the subjoined account of a death following the administration of chloroform at that institution:—

"George F—, aged fourteen, was admitted into the Bradford Infirmary on Wednesday, the 12th inst., suffering from the ordinary dislocation of both bones backward at the elbow, with fracture of the coronoid process. I saw him ten minutes after admission, and found him pale and trembling. He cried and asked me not to hurt him. On manipulating to ascertain the injury, he writhed and screamed so much that I considered it better to let him rest for some time to recover from the shock, and told him I would give him chloroform to lessen the pain. I accordingly went away, and returned in about twenty minutes. Finding him somewhat recovered, and considering his age in his favour, I asked Mr. W. J. Spence, resident dispensary surgeon, to administer the anæsthetic. His heart was examined and found normal, but slightly weak. He had had no food since his breakfast, which was light. The drug was administered by means of a simple inhaler, and the total quantity given at a time was one drachm and a half. The patient took it well, pulse and respiration remaining satisfactory. In about five minutes he seemed fairly under its influence, and I reduced the dislocation rapidly without trouble. The boy groaned and kicked as this was being done, and from that time no more chloroform was administered. The arm was put up in angular splints and bandaged. On the completion of the bandaging, the patient, who was spitting and beginning to recover, slightly raised his head from the sofa on which he was lying. In about ten minutes after this his breathing was prolonged and slow, and I noticed his face become deadly pale. I placed my hand over his heart, and could not perceive any impulse. I drew forward his jaw, and he took a full inspiration, the chest wall expanding. Mr. H. Meade, one of the honorary visiting surgeons, was in an adjoining room, and I had him promptly in attendance. The tongue was drawn forward with an artery forceps, cold water was dashed on the face and chest, the head was lowered still further, Silvester's artificial respirator was used, a strong battery applied, and ammonia held to the nostrils. All these means failed to restore the boy, who died about ten minutes after the chloroform had ceased to be administered, and about two minutes after the first symptoms were noticed. Artificial respiration was of course kept up for some time. An inquest was held, and a verdict returned in accordance with the medical testimony, the coroner not considering a post-mortem examination necessary."

## NOTIFICATION OF DISEASE IN GREENOCK.

A DISCUSSION on the question of notification of disease in the Police Board, Greenock, gave occasion to Mr. McNaught to express some strange views of the duties of medical officers of health and of economy in public bodies. A Bill was under the notice of the Board, including a clause requiring, as we understand, a notification of infectious disease both by the householder and the doctor. Mr. McNaught was against the system of notification, and argued that it would operate so as to discourage the people from consulting a doctor in cases known to be infectious. But what we wish to note is his remarkable views of the duties of medical officers of health. "There was one thing

he should like to see in the Bill, and that was that the public health medical officer of this town should be prohibited from attending cases in the surgical wards of hospitals while infectious cases were under his care and treatment, and he thought he should attend all the infectious cases sent to the infirmary as being part of his duties, and thereby save about £50 a year to the Board. He did not think military hospitals would put up with the same treatment for a single day.” What an autocrat Mr. McNaught must be, to think of dictating the conditions under which a medical officer of health should treat surgical diseases, and to require such officer to attend all the infectious cases sent to the infirmary *as part of his duties*, and thereby save the ratepayers about £50 a year!

#### LIGATURE OF THE INNOMINATE.

MR. WILLIAM THOMSON, of Dublin, favours us with an account of the termination of his case of ligature of the arteria innominata. “My patient,” he says, “died on the 20th inst., the forty-second day after ligature of the innominate. There was no recurrence of bleeding after the thirty-ninth day. The sinus was found to terminate in an ulcer, which involved the anterior wall of the junction of the subclavian, carotid, and innominate arteries. The innominate and carotid arteries were filled with clot; the subclavian contained a clot occluding it to the extent of half an inch. The position of the ulcer was on the distal side of the ligature, the constricted portion of the innominate not being involved. The hæmorrhage had apparently taken place from the innominate, as there was a recent blood stain on the cardiac side of the clot. None of the vessels were pervious to water forced in with a syringe. The aorta was atheromatous. Consolidation was proceeding satisfactorily in the tumour. This is the second longest survival (except Smyth’s case, which recovered) on record; Graefe’s case having reached the sixty-seventh day, and Cooper’s the thirty-fourth.”

#### REGISTRATION OF DEATHS ACT, 1874: NEW AND IMPORTANT DECISION.

ON Tuesday, July 11th, at the Lambeth Police Court, before Mr. Chance, Charles Frederick Groom, M.R.C.S.E., was summoned at the instance of the Medical Alliance Association for wilfully making a false certificate, under or for the purposes of the Births and Deaths Registration Act, 1874, concerning the death of a child, named Mary Louise Sparks, on June 28th, 1882. Mr. C. J. C. Pridham, Solicitor to the Association, appeared for the prosecution, Mr. Mayo defended. It was proved at the hearing that the defendant had seen the child once and had made up a bottle of medicine for it. Mr. Chance, however, held that one solitary attendance did not amount to that degree of investigation and attendance of the patient’s case which would justify the defendant in giving the usual form of death certificate under or for the purposes of the Act, which he had done. He therefore convicted the defendant of the offence charged, and fined him £2 and £2 2s. costs.

#### GASTROSTOMY.

ON Thursday, the 20th inst., at the Wolverhampton and Staffordshire General Hospital, Mr. Vincent Jackson performed the operation of gastrostomy. The patient, a middle-aged man, was suffering from cancer of the cardiac end of the œsophagus, and, in the opinion of Dr. Totherick, was fast sinking from starvation. The operation was divided into two stages, and on the fifth day after the first operation the stomach was linearly excised. Since he has been fed by the stomach and rectum, and everything is favourable. A full report of the case will shortly be published.

#### FATTY TUMOURS OF THE PALM OF THE HAND.

LIPOMA of the palm is an infrequent but important affection. The diagnosis is attended with difficulty, for the tumours are often fluctuating; and in this, as well as their slow and painless growth and rounded outline, and the fact that they sometimes extend under the annular ligament, they resemble cysts of the synovial sheaths. When punctured, however, they do not yield fluid, but, on the contrary, a small pellet of fat may be extruded, which makes the diagnosis certain. The treatment is excision; but this should not be lightly undertaken, as in the palm these tumours do not grow from the subcutaneous fatty tissue, but from the fat under the deep fascia or between the muscles. Indeed, it has been suggested that in some cases they are developed from processes of the synovial sheaths of the flexor tendons, and are comparable with the arborescent lipoma of the synovial membrane of the knee described by Billroth. Great care must be taken to secure union of the wound by first intention, or the apparently simple operation may be followed by extensive suppuration in the palm and adhesion of the flexor tendons, with the result of a more or less useless member.

#### “AN ODD EPIDEMIC.”

A CORRESPONDENT in Norfolk draws our attention to what he terms “an odd epidemic” which has attacked a large number of his patients during the spring and early summer of this year. The affection has commenced with considerable prostration, nausea, and giddiness, accompanied with a state of nervous alarm and depression amounting almost to melancholia. The temperature has been normal, the pulse 100, soft, and the skin moist. After a day or two material improvement has taken place, and then within a week a relapse has occurred, at times accompanied by coryza, partial occlusion of the bronchial tubes, with clear, starchy mucus, the formation of sensitive sores about the margins of the nostrils, mouth, &c., pain in the intercostal muscles and the joints, loud buzzing sounds in the head, extreme sensitiveness of the scalp, and even cephalalgia. In some cases several relapses have occurred, the intervals of improvement increasing in duration as the affection gradually subsided. We are informed that groups of cases have been met with not only in Norfolk, but in Warwickshire and in London. If so, a brief reference to them, and, above all, a record of the circumstances with which they have been associated will be of interest.

#### SYPHILIS CONVEYED BY SKIN-GRAFTS.

ANOTHER case in which syphilis was conveyed by skin-grafts is reported in Paris by M. Féréol. It occurred in the practice of M. Deubel; the patient was a man, aged forty-nine, who had not had any venereal affection, and who had a large wound caused by erysipelas with sloughing. Seventy-five dermo-epidermic grafts were put on, nearly all of which “took” and cicatrization was rapidly effected. A month after the application of the first grafts the cicatrix began to ulcerate in several places. Six weeks later an abundant roseolous eruption broke out over the body, and a month later mucous patches appeared in the mouth. One of the sons of the man, who had furnished grafts on each occasion, then consulted M. Deubel for mucous patches about the anus, and stated that eighteen months previously he had had a hard chancre for which he had not had any treatment. The case is apparently beyond all doubt, and shows the necessity for caution in the selection of persons from whom grafts are taken. The safest rule to follow is, wherever possible, to take the grafts from the person on whom they are to be implanted.

## ROYAL UNITED HOSPITAL, BATH.

WE have received a copy of the Registrar's report of the Royal United Hospital, Bath, for the year 1881. It is very brief, but bears evidence to the amount of work done at this old-established hospital. The Registrar (Mr. Hopkins) has also made out a table of all the operations performed in the hospital since 1849, which may prove useful as a standard of comparison with the results obtained at the present day. Short notes of four deaths occurring from the administration of anæsthetics during the same period are also given. In one case the anæsthetic used was bichloride of methylene, and the patient, a man aged fifty, died when only a drachm had been given. In the other three cases chloroform was the agent. In one case the death resulted from shock, the operation having been commenced before anæsthesia was obtained. The report closes with notes on the museum, which was a pet of the late Mr. Gore, and nearly all the specimens in it were contributed by him. It contains many specimens of great interest, and it is to be hoped that it will be continually enriched by the addition of specimens which are always to be obtained at any large hospital.

## MINERS' DISEASES.

THE morbid states, other than those of the lungs, which are produced in miners by the coal-dust to which they are exposed, have been recently studied by Dr. Fabre, of Commeny. He does not believe that the dust has any special action on the skin. The impetigo and eczema common among miners, and attributed by some authors to the influence of the dust, are not, he believes, due to this cause, but to the influence of water in the workings containing, dissolved, some irritant substance. These eruptions are never met with in the workers in coal at the surface, who are equally exposed to the influence of the dust. Almost all miners present characteristic bluish cicatrices, indelible as tattoo marks, which result from any wound produced by a fragment of coal. The dust in the air occasionally causes a certain amount of simple conjunctivitis, and very often true keratitis, sometimes accompanied by iritis, and frequently leading to ulceration of the cornea. These are due to the implantation in the cornea of small fragments of coal. Deafness is also common, and is due to a hard plug, composed of cerumen and coal-dust, in the external meatus, usually accompanied by some inflammation of the lining membrane.

AMONG the appointments that have recently been announced as having been made in the medical department of the University of the City of New York are the following:—Dr. William H. Thomson, Professor of Diseases of the Nervous System (in addition to the Professorship of Materia Medica and Therapeutics); Dr. Lewis A. Stimson, Professor of Surgical Pathology (instead of Pathological Anatomy); Dr. Stephen Smith, Professor of Clinical Surgery (instead of Orthopædic Surgery); Dr. Herman Knapp, Professor of Ophthalmology; Dr. F. R. S. Drake, Clinical Lecturer on Practice of Medicine; Dr. N. M. Shaffer, Clinical Lecturer on Orthopædic Surgery; Dr. Joseph E. Winters, Clinical Lecturer on Diseases of Children (in addition to being Demonstrator of Anatomy); Dr. William C. Jarvis, Clinical Lecturer on Laryngology; and Dr. Lawrence Johnson, Lecturer on Medical Botany.

THE presence of small-pox in Cape Town is arousing the inhabitants to a sense of the value of vaccination. Mr. Frederick Ensor, District Surgeon, Port Elizabeth, has issued a public appeal, calling attention to the danger of neglecting the means of coping with the epidemic afforded by the operation.

AMONG the naval medical officers present at the bombardment of Alexandria was Fleet-Surgeon Henry Nanton Murray Sedgwick, of H.M.S. *Inflexible*. This distinguished officer is a son of the late Hon. Samuel Sedgwick, M.A., M.D. He entered the Royal Navy as Assistant Surgeon in 1862, became Surgeon in 1869, in which rank he served with distinction throughout the Abyssinian campaign under Lord Napier of Magdala, and was several times mentioned in despatches; for his services he received the war medal and the promotion to Staff Surgeon. In 1879 he was further promoted to the rank of Fleet Surgeon, and in the autumn of last year was appointed to the *Inflexible*, before which time Dr. Sedgwick was Senior Medical Officer in charge of H.M. training ship *St. Vincent*, stationed at Southsea.

A PROPOSITION has been made to establish a Society of Medical Men practising in the Western District of London. Circulars have been issued pretty extensively to solicit attendance at a meeting to be held on Friday (to-day), at 5 P.M., in the Board-room of the West London Hospital, when the matter will be discussed.

IN consequence of the prevalence of scarlet fever at West Moseley, Dr. Price Jones advised the closing of the school of the locality. The managers have, however, it is stated, declined to comply with this advice, on the ground that the number of cases existing in the village is not sufficient to justify that course.

IN the loss sustained by Mr. James Mackie, surgeon to H.M. Consulate at Alexandria, by the destruction of his house in that city, is included an almost unique collection of calculi, the result of twenty-two years' surgical work in the Deaconesses' Hospital; also his library and all his surgical apparatus.

THE seat left vacant in the section of Medical Physics and Chemistry of the Académie de Médecine by the death of M. Briquet has been filled by the election of M. Gariel, who received fifty-seven of the votes of the sixty-eight Academicians present.

WE understand that an etching of the portrait of Mr. Luther Holden, by Mr. Millais, has been executed by Mr. Muller, of Devonshire-street, Portland-place, and that a copy has been presented to each of the subscribers.

THE Board of Trade have received through the Secretary of State for Foreign Affairs a copy of a notice issued by the Portuguese Government declaring the ports of the Province of Rio de Janeiro free from yellow fever since the 16th ultimo.

M. FAUVEL relates an instance in which he found a bullet in the larynx ten years after it had entered the head.

THE Bradshawe Lecture will be delivered this year by Dr. Long Fox on Friday, August 18th. The subject will be "The Influence of the Sympathetic System on Disease."

LEDWICH SCHOOL OF MEDICINE, DUBLIN.—The following prizes have been awarded at the termination of the summer session:—Botany and Zoology: Shirley Roberts (1st); Samuel Horneck (2nd). Materia Medica: S. Finlay (1st); J. J. Bolger, F. W. Sullivan (equal). Practical Chemistry: J. H. Griffin (1st); M. Leaby (2nd). Forensic Medicine: T. Williams (1st); W. Fryer, G. Wood (certificates). Midwifery: E. Wynne (1st); W. Fryer (2nd).

## Public Health and Poor Law.

### LOCAL GOVERNMENT DEPARTMENT.

#### REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Gloucestershire Combined District.*—The annual report on the sanitary condition of the district to which Dr. Bond acts as medical officer of health must be of interest, if for no other reason, because of the magnitude of the area dealt with. It includes five urban and eight rural districts, covering in all some 620 square miles, and having at the census of 1881 a population of 123,333. When it is found that in a district of this character there has been for eight years a decline in the prevalence of zymotic diseases, broken only by one single rebound, and that whereas in 1874 as many as 301 deaths were registered from such diseases, as opposed to 152 in 1881, there are certainly grounds for assuming that the sanitary supervision to which the district has been subjected during those years has exercised a very decided influence for good, and that the cost of the sanitary measures which have been adopted has by no means been thrown away. Indeed, we concur with Dr. Bond in the opinion that the result affords a very tangible proof that the expenditure of the ratepayers has borne solid fruit in protecting the health and adding to the comfort of the community, and that it has hence been a true measure of economy. The continued fevers of all diseases those which are most influenced by the adoption of an efficient sanitary administration, and we note that whereas in the four years 1874–77 there were 163 deaths from this form of fever, nearly all the cases being of the enteric type, only 106 occurred in the period 1878–81; and not only so, but an almost steady diminution in the annual number registered has gone on from 57 in 1875 to 17 in 1881. Much the same holds good as regards diarrhoea. The views which are expressed by Dr. Bond in many portions of his report as to the possible identity of diseases which he groups under the name of “scarlatinoid,” though by no means new, are still in advance of those held by many of his co-workers. He knows of no line of demarcation by which scarlatina, croup, and diphtheria can, even theoretically, be separated from one another, and he is of opinion that whilst scarlatina shades off into the diphtheritic group of affections on one side, it tends equally, on the other, to pass insensibly into measles. He also considers that cases are becoming increasingly frequent in which the so-called scarlatinoid poison affects a weakly patient with low powers of resistance, and that because of the patient's physical condition it concentrates itself on the throat and gives rise to conditions analogous to, if not identical with, those of diphtheria. The localisation of the symptoms as here described has often been observed in genuine scarlet fever, which has given rise by infection to other cases where the characteristic skin eruption predominated, and we fear that many possible sources of error must be removed before even a large group of such cases can be regarded as determining a question as to the identity or not of the poisons under consideration. So great are the difficulties, however, in fully understanding the relation which sore-throat bears to diphtheria or to scarlatina, that we feel convinced Dr. Bond is right in instructing teachers in elementary schools to regard all cases of sore-throat as infectious, and to refuse readmission to any scholars who may have suffered from scarlatina until all evidence of throat mischief has absolutely disappeared. A history of the spread of enteric fever in Westbury-on-Severn is worthy of notice. The disease was imported by a young man who was “boots” at one of the leading hotels in Gloucester; and Dr. Bond satisfied himself that it was due to faulty sanitary conditions which were easily detected. Up to that date they had, however, remained unremedied;

and this although one, if not two, of the previous holders of the young man's office had suffered and died from what was believed to have been enteric fever. Use is made of this history to refer to the sanitary condition of hotels generally, and to the condition of helplessness in which the public are placed in the matter. They certainly have a right to be as much protected when lodging in an hotel as when occupying a common lodging-house or houses let in lodgings. Provision is made by by-laws and otherwise as regards the two latter class of houses; but the hotels, which are, after all, only large lodging-houses, are free from all special sanitary control, and the public resorting to them have no guarantee as to their reasonable healthiness.

*Buxton.*—This urban district was remarkably free from fatal cases of any of the infectious fevers during 1881, and steady progress is being made in sanitary work. A curious case of typhoid fever is alleged as having occurred in a boy as the result of falling into an excavation containing long pent-up sewage. The data given do not suffice for the expression of a decided opinion as to the origin of the disease, but the period of incubation was apparently limited to one week. If this were so, the incubation stage was one of somewhat unusual brevity, and the question arises whether the history as related does not admit of the disease having been due to the inhalation of sewage emanations at a date preceding the fall in question.

*Hackney.*—From Dr. Tripe's report on the sanitary condition of the Hackney district, it appears that during the last ten years the increase in the population has amounted to 60,000, it having been nearly at the rate of 50 per cent. In July of last year it was estimated at 188,240, and amounted to 47 8 per acre, no allowance being made for 467 acres, including marshes and water which cannot be built on. On several occasions Dr. Tripe has referred to the injurious influence of the Homerton Small-pox Hospital upon that portion of his district lying within a certain area of that institution; and more extended observation entirely confirms the opinions he has previously expressed. On this occasion, however, Dr. Tripe says he is inclined to regard such injurious influence as practically inoperative provided a small-pox hospital is so situated with regard to site as to admit of an acre of land for every 25 patients under treatment, and a space of at least 150 feet between the wards and the walls surrounding the site; and also provided the number of patients massed together in one centre does not amount to more than 100. He also considers that the risk of the spread of infection to surrounding houses by aerial and other means increases with the increase of patients beyond the number stated. We assume that Dr. Tripe has had an opportunity of explaining his views on this subject before the Royal Commission on Infectious Hospitals, and we are inclined to look upon the remedial measures suggested by him as being in the direction in which action will have to be taken as regards the isolation of small-pox in London and other large towns. Dealing with the details of a local small-pox prevalence, Dr. Tripe brings forward statistics to show that the efficiency of primary vaccination tends to wear out at about the tenth year of life; and judging from the small-pox death-rates amongst the vaccinated, he considers that it is conclusively shown that the necessity for revaccination arises between the seventh and tenth years. Amongst many other interesting matters, Dr. Tripe explains why Hackney is so free from trades associated with the development of offensive effluvia. Persons proposing to establish manufactories which might be expected to evolve unpleasant and deleterious vapours are informed in advance that directly nuisance arises proceedings will be commenced against them, the result being that they transfer their business to other districts.

*Tottenham (Urban).*—In Dr. Watson's report upon the health of this suburban district during last year, he calls attention to the fact that its population, which was 22,869 in 1871, had more than doubled at the time of the last census, having become 46,441. The birth-rate among this population was equal to 41·5, whereas the death-rate did not exceed 16·8 per 1000. The death-rate did not vary materially from those which prevailed in the two preceding weeks, which were 16·5 and 17·6 per 1000 respectively. The deaths referred to the principal zymotic diseases were 131, or 17 per cent., of the total deaths, and were equal to a rate of 2·8 per 1000. This large proportion of zymotic diseases can scarcely

be deemed satisfactory; the fatality from these diseases was not due to the epidemic prevalence of any one disease, but included 34 from diarrhoea, 33 from whooping-cough, 22 from scarlet fever, 20 from diphtheria, 10 from measles, 10 from "fever," and 2 from small-pox. The fatal cases of diphtheria exceeded the number returned in any of the ten preceding years. Dr. Watson reports that Tottenham has now completely outgrown its sewerage system, which requires the urgent attention of the sanitary authority, and expresses the opinion that the adoption and completion of a thoroughly effectual drainage scheme would be followed by a marked diminution in the general and zymotic death-rates. It is noted that the causes of no fewer than 36 or nearly 5 per cent. of the deaths registered during the year were uncertified. The value of this report would be enhanced by a summary table showing a few of the more important features of the mortality statistics of Tottenham in a series of recent years.

### VITAL STATISTICS.

#### HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns, 5574 births and 3090 deaths were registered during the week ending the 22nd inst. The annual death-rate in these towns, which in the two preceding weeks had been equal to 18·4 and 19·2 per 1000, was last week 19·0. The lowest rates in these towns last week were 8·1 in Derby, 14·6 in Bradford, 15·1 in Bristol, and 16·1 in Birmingham. The rates in the other towns ranged upwards to 24·8 in Leicester, 25·0 in Sunderland, 26·4 in Bolton, and 30·4 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns were 569, showing a further increase of 33 upon recent weekly numbers; 281 resulted from diarrhoea, 102 from whooping-cough, 66 from measles, 57 from scarlet fever, 34 from "fever" (principally enteric), 20 from diphtheria, and 9 from small-pox. The lowest death-rates from these diseases occurred in Brighton and Plymouth, and the highest in Leicester and Preston. Whooping-cough caused the highest death-rates in Newcastle-upon-Tyne and Nottingham; scarlet fever in Sunderland and Hull; measles in Derby and Huddersfield; and "fever" in Portsmouth and Sunderland. The deaths referred to diarrhoea in the twenty-eight towns showed a further increase last week upon recent weekly numbers, but were considerably below the average for the season; the fatality of this disease was greatest in Preston and Leicester. The 20 deaths from diphtheria in the twenty-eight towns included 13 in London and 2 in Portsmouth. Four fatal cases of small-pox were recorded in London, 3 in Leeds, and one each in Manchester and Newcastle-upon-Tyne. The number of small-pox patients in the metropolitan asylum hospitals, which had declined in the thirteen preceding weeks from 350 to 204, further fell to 193 on Saturday last; 20 new cases of small-pox were admitted to these hospitals during last week, against 30 and 23 in the two previous weeks. The deaths referred to diseases of the respiratory organs in London, which had been 173 and 199 in the two preceding weeks, declined to 157 last week, and were 27 below the corrected average number in the corresponding week of the last ten years. The causes of 71, or 2·3 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Portsmouth, Leicester, Bolton, and Huddersfield; whereas the proportions of uncertified deaths were largest in Halifax, Wolverhampton, Liverpool, Oldham, and Sunderland.

#### HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which had been equal to 20·5 and 21·3 per 1000 in the two preceding weeks, further rose to 21·7 in the week ending the 22nd inst., which exceeded by 2·7 the mean rate last week in the twenty-eight large English towns. The deaths referred to the principal zymotic diseases in these Scotch towns were 113 last week, showing a further slight increase upon recent weekly numbers; they included 60 from diarrhoea, 19 from measles, 16 from whooping-cough, 8 from scarlet fever, 2 from diphtheria, and one from small-pox. The death-rate from these principal zymotic diseases averaged 4·9 per 1000 in the eight towns, and was 1·4 above

the mean rate from the same diseases in large English towns. The 60 fatal cases of diarrhoea showed a further increase upon recent weekly numbers, and exceeded by no fewer than 38 the number returned in the corresponding week of last year; 37 occurred in Glasgow, 6 in Paisley, and 5 both in Edinburgh and Leith. The annual death-rate from diarrhoea in the Scotch towns was last week nearly twice as high as that which prevailed in the English towns. The 19 fatal cases of measles were within one of the number in the previous week, and included 9 in Dundee, 4 in Leith, and 3 in Aberdeen; the 9 fatal cases in Dundee showed a decline of five from the number in the previous week. The 16 deaths from whooping-cough exceeded those of the previous week by 2, and included 7 in Glasgow, 4 in Edinburgh, and 3 in Aberdeen. Three of the 8 deaths from scarlet fever occurred in Glasgow, and two both in Paisley and Leith. The deaths referred to "fever" corresponded with the number in the previous week, and included 2 both in Glasgow and Leith. Both fatal cases of diphtheria were returned in Edinburgh; Dr. Littlejohn, the medical officer of health for the city, only reports, however, one death from this disease. The death from small-pox was recorded in Aberdeen, and was of a fisherman on board a French lugger. The deaths referred to acute diseases of the lungs in the eight towns, which had been 92 and 95 in the two previous weeks, declined to 80 last week, and exceeded by one the number attributed to these diseases in the corresponding week of last year.

#### HEALTH OF DUBLIN.

The rate of mortality in Dublin, which in the four preceding weeks had declined from 23·2 to 16·8 per 1000, rose again to 21·9 in the week ending the 22nd. During the first three weeks of the current quarter the death-rate in the city averaged 19·7 per 1000, against 17·7 in London and 19·1 in Edinburgh. The 146 deaths in Dublin last week showed an increase of 34 upon the exceptionally low number in the previous week, and included 7 which were referred to diarrhoea, one to scarlet fever, and not one either to small-pox, measles, diphtheria, whooping-cough, or "fever." Thus only 8 deaths resulted from these principal zymotic diseases, against 14 and 9 in the two previous weeks; these 8 deaths were equal to an annual rate of but 1·2 per 1000, against 3·3 in London and 2·9 in Edinburgh. The deaths attributed to diarrhoea, which had been 5 in each of the two preceding weeks, rose to 7 last week. The fatal case of scarlet fever raised the number recorded since the beginning of April to 8. Last week was the first since the beginning of the year in which no death from "fever" has been recorded within the city. The deaths of infants showed a further increase upon recent weekly numbers, while those of elderly persons were less numerous. The causes of 19 or more than 13 per cent. of deaths in the week were uncertified.

#### CENSUS REPORTS: COUNTY MONAGHAN.

The population last year was returned as 102,748, a number ten per cent. less than in 1871, when the total was 114,969. The number of persons receiving Poor-law relief in 1871 was 608, or 1 in every 189 of the population; in 1881 the number was 872, or 1 in every 118, of which 736 were indoor and 136 outdoor paupers. As regards the condition of elementary education, 51·1 per cent. could read and write, 18·1 read only, and 30·8 were wholly illiterate.

### THE SERVICES.

**ARMY MEDICAL DEPARTMENT.**—Surgeon-Major Benjamin Lane has been granted retired pay, with the honorary rank of Brigade Surgeon.

The Queen has approved of the retirement of Surgeon-Major George William Jameson, of the Bengal Army.

Surgeon-Major John Law, M.D., of the Madras Army, to be Brigade Surgeon.

**RIFLE VOLUNTEERS.**—Surgeon and Honorary Surgeon-Major Thomas Gray, M.D., resigns his commission; as so is permitted to retain his rank, and to continue to wear the uniform of the Corps on his retirement.—14th Middlesex (Inns of Court): John H. Morgan, M.A., F.R.C.S., has been promoted Surgeon, vice Couson, retired.—5th West

Riding of Yorkshire: Francis Henry Wood, Gent., to be Acting Surgeon.

ADMIRALTY.—The following appointments have been made: Fleet Surgeon Ingham Hanbury, to the medical charge of the Royal Marine Battalion in Ireland; Staff Surgeon Charles G. Wodsworth, to the *Thalia*; Staff Surgeons James H. Martin and Thomas Conry, to the *President*; Surgeon W. G. C. Smith, M.B., to the *Triton*, for temporary service; Surgeon William F. Spencer, to the *Thalia*; Surgeon H. M. Ellis, for service with the Marines in the *Dacca*; Surgeon Alfred H. Kelly, to the Royal Marine Artillery Division, vice Ellis; Surgeon Edmund D. Maddick, to the *Duke of Wellington*; Surgeon Arthur W. Russell, to the *Victor Emanuel*; Surgeon John A. MacMunn to Hong Kong Hospital (in charge).

### GLASGOW ROYAL INFIRMARY SCHOOL OF MEDICINE.

THE new building which has been in course of erection for the School of Medicine in connexion with the Royal Infirmary is now being rapidly completed, and will be ready for occupation in all departments at the commencement of the coming winter session. The anatomical section of the School is already occupied. The dissecting-room measures 70 ft. in length, 25 ft. in breadth, and is over 25 ft. in height. It has been constructed with particular regard to lighting and ventilation, and is fitted up and supplied with everything requisite for the convenience and comfort of the students. The building also contains lecture theatres and anatomical museums. The osteological room is fitted up as a private reading-room, and contains an ample supply of specimens. In the large dissecting-room are placed some fine frozen specimens of dissections illustrating most of the more important regions of the body; these are arranged in uniform circular glass jars, conveniently placed so as to allow them to be referred to by the students during the progress of their practical work. The south side of the building is occupied by the large, well lighted and ventilated chemical and physiological theatres and class-rooms for general instruction and experimentation, in which are all the modern instruments requisite for these special branches of study. The committee have also apportioned a large room for a general medical library, which will be used as a place of meeting of the Glasgow Royal Infirmary Medical Society.

"Audi alteram partem."

### DEATHS UNDER CHLOROFORM.

To the Editor of THE LANCET.

SIR,—Twenty years spent in the study of that protean disorder indigestion have taught me much in reference to the depth of sympathy that exists between heart and digestive organs.

One of my patients of former years, a muscular man of first-class pedestrian ability, invariably became the victim of faintness if he partook of veal-pie. Another exhibited the symptoms of angina pectoris if he took into his stomach food either excessive in quantity or unsuitable in character. A third, still frequently under treatment, becomes both faint and asthmatic after the imbibition of tea. Nevertheless, the individual referred to can pace the floor persistently whilst in the enjoyment of the—to him intense—luxury of a prolonged Turkish bath, heated to a high temperature. A lady patient suffers from faintness, followed by an attack of urticaria, after the eating of roast mutton, a dish of which she is particularly fond. Is this sympathy sufficiently reckoned, or guarded against, in the preparation of a patient for the inhalation of an anæsthetic? I fear not, Sir. As a fact, should not his diet be, when such a course is open to the surgeon, carefully supervised for two or three days previously to the administration of the drug? Every death that takes place during the administration of an anæsthetic not only causes honest

men and good surgeons to be lightly spoken of, but also, and still more important, brings discredit upon surgery.

I shall be very glad if some of my professional brethren, the bent of whose studies has been parallel with my own, will give us the benefit of their opinion upon this all-important subject.

And now, Sir, if you please, permit me to indite a line in reference to the restoration of those whose lives hang upon a single hair in consequence of the inspiration of chloroform. A relative of my own suffered, when at about the age of twenty, from an attack of rheumatic fever coupled with valvular disease of the left side of the heart. At the approach of the critical seven-times-seven, acute rheumatism, this time associated with disease in the right side of the heart, again attacked him. Anasarca speedily set in, and the case assumed hopeless features. One morning about six o'clock, when I had been in close attendance upon him for several hours, sudden failure of the heart's action seized him. Fortunately, a supply of very hot water lay close at hand; I dipped a folded towel into the fluid, and laid it, after the least possible delay, upon the patient's chest. In a short time he revived. I quitted his side for ever that morning. His attendants had, however, learned their lesson. They repeated the application on the supervention of each subsequent faintness, the total result being that his life was prolonged for many days—until, in fact, an increase of anasarca rendered a continuance of existence impossible.

Why should not a fair trial be accorded to the hot-water plan of treatment in cases of anæsthesia threatening the extinction of the vital flame?

Yours faithfully,  
Canterbury, July 26th, 1882. JOHN BEADNELL GILL, M.D.

### "STAMPING OUT SMALL-POX."

To the Editor of THE LANCET.

SIR,—Under the above heading I notice in last week's LANCET a short account of the measures which are being adopted by the authorities at Leicester with a view of stamping out small-pox in that town, and as these measures appear to be somewhat similar to those adopted by the Government of New South Wales during the recent outbreak of small-pox in Sydney, where, as Special Government Medical Officer, I had very good opportunities of judging of their intrinsic value, I venture to make a few remarks upon the subject.

Vaccination not being compulsory in New South Wales, there existed a very large number of unvaccinated persons in Sydney, adults and children, small-pox being considered a *rara avis* very unlikely to visit that distant colony. However, as the unexpected generally happens, small-pox made its appearance in Sydney in June of last year, and was received with a feeling amounting to little less than panic, the commerce of the port being considerably interfered with, and the Government put to enormous expense. There was, of course, a great demand for immediate protection by vaccination, which could only be gradually and partially complied with. The Government took extraordinary measures under the Colonial Quarantine Act, and upon a suspected case of small-pox being reported to the authorities, the house was at once visited by a member of the Government medical staff, and if, on examination of the individual, the suspicion proved well founded, the house and its inmate were immediately placed in a state of strict quarantine, and no unauthorised person allowed to leave it, special police arrangements having been made to enable this to be effected. If the affected person was willing and fit to be removed to hospital that was done, and the other inmates, having been carefully vaccinated, were, if willing and there was accommodation, removed to the sanitary camp, an enclosed encampment erected several miles out of town as a quarantine station for apparently healthy inmates of infected houses. The house was then thoroughly disinfected and cleansed by a special disinfecting corps, and all infected clothing, &c., burnt. On the other hand, in cases where the persons attacked were either unwilling or unfit to leave their houses, they were attended by the special Government medical staff, and were supplied with necessary medicine, food, bedding, &c., and nurses if required. The regular medical attendants would, on application, have received authority to enter and leave quarantine houses in

order to treat their patients, but there was such a small-pox scare that it would have been ruinous for a medical man in ordinary practice to be seen entering or leaving such houses; the treatment, therefore, with one homoeopathic exception, devolved entirely upon the Government medical staff specially appointed. All the unaffected inmates were vaccinated, if willing, and either removed to the sanitary camp or quarantined in the infected houses, kept under observation, and supplied with food, clothing, disinfectants, &c., and on release compensated by the Government for their loss of time, &c. The compensation was, however, necessarily very inadequate for the loss of employment in many instances, and the ruin of business in the case of shopkeepers, whose stock-in-trade was spoilt and customers dispersed, many of the houses having to be kept in a state of quarantine for six or eight weeks or more. This state of things naturally led to a great dread of quarantine and to a considerable amount of concealment of the disease, there being no Act to compel the notification of infectious diseases, and in several instances hot-beds of infection were thus created, unknown to the authorities or even to the neighbours, with very troublesome and serious results, frustrating the attempts to arrest the disease and protracting the outbreak.

The epidemic never really assumed very extensive proportions, which fact must, I think, be greatly ascribed to the quarantine regulations, especially when the great number of unvaccinated people in the city, and especially in the infected districts, is taken into consideration. These measures no doubt confined the disease, in most cases, to a few houses, whereas otherwise it would have spread to many, while the prompt and very general vaccination and revaccination of the surrounding neighbours effectually limited or arrested its career by starving it out. The outbreak was at an end in eight months, and may, I think, under the circumstance, be fairly said to have been "stamped out." There can be no doubt that this would have been accomplished much sooner, and with much less expense and trouble had vaccination been compulsory, and had an Act for the compulsory notification of infectious diseases been in force. I quite agree with your remarks, that "the efficient vaccination and revaccination of the public generally are far more efficacious protections against small-pox than the mere isolation of the few who are known to have come into contact with infection."

Isolation by the quarantine system is doubtless a valuable sanitary measure in outbreaks of small-pox occurring in towns like Leicester and Sydney, where vaccination has been greatly neglected; but it is very harsh and severe in application, impracticable in many cases, and most expensive. It can at best only rank as an assistant to that great prophylactic vaccination in the stamping out of small-pox, and it is trusting to a broken reed to rely upon it as at all a substitute for efficient vaccination of communities.

I am, Sir, yours faithfully.

J. HIGHAM HILL, M.D., F.R.C.S.E.

Bedford-place, W.C., July 18th, 1882.

#### A CASE OF "TRUE EASTERN LEPROSY" IN ITS EARLY STAGES TREATED BY CHAULMOOGRA OIL.

To the Editor of THE LANCET.

SIR,—An interesting case of early symptoms of true Eastern leprosy, showing lesions of the trophic nerves and the skin, and illustrative of trophic changes, came under my notice through the kindness of Dr. Corbett of Kingston-on-Thames, who called me to see it, and I am therefore enabled to send you the notes of the case.

The patient, who has been in England now for four years, had traces of the disease, he states, about sixteen or seventeen years ago, and about twelve months since got very much worse—a formation of tubercles and ulcers taking place, which would not heal under all ordinary treatment. For the previous eight years, the patient stated, he had lived a very hard life in Africa (Southern) amongst the diamond-fields, digging and washing diamonds; and whilst there he was exposed to great heat in the day, and damp, cold, and miasma at night; he could get no fresh vegetables, and, indeed, hardly any food sometimes, and that of an indifferent character. Previous to his living in the diamond-fields, he was exposed to much privation on the sea. Sometimes he

rara, and had at times very bad food. He had also resided twenty years ago in Rio Janeiro; and—in my opinion a most important element in this history—he had a very bad attack of ague twelve years ago, relapses of which he has had several times since, some being worse than others. The patient is a short, thick-set, short-necked man, with sallow complexion and curvature of the spine in the upper part of the column. He is about forty-five years of age. He now has many small hard tubercles in different parts of his body, more especially on the hands and feet, on the dorsal surfaces, on the shoulders, legs, and thighs, face and ears, with also the remains of an eruption of maculae, brownish in tint. These tubercles are hard and nodular to the touch, and nearly all suppurating. The ulnar and peroneal nerves are much thickened and tender to the touch. There is slight wasting of the muscles of the thumb and interossei; the sight is getting weak, and there is slight opacity of the left cornea, and he complains of great loss of muscular power; he has lost sexual power, and has a feeling of numbness and of pricking sensation in the hands and feet, along with fits of depression. All these symptoms go to show the true character of the disease. He has little or no loss of sensation in his body, in any of the patches or otherwise, like the case I reported to you in 1880.

After many applications both of specific and other kinds had been applied to this case, with little or no benefit to the patient, Dr. Corbett consulted me as to the nature of the case and its treatment. We came to the conclusion that it was a case of true Eastern leprosy in its early stages, and we resolved to give the patient chaulmoogra oil, both internally and externally. He was ordered three capsules of oil three times a day, and the crude oil to be rubbed into the parts well whenever affected twice a day. From the time this treatment was adopted the patient improved, and on July 4th Dr. Corbett writes to say: "I do not think I can add much to the history of the case or its description, except to supply the omission, that the tubercles, after suppurating, left deep ulcers with sharply defined edges and smooth sores, which no treatment, tonic or alterative, seemed to heal until the chaulmoogra oil was taken, when in a few weeks reparative action was set up, and they all quite healed. Fresh tubercles, not many in number, and entirely confined to the dorsum of the hands and feet, including the fingers and toes, still form and suppurate, but not one has resulted in ulceration. Since the oil has been taken, in fact, a good many of the tubercles do not suppurate, become abortive, and die away."

Now this case, as well as the last I reported to you, were much benefited by the administration of chaulmoogra oil; in fact, the case I reported in October, 1880, is as nearly well as can be, and the man is able to resume all his duties. I saw this patient last week at Kingston, and he assured me he was much better, and he had very few tubercles left. In my opinion, leprosy can be relieved, if not cured; and this opinion is shared now by other members of the profession. Mr. Hutchinson states he has seen cases that have quite recovered.

Your obedient servant,

Sackville-street, July 12th, 1882.

JAMES STARTIN.

#### CASE OF CEREBRAL COMPRESSION TREATED BY BLEEDING AND CALOMEL.

To the Editor of THE LANCET.

SIR,—In reading lately some very old numbers of a medical publication I was struck with the indiscriminate way in which the above remedies were used by the practitioners of the day. There are many hundreds of cases reported in the volumes I possess, and in very nearly every case bleeding and calomel appear to have been the sheet anchors of treatment. A very large percentage of the patients died, and reading the report, having our minds enlightened by the physiological knowledge of the present day, points very strongly to the conclusion that the remedy was worse than the disease, and moreover, the immediate cause of death. There are, however, many cases recorded which strikingly show the value of the old antiphlogistic treatment when used rationally in appropriate cases, and I determined to try the effect at the earliest opportunity, which I did in the following case.

I was called to see a child, two years and a half old, at six A.M. on April 8th. The child was perfectly well on the

previous day. The mother went out early in the evening, leaving the child in good health, but on her return it had been sick and seemed silly. She gave it a hot bath and put it to bed; it was restless all night, but slept. At half-past four A.M. the mother found it in a fit; she gave it a bath and tried various homely remedies until six o'clock, when she sent for me. I found the little patient comatose, stretched full length on its mother's lap; pupils fully dilated, and insensible to light; slow stertorous breathing; urine retained; faeces passed involuntarily; laboured slow pulse, and left hemiplegia, which I treated by tickling the palms and soles; the right limbs were withdrawn, the left remained stationary. Here was evidently a case of compression of the brain, which had come on so suddenly that it could be nothing but blood or depressed fracture of the skull, yet no bruise or depression could be seen or felt on the head, and the possibility of injury was vigorously denied by its parents. I immediately gave two grains of calomel, ordered ice to the head, sinapisms to the calves, and drew off its urine. I saw the child again at eight o'clock; pupils not so dilated, nor breathing so stertorous. I again visited the child at half-past ten, and found it had relapsed into its former condition. On this occasion I interviewed a boy who had been in bed on my previous visits, and from him I learned that while the mother was out the preceding evening he had seen the child fall with the right side of its head against a brick wall in the garden. I took four ounces of blood from the left temple, and ordered a quarter of a grain of calomel every quarter of an hour. In two hours the patient was staring about bewildered, but not comatose; pupils still dilated, but not nearly to so great an extent; breathing easier. From this time the child has manifested a daily improvement; he is now in his usual good spirits, but studiously avoids any pressure to the right side of his head. The hemiplegia is rapidly disappearing under the influence of two-grain doses of iodide of potassium every four hours.

I should strongly oppose a revival of the old system of bleeding and mercurialisation as it was formerly used, but I think such cases as this tend to show that such treatment is valuable in certain cases and does not deserve the sweeping condemnation it gets. Had I followed the orthodox treatment, the probability is that this patient would have gone to the great majority of those on whom the operation of trephining has been performed, whereas he is now alive and on a fair road to health. It would be instructive if other members of the profession who share the opinions I have expressed would publish their experiences.

I am, Sir, yours truly,

July, 1882. HERBERT H. MEYERS, M.R.C.S., &c.

## "DOCTOR OR DRUGGIST?"

*To the Editor of THE LANCET.*

SIR,—As to medical practitioners dispensing and supplying their own medicines, the whole of my observation and experience goes to prove that it is most desirable that the profession generally should hold fast to this privilege, and for the following good reasons: We maintain a firmer hold over our patients, retain their confidence longer and better, prevent them from drugging and treating themselves and those under their charge with unnecessary (and sometimes injurious) medicines. We frequently have more opportunities of seeing and treating diseases in their earlier stages, and thereby saving the lives of our patients. We can save expense to our patients, and indirectly increase our own incomes, a desideratum not to be lost sight of during these times of bad trade, keen competition, lowering of fees, and struggling to keep up respectable appearances in society. I maintain that every practitioner should be in a position to supply his own patients with all medical and surgical remedies whenever they prefer such, and that these remedies can very conveniently, and with dignity and pleasure, be included in the general professional fees for visit, advice, operation, &c. When a practitioner is awkward in dispensing, or has not time to do so properly, he can keep an assistant or pupil to dispense for him, or if he cannot do this he will probably have little difficulty in arranging with some one or more of his professional neighbours to employ a qualified dispenser, either to attend at their different residences at certain hours or to reside or attend at some central place set apart as a dispensary or surgery for such purpose. This latter mode is becoming

general in many large towns (Leicester for example), and is found to work satisfactorily. Or if neither of the two foregoing methods can be adopted, these practitioners can still arrange with some local and honourable druggist to dispense privately for them, and to deliver the medicines either at their own residences or at their patients' houses. One of my practices was almost exclusively prescribing, having become so on account of my predecessor having held appointments which prohibited dispensing; and in two of my other practices my patients had their own choice as to whether prescriptions or medicines were supplied, and the general result proves the following further conclusions:—A very great majority (more than ninety per cent.) prefer to have medicines direct from the medical attendants, many positively refusing to go to the chemist's with their prescriptions, on account of the possibility of his suspecting or knowing that they are suffering from such and such diseases—to say nothing about the extra time, trouble, and expense they are generally put to by doing so. I have frequently detected errors and omissions on the part of dispensing chemists and druggists who have been entrusted with dispensing from my prescriptions (which are generally written fully, explicitly, and, in the case of new remedies, always after making myself practically acquainted with the best and most convenient mode of condensing and administering), besides, not infrequently exorbitant charges, considering the cost price of the remedies prescribed. Doing one's own dispensing nowadays does not involve the time and trouble it did twenty years ago, since every practitioner, by exercising a little forethought, can have most of his remedies prepared by his wholesale or manufacturing druggist—e.g., coated pills, concentrated infusions and decoctions, saturated solutions of salts and alkaloids, spread plasters, prepared ointments, and standard or private formulæ similarly prepared to hand; also cut wrapping papers, washed and corked bottles, and printed labels and wafers as desired. Further, if need be, practitioners can do almost the whole of their own dispensing at their patients' houses simply by carrying with them, either in their pockets or carriages, the chief medicines they are in the habit of employing; and in this latter mode Dr. Kirby has done much to popularise portable remedies in the form of coated pills and compact cases; while Messrs. Squire have also done something by preparing discs and laminae of the more important alkaloids for hypodermic use; and I should also add Dr. Boerhaave in introducing his dosimetric system of administering active remedies.

I trust I have now stated enough, although I could say even much more if time and your valuable space permitted, to prove the advisability of our retaining in any new medical Act due provision for exercising the art of compounding and dispensing (and charging for) medicines supplied to our own patients; of retaining the Worshipful Society of Apothecaries as an examining and licensing body, in common with the other bodies, or, at least, of keeping the legal power and function now possessed by that Society; and of practitioners generally being in a position to dispense and supply their own patients with medicines; and last, though not least, of speedily ridding our minds of the just now fashionable delusion (among some members of the profession) that in dispensing and supplying our patients with medicines we are in some way degrading ourselves in the estimation of the public.

I am, Sir, yours truly,

Clifton, July, 1882. JOHN BROOM, M.D., &c.

## PERFORATING DUODENAL ULCER.

*To the Editor of THE LANCET.*

SIR,—A case of duodenal ulcer came under my notice recently, the details of which appear to me to be worthy of record.

John P—, aged thirty-four, a coachman, and a well-built, active, muscular man, apparently in robust health, consulted me in November, 1881, having been suddenly seized with agonising pain in the right hypochondriac region, extending downwards and to the back. The pulse was slow, of good strength; the skin cool, and in twelve hours he was free from pain. Morphia was injected subcutaneously. During the succeeding six months he had occasional attacks of abdominal pain and sickness, not, however, of such severity as to induce him to seek medical aid or to interfere

with his work. While in the act of stretching himself to hang a picture on the evening of April 23rd, 1881, about an hour after a meal of tea and bread-and-butter, he was again suddenly seized with the same pain as before, and when seen was in a chair, moaning, with the knees drawn up, pale, with a cool skin and a slow but not weak pulse. Bowels had acted during the day. Morphia was again injected with but little relief, and by the following evening he was in a state of profound collapse, and died in twenty-four hours after the seizure.

The abdomen was examined twenty-four hours after death. Rigor mortis complete, with great lividity of surface and rapid decomposition. On opening the abdomen, fetid gas and about two quarts of turbid brown fluid, with yellow floating shreds, escaped, and on raising the transverse colon a round perforation, half an inch in diameter, was seen in the duodenum, which was perfectly free from adhesions. The omentum had limited to some extent the spread of the peritonitis, but there was much soft yellow lymph on the liver and the adjacent bowel. On removing the duodenum, the opening was seen to have a thick rounded margin, firm to the touch, surrounded by folds of mucous membrane radiating from it.

Three years ago George S—, aged thirty-six years, while jumping on the hind step of a high gig, was seized with extreme pain in the abdomen and faintness. When seen by me he presented the phenomenon of collapse in the most intense degree, and for about six hours showed no sign of rallying. Gradually the pulse became perceptible, and warmth returned, but the abdominal pain was extreme, and for three days he lay in a dangerous state. In eight days he had recovered sufficiently to be removed to his home, a distance of some miles, and when heard of six months ago was alive and well. Previously for some months he had occasional attacks of abdominal pain, which he attributed to "cramp."

I am, Sir, your obedient servant,

W. HENDERSON, M.B. GLASG.

Stanhope-terrace, N.W., July, 1882.

## SCOTTISH NOTES.

(From our Correspondent.)

ARRANGEMENTS are now complete in several towns in Scotland under which the delivery of popular science lectures during next winter, by well-known scientists, is assured. Health subjects are popularised by Dr. A. Wilson, of Edinburgh, and Professor Stirling, of Aberdeen, both of whom have shown quite exceptional power in bringing scientific knowledge within the grasp of the ordinary intelligence. These are the lecturers sent under the Combe Trust, and the Gilchrist Trustees purpose a similar course to that so successfully carried out last year. The eminence of the lecturers, their popular subjects, and the nominal charges were the means of attracting audiences numbering in many cases thousands, and this year several new towns have urgently asked to be placed on the circuit. In many cases the local medical men will again deliver courses of health lectures. These are in some instances reproduced in book form, and in the case of Edinburgh, at least, over 20,000 copies have been sold.

The local examinations conducted by the various Scotch universities have now been completed for the year. The popularity of these increases rapidly, and this year about 2400 pupils have come forward with very gratifying success. The medical interest in these arises chiefly from the fact that they offer an organisation of a satisfactory kind for relieving the universities and corporations from the task of conducting the preliminary examinations of medical students. At the recent meeting of the Medical Council some difficulty was said to exist on the part of the Scotch corporations, who had no body to which to depute this power, but facilities are here offered which would be convenient to the student and satisfactory to the Council.

The new hospital at Ayr approaches completion. It has an imposing frontage of 400 ft., and its central part is three storeys high. Accommodation is provided for forty-four beds in the main section, and in a detached portion twenty beds will be provided for fever patients. The rooms for the various officials are conveniently placed, and all modern hospital requirements have been provided. The cost will

be about £8000, and most of this money is already subscribed.

St. Andrews is making large additions to its meagre hospital accommodation. A temporary hospital will be erected at a cost of £500. This, as well as the more substantial structure proposed, is for the reception of ordinary cases of disease; while the Gibson Hospital, now being erected at a cost of £4000, is intended for the maintenance of such of the aged, sick, and infirm poor of the city and parish as the funds may prove sufficient to support. The building will probably be ready for occupation early next summer. Provision is made for eighteen persons, each having a separate room.

It is satisfactory to note that the body of the late Earl of Crawford was in a complete state of preservation when found. The thieves had placed the body in a gravelly soil by the side of a brook, had wrapped it in a large blanket, and buried it about two feet deep. The features were so well preserved by the embalming process that no difficulty was felt in recognising the late nobleman.

## PARIS.

(From our Paris Correspondent.)

AT a clinical lecture at the Hôpital de la Charité, Professor Hardy observed that we are perhaps not altogether justified in giving up entirely the practice of bleeding. He said that this valuable remedy was rather abused in former years, but that the modern school have gone to the other extreme in bleeding very little, or not at all. In fact, so little is it practised nowadays, that it is by no means a rare thing to meet a medical man of twenty or thirty years' standing who had never used the lancet; and the students who now leave the school are scarcely ever taught what phlebotomy is, or what its uses are. To demonstrate the utility of bleeding from the arm, Professor Hardy presented a female patient, aged seventy-six, who was admitted into the hospital with great dyspnoea, depending on marked cardiac troubles. On examining the heart, Professor Hardy discovered that the organ was greatly distended, and a bruit de soufflé was heard at the apex, which pointed to mitral insufficiency. The tricuspid valve was affected in the same way, which was indicated by the jugular venous pulse. Professor Hardy diagnosed an aystolic condition of the heart, and bled the patient to 200 grammes, which afforded instantaneous relief to the most urgent symptoms.

M. Bouley submitted to the Academy of Sciences last week a paper, in the name of M. Carey, explaining how, by the aid of a new frigorific apparatus, he succeeded in destroying trichinæ in American salted pork. The apparatus produced 300 kilogrammes of ice in one hour. During nine days he preserved at freezing point 60,000 kilogrammes of ham, at an expense of only about 500 francs. But M. Colin, another veterinary surgeon of note, is rather sceptical about the efficiency of cold to freezing point in completely destroying the parasites, as, according to his experience, nothing short of boiling would annihilate them.

For a long time it was supposed that the habitat of trichinæ was confined to the muscular system of the pig, and that the other parts of the body of this animal enjoyed absolute immunity from them. M. Chatin has proved that the parasite exists equally in the adipose tissues, which he noticed particularly in bacon or salted pork; and which, he added, would necessitate the close examination of suspected meats in their fatty as well as their muscular parts. The same hygienist also found, with the aid of the microscope, a quantity of trichinæ at different degrees of development in the coats of the intestines. This discovery necessarily caused some alarm, as the bowels of the pig are imported to this country, and are employed for enveloping sausages prepared with indigenous meat.

M. Laborde, Chef du Laboratoire at the School of Medicine, desirous of disabusing the public mind of the imaginary atrocities of vivisection, got up a meeting with a view of performing publicly some experiments on live animals, for which purpose he had some frogs, rabbits, and dogs prepared for the occasion. But the moment he began his operations on a frog, a lady from the audience rushed up towards the table and protested vehemently against the performance of such experiments in public. The greater portion of the audience soon joined the lady in her protes-

tations, and the meeting broke up in the midst of the most uproarious confusion.

Dr. Coudereau, a young and promising physician, died at his residence in Paris on Wednesday, the 19th inst., from an attack of peritonitis, resulting from perforation of the bowels. The melancholy event occurred three days after an accident which happened to him. After hailing a cab in the street, and while in the act of running up to it, he was knocked down by another cab passing at the time. I have not been able to ascertain whether the perforation of the bowels was caused by the accident, or whether it was spontaneous. Dr. Coudereau was a man of great mental energy and public spirit. He occupied himself a great deal about hygienic matters, and was Vice-President of the Society of Inspectors of Insalubrious Lodgings in Paris. He was one of the founders of the Société d'Autopsie Mutuelle, instituted about five or six years ago, according to the statutes of which each member was bound to bequeath by will his skull and its contents to the laboratory of the Anthropological Society of Paris, with the view of prosecuting scientific researches. Owing to the great mortality among infants brought up by wet nurses, Dr. Coudereau conceived the idea of remedying this crying evil by founding a nursery in the environs of the town where infants were to be brought up by the bottle, under, of course, the strictest surveillance. The scheme was patronised by the Municipal Council, but when submitted to the Academy of Medicine for its opinion, it was rejected as being immoral. This opinion was expressed by Professor Depaul, but M. Jules Guérin, a sworn adversary of M. Depaul, retorted by saying that the present system so much in vogue of employing wet nurses is much more immoral.

A great treat was given to the inmates of the Salpêtrière on July 14th to celebrate the national fête. The festive board was presided over by an old woman named Cornaveau, who had just completed her 100th year. She has been thirty-one years in the institution.

Paris, July 26th, 1882.

## NEW YORK.

(From a Correspondent.)

THE scene enacted at the execution of the assassin Guiteau was such as was anticipated by those who had carefully studied his case from a medical point of view. With the rope around his neck he read a chapter from the Bible, and delivered his parting prayer of indecent blasphemy loaded with irrelevant sentiments with all the gusto of his former self. Finally, reciting a hymn composed by himself after the model of the nigger camp meeting songs, stating that he was about to go to meet the Lordie, with perfect composure, and a courage worthy of a better cause, he gave the signal for the drop by shouting, "Ready! glory! go!" Invitation by telegram was sent to several eminent alienists, which in most cases arrived too late to be acceptable, while in one case the telegram arrived on the day the examination was made. An unseemly squabble occurred over the body, but an autopsy was eventually made. Your exchanges will give the details, and I now enclose a copy of the report. In conversation with a leading alienist of New York city respecting the results of the examination of Guiteau's brain, he said that he regretted that so many omissions were made in the post-mortem examination. The expert witness who testified that Guiteau was insane had referred to several somatic anomalies, which, in his opinion, and taken in conjunction with Guiteau's hereditary history, were of strong collateral importance; the chief of these was asymmetry of the skull and face, probably indicative of a defect in cerebral development. Such defects are sometimes found in the group of lunatics to which Guiteau, in my opinion, belonged, and manifest themselves in deformity or asymmetry of the skull and brain, as well as in atyp of the gyri. Muhr, Stark, Jensen, and Schnele have described such cases. Under these circumstances the separate brain hemispheres should have been weighed in order to establish the difference in gravity. Judging by the difference in the dimensions of the two halves of the skull, I feel very certain that the difference must have exceeded the normal limits greatly; more than sufficiently so, in fact, to constitute an anomaly. They neglected to do this. Another omission was the neglect to measure the skull, but as we have a cast of the

prisoner's head taken during his lifetime, and the skull will probably be secured for the Army Medical Museum, this can be practically rectified. As to the actual facts obtained at the autopsy, they seem to me to fall into two classes. The first are those indicating anatomical peculiarities, the second those of a strictly pathological character. Dr. Lamb, as well as Dr. Morton, in their separate reports agree that the right half of the skull was less developed than the left, that the gyri were grossly asymmetrical, the left side being considerably better developed than the right, and some of the fissures on both sides showing unusual features. The opaque and yellow spots in the arachnoid, and the thickening of the dura mater, as well as its adhesion to the skull, are evidences of brain disease. I do not look upon them as the cause of Guiteau's insanity, but rather as belonging to that class of lesions, found so much more frequently in the insane asylum than in the general hospital, which are results of insanity, whether of repeated fluxionary hyperæmias or not others may determine. The inequality of the skull, brain halves, and the atyp of the gyri, are to my mind consistent with Guiteau's clinical history; he was born with that brain, as he was born with his insane tendencies. The defect in his speech, and the defect in the innervation of his left facial muscles, are all evidences of an early irregularity of innervation. The importance of these physical symptoms, as of the anatomical peculiarities noted, lies in their similarity to the findings in the authenticated cases of "Originaire Vermecktheit" of the Germans (original monomania, with systemised delusions), recorded in literature. My evidence on the stand to this effect is borne out by the post-mortem record. As to the inflammatory signs, I look upon them as complicatory and unessential. They might perhaps serve as a support to the view of Dr. Folsom that, in addition to the form of insanity which I believe Guiteau to have suffered from, parietic dementia was beginning to show itself as a complication. I would briefly summarise the matter by saying that if nothing abnormal had been found in Guiteau's brain, it would not have proven his sanity, because in many insane brains no lesions can be detected, while the findings now recorded do not positively prove his insanity, though they point to it as positively as any findings in the insane brain ever can point to mental disease, if we except cases of insanity with paralysis. Taking the matter as a whole, it must be insisted that there is a remarkable harmony between the post-mortem findings and Guiteau's life-history in the light of our present knowledge of insanity.

While on the subject of insanity I can state that the latest returns show that the ratio of insane to the sane in the United States has more than doubled during the last ten years. In 1870 the insane population amounted to 37,442, the ratio being 1 to 1100. In 1880 the number was estimated to be from 89,000 to 96,000, which gives a ratio of 1 to 570 to 1 in 520 of the whole population. Forty million dollars are invested in insane asylums, the average cost of these institutions being half a million dollars each, including interest on capital; the annual expenditure is 12,000,000 dollars for the care of the insane. The accommodation is quite inadequate for the insane in this country. At the present time 74 State and 14 large private asylums exist, having an approximate capacity for about 32,000 persons, but really holding nearly 40,000 patients. These institutions were therefore crowded to the extent of 8000 persons, while about 50,000 lunatics are unable to obtain admittance. Arkansas, with a million of inhabitants, has no asylum whatever; Texas has accommodation for one-fifth of its insane. Pitiable are the accounts of the manner in which the non-asylum insane are treated in the South. Daily complaints show that these unfortunates are stowed away in gaols, workhouses, and with those who farm the poor, and are treated with neglect and inhumanity. Our State Legislatures are warned that before many years the New England and middle States will have an insanity ratio of at least 1 to 350, the Western States the same, and the Southern States 1 to 500 or 600. If they would do what is understood to be done for the insane in England, they must find accommodation for at least three-fourths of such persons. With such a rapid increase of the insane population, it is noticed with regret that slow progress is made towards a thorough comprehension of mental disorders and diseases of the brain. Three hundred physicians are in charge of the United States insane asylums, who have exclusive opportunities of studying the science of psychiatry upon their 40,000 patients. But, as a rule, they contribute nothing of real value to the literature of

the subject. I think such a state of things is unparalleled in any other civilised country in any other medical speciality. I find in one report an exposition of the exploded theories of phrenology, in another an elegant plea for 20,000 raspberry bushes, while in a third a petition is made to the Legislature for a stone; but I look in vain for any demand for a microscope, or any report of any scientific work showing a scientific spirit or a humanitarian interest in the care and treatment of the insane under their charge. In justice to many able men in charge of these establishments, an acknowledgment is due to them for their conscientious efforts to prove good superintendents; I would like to see in the future stronger evidence that they are studious physicians.

July 8th, 1882.

## HYPNOTISM IN PARIS.

(From an occasional Correspondent.)

### No. III.

WE have seen that the manoeuvres employed by mesmerists were capable of inducing a kind of sleep which assumed the different forms of somnambulism, ecstasy, and catalepsy. These states are produced under the influence of an imaginary agent or fluid, to which the name of animal magnetism has been given, and which in certain conditions is said to be transmissible from one person to another. Similar in its results to mesmerism is hypnotism, which Mr. Braid, of Manchester, was the first to bring to notice more than forty years ago. According to this gentleman, hypnotism is capable of effecting more good than can be accomplished by the ordinary mesmerising processes, and it was produced not by any moral agency, as is the case with mesmerism, but by a direct influence on the subject to be experimented upon. The process employed by Mr. Braid to induce sleep was to hold any small object about ten or twelve inches above the middle of the forehead, so as to require a slight exertion of the attention to enable the subject to maintain a steady, fixed gaze on the object. The subject may be either sitting or standing, and he is requested to engage his attention as much as possible on the object he is looking at, and yield to the tendency of sleep which will steal over him in the course of about three or four minutes, and which manifests itself by insensibility and the tendency of the subject to remain in a given position. Thenceforward this process received the name of "neuro-hypnotism," or, as it is also termed, *Braidism*, to distinguish it from that produced by animal magnetism. Strange to say, the writings of Mr. Braid on the subject did not excite much attention in England, but this new form of magnetism met with a better, though tardy, reception in France. M. Broca was the first to bring it to official notice in that country, and after having verified the results obtained by this new process, determined to employ it in surgical operations as a kind of anæsthetic. He tried it on a patient, a young woman, on whom he performed a painful operation under the hypnotic state which lasted a quarter of an hour, and, the result being favourable, he submitted the case to the Academy of Sciences on December 5th, 1859. It is evident, however, that the impression produced by subsequent trials was not sufficiently favourable to warrant its being adopted as a therapeutic agent; for Broca himself abandoned it, and no more notice was taken of it, at least in scientific circles, until recently, when it was revived by Dr. Dumontpallier and Professor Charcot on the one hand, and by M. Donato, a public magnetiser, on the other. The readers of THE LANCET will recollect the experiments performed by Professor Charcot at the Salpêtrière Hospital, which he began about four or five years ago, and which were reported in most of the medical journals in this country and elsewhere. On one occasion he gave a regular "séance" at the hospital, in the presence of Gambetta and other political celebrities, when he made the patients, all females, fall into convulsions, jump, dance, laugh, cry; and he produced other phenomena which one may witness any day at the "salle de conférence" of M. Donato, who is not a medical man. I have seen the latter obtain the most extraordinary results from subjects he had hypnotised. He discards the term "mesmerism," as his mode of proceeding is different from that practised by Mesmer and his followers. Professor Charcot produced

hypnotism by a process somewhat different from that adopted by Braid; but only in form, as the result was exactly the same. Instead of getting the patient to fix her eyes on an object held over her forehead, Professor Charcot began by placing her before a strong light, such as a Drummond's or an electric light, at which she was desired to gaze. In a few minutes or seconds, or sometimes instantaneously, the patient fell into a sort of sleep, termed "hypnotism," which, according to M. Charcot, is a state absolutely different from natural sleep, and is perfectly typified in cases of hystero-epilepsy, in which there is a complex condition of the nervous system, to which the terms "cataleptic," "lethargic," and "somnambulist" have been applied. In a paper read before the Academy of Sciences in February last, and which was presented in support of his candidatureship, Professor Charcot stated that each of these conditions was distinguishable by a symptomatology of its own. The cataleptic state may manifest itself primitively under the influence of a great noise, a bright light placed in front of the patient, or the prolonged gazing at an object. In this state the patient remains immovable; with the eyes wide open, and will so remain as long as the object that excited it continues before her eyes. The limbs preserve for a long time the attitudes given them; when moved they give the sensation of great lightness. The joints offer no resistance whatever, and the reflex action of the tendons is more or less abolished. The respiration is extremely slow, as indicated by the pneumograph. The persistence of sensorial activity in the patient permits the operator to produce, by what Braid termed "suggestion," various automatic phenomena, which, however, are not peculiar to the cataleptic condition, as we shall see further on. The mere closing of the eyelids, or placing the patient in a dark room, is sufficient to transform this state into that of lethargy. The latter state may also be induced by the operator fixing his gaze on the patient's eyes. In this lethargic state the eyelids are closed, and the globes of the eyes convulsed. The body is sunk down on itself, the limbs are relaxed, and the respiratory movements, studied with the aid of the pneumograph, are found to be deep and precipitous, but otherwise regular. The reflex action of the tendons is always exaggerated to a remarkable degree, and M. Charcot has noticed that the muscles are readily brought into a state of contraction by the application of a mechanical stimulus to the tendons, to the muscles themselves, or to the nerves by which they are supplied. M. Charcot has given to this phenomenon the name of "hyperexcitabilité neuro-musculaire." During the whole time that the lethargic state lasts the operator can reduce the contraction thus produced on applying the stimulus to the muscles antagonistic to those contracted; but if the stimulus be limited to the surface of the skin no effect whatever results, whether in producing contraction of the muscles or reducing them when contracted. In the lethargic state any attempts to produce any effect on the patient by way of intimidation or by suggestion are generally fruitless. The somnambulist state may be induced directly by the gaze of the operator or by slight sensorial excitation, often repeated and monotonous. It may be produced in subjects already plunged in a lethargic or cataleptic state by slight friction over the vertex. The patient in this condition has her eyes closed, and if left to herself, she has the appearance of a person in a state of artificial stupor rather than that of normal sleep. The resolution of the limbs is never well marked, the reflex power of the tendons is normal, and the neuro-muscular hyperexcitability described above is *nil* in this case. On the other hand, the slightest excitation of the surface of the skin produces rigidity of the limb, which differs from the contraction connected with neuro-muscular hyperexcitability in that it does not yield, as is the case with this latter condition, to the mechanical excitation of the antagonistic muscles, whereas it yields readily to the influence of the slight cutaneous excitation that gave rise to it. In this state it is generally easy to get the patient to go through automatic exercises of the most complicated and varied character by simple word of command. By slight pressure over the globes of the eyes, the lethargic state is converted into the somnambulist state; if, on the other hand, the eyelids be separated and be kept open in a lighted room, the cataleptic state is not produced. From this it may be inferred that the connexion is more direct between the lethargic and somnambulist states than it is between the latter and the cataleptic state. Such are the results said to have been obtained under the

influence of hypnotism by Professor Charcot; but he admits that, generally speaking, the boundary line of the different phenomena is not so distinctly marked as one would be led to infer from the description given above, as one state runs into the other, and he scouts the idea of these different manifestations of hystero-epilepsy being attributed to simulation or fraud. There is, however, one thing certain, and that is, that hypnotism and animal magnetism or mesmerism are one and the same thing, and that they are produced by manœuvres differing only in form. In the earlier days of mesmerism the phenomena produced were ascribed to a peculiar fluid, which under certain conditions was readily transmissible from one individual to another. Later on the phenomena were ascribed to the effects of the imagination, or, to speak more correctly, the phenomena were produced through the imagination, or through the nervous system. That the latter was the true medium is accepted as the current explanation of the day; and, indeed, Dr. Dumontpallier, in a paper he read before the Academy of Sciences in March last, defines hypnotism to be "a peculiar nervous state, the existence of which cannot be denied in the actual state of science. Comparative experimental physiology has, in fact, admitted its reality by showing the great inconveniences that may arise from its persistence, or too frequent occurrence, in man and animals." This admission by Dr. Dumontpallier was made after a very important paper read by Milne-Edwards, the celebrated biologist, at the Academy of Sciences in February last, and the note of Dr. Dumontpallier referred to was doubtless intended as a rejoinder to Milne-Edwards' paper, the title of which was the "Effects of Hypnosis on Animals." The following is a short extract from Milne-Edwards' paper, which was preceded by a note from Professor Harting of the University of Utrecht. Professor Harting states that after some experiments he had performed some years ago on certain animals, such as the common fowl, pigeons, rabbits, guinea-pigs, frogs, &c., which had been hypnotised in the usual way, he has come to the conclusion that if hypnotisation be frequently repeated on the same subject, its nervous system will be very much shaken. He submitted six fowls to hypnotisation at intervals of two or three days; at the end of about three weeks one of the fowls began to limp, soon after which hemiplegia declared itself, and the animal died. The same thing happened to five other fowls. They were all affected with hemiplegia, one after the other, though at different intervals. In three months all the fowls died. These facts, added the learned Professor, ought to make one very cautious in applying hypnotism to human subjects. M. Milne-Edwards repeated the experiments performed by Professor Harting on mammiferous animals as well as on birds, and, *a priori*, he concludes that if the same phenomena were frequently evoked in hysterical women as those produced in the fowls, their health must eventually suffer. Moreover, after further researches on the subject, he had reason to believe that persons frequently submitted to such influences gradually perfected themselves as "subjects of demonstration." This would appear to point to the fact that by habituating the functions of the nervous system to a pathological routine, the evil becomes aggravated. Whence the deduction that hypnotisation or other analogous performances should never be practised on hysterical subjects. By a curious coincidence this paper was read just before Professor Charcot submitted his thesis at the same meeting of the Academy, already referred to, and the title of which was "Researches on Hypnotisation in the Hysterical." Milne-Edwards' paper would serve as a reply by anticipation; but Dr. Dumontpallier again took up the subject, and in the paper he read before the Academy of Sciences in March last, already referred to, and entitled "Rules to be observed in the Hypnotisation of the Hysterical," resolved to explain the method to be adopted to prevent any inconvenience that may be apprehended in the determination of the different periods of hypnotism. The following is a brief summary of that paper:—"In an hysterical subject, the upper lids being lowered, the rubbing of the globes of the eyes may at once produce lethargy, and this state may be maintained so long as the eyes are kept closed; but the renewed rubbing of the eyes makes the lethargic state cease, and rouses the patient. The cataleptic period may be obtained at once by reflected sunlight, directed over the open eyes of the subject. This period persists as long as the upper lid is kept raised. In renewing the same manœuvre the catalepsy disappears, and the patient is awakened. The period of somnambulism is obtained at once by light pressure on the vertex. The same

pressure renewed will rouse the subject from the state by which the latter was produced. In all these experiments," adds Dr. Dumontpallier, "it is possible to pass the subject from one period to the other by making use of each of the processes detailed above, and commencing by such other phasis as the operator may desire. The states produced should be made to disappear in the order just the reverse of that of their production in employing the means that gave rise to them." Dr. Dumontpallier did not attempt to explain how these different phenomena were produced, but suggested that if any of the members present would wish to assure themselves of the reality of the phenomena, they had only to find a hypnotisable subject. This, however, is no response to the statements made by M. Milne-Edwards concerning the danger of making hypnotic experiments on the human subject; and I am not aware that Professor Charcot has made any since the thesis he read at the Academy of Sciences already adverted to, but which, however, could scarcely be considered a reply.

At a meeting of the Biological Society, held some time previously, Professor Charcot read a paper on the phenomena resulting from the application of a galvanic current to the upper part of the cranium during the lethargic period of hypnotism in hysterical patients. During this period, according to M. Charcot, there exists a state of neurotic hyperexcitability which extends not only to the muscles and nerves, but to the motor regions of the cerebral centre. This state of hyperexcitability is manifested by sudden muscular starts in the face and limbs on the side opposite to that to which the electrodes are applied, but the results are negative when the same experiments are repeated whilst the patient is awake. How the current passes through the bones of the cranium is a question which M. Charcot does not attempt to solve for the moment, but submits it to the consideration of his colleagues. Whereupon M. Dumontpallier endeavoured to show that it was difficult to limit to a point on the surface of the cranium and of the cerebral mass the action of four to ten elements of the battery employed by Professor Charcot (Leclanché's), and he found that the prick of a pin on a limited spot on the scalp was sufficient to determine varied movements, more or less extensive, in the limbs and in the face, which he explained by the irritation being produced at a point corresponding to the motor zones of the cortical substance of the brain. Dr. Dumontpallier produced similar phenomena by blowing through a capillary tube on different regions of the scalp. These experiments were performed on an hysterical patient before the Biological Society, the results of which, he said, were exactly similar to those he had previously obtained in more than fifty other hysterical patients in his hospital wards, and the results have always borne the same relation with the regions irritated. The members present at the meeting were visibly amazed at what they had just witnessed, and naturally endeavoured to elicit some explanation; but all they could get from their colleague was, "J'ai montré des faits, je n'ai rien à ajouter." Donato could hardly have said less. Dumontpallier, however, anxious to impress on his colleagues the importance he attached to his experiments, summed up his paper thus:—"In the different periods of hypnotism it is possible, through the means of an agent specially adapted, to limit on the surface of the scalp a certain number of reflexogenetic zones (*zones réflexogènes*) the irritation of which determines movements in different parts of the body. Some of these zones seem to correspond by their position to the cortical motor regions of the encephalon. The application of several other agents, most varied in their nature, has produced the same results. These agents are—feeble continued electric currents, the loadstone, heat, light, sound; and the hypothesis of their mode of action was more than justified by previous experiments, in which these agents produced aphasia, loss of notion of the use of ordinary objects, and loss of the faculty of reckoning." But, as already stated, Dr. Dumontpallier does not attempt to give any explanation as to the mode of action of these different agents. How they act through the bones of the cranium is a question he is unable to solve at present, and leaves it to his colleagues to form their deductions from what they had seen and read on the subject. I may, however, observe that there is something so unphysiological in all the experiments described above, or rather in the results alleged to have been obtained, that were it not for the high professional status of the experimenters, the investigations would hardly be deserving of serious notice. In fact, M. Donato, the public magnetiser already alluded to, has obtained

the same results, as may be witnessed at his public "séances," or *conférences*, as he pleased to call them, to give them more the character of scientific meetings. He even goes further than Drs. Charcot and Dumontpallier, and pretends to have the power of paralysing or rendering insensible during the magnetic state the special senses, the nerves, muscles, the different organs, either singly or in groups, without having himself the slightest notion of anatomy or physiology. In other words, he professes to paralyse functions, and not organs, which, he says, is quite another phase of this new form of animal magnetism. So it is with a vengeance; and if anyone will unravel this very unphysiological and withal incomprehensible problem, he will deserve well of humanity; as M. Donato, like his more learned rivals, tells his audience: "J'ai montré les faits, je ne peux pas les expliquer." M. Donato—who, by the way, is a Frenchman, and not an Italian, as his name, which is only an assumed one, would lead one to suppose—objects to the term hypnotism, or sleep, as a person "hypnotised" has neither the expression, the behaviour, the physiognomy, the movements, nor the general aspect of a person in a normal condition; and, for want of a better term, he calls it "l'état magnétique."

### AIX LES BAINS, SAVOY.

(From our *Roving Correspondent*.)

FRANCE, according to that eminent balneologist, Dr. Constantin James, contains within its borders a richer and more varied supply of mineral springs and hydrotherapeutic health-resorts than any other country in Europe. Not the least important and valuable of these, although at the same time it is the most recent acquisition, is Aix les Bains, which just now is in the high tide of popular favour not only in France but also in England and other European States, by that numerous and ever-widening circle of health- and pleasure-seekers, who are to be met with in such localities. How much the reputation of Aix is due to its sulphur springs, and how much to its charming situation, to its excellent hotels and public gardens, and to the pleasant, cheery life and amusing manners and ways of the French people of the district, it would be difficult to say. This, however, is indisputable, that excellent therapeutic results are obtained from a residence at Aix in a variety of chronic ailments, especially those of a rheumatic and gouty nature, and that few people are to be found who have once visited Aix either as patients or pleasure-seekers who would not gladly pay it a second or third visit. The waters spring from the earth at a temperature of 113° F., and are rich in sulphates of soda, magnesia, and alumina, fluoride of calcium, and carbonate of lime, with much free carbonic acid and nitrogen. The hot baths and douches and the subsequent shampooing, which is admirably carried out, tend to accelerate the circulation and to incite to activity the latent forces of the body. They are therefore useful in chronic joint affections, sciatica, secondary syphilis, and in lymphatic and glandular enlargements in those of a strumous habit. In addition to the exciting or stimulating effects derived from the hot bath and douche medication there is a tonic or sedative method of treatment, which consists in the use of lukewarm baths and douches, by inhalation of sulphurous gas, and by drinking the sulphurous water. The piscines in which the patients bathe will accommodate from twenty to forty persons; there is no swaddling after it. A sedan chair is not required to take you back to your hotel, but you are quickly dried with warm towels by an attendant, and then allowed to walk home. This system is suited to cases of bronchitis and tuberculosis of the lungs in an early stage, as well as to rheumatic, to scaly and papular skin diseases, such as psoriasis and lichen.

The establishment is one of the handsomest in Europe, and contains twenty-five spacious rooms for the douches, thirty-two private bath-rooms, four large piscines or swimming-baths, besides numerous apartments in which inhalation, "douche de siège," "douche en cercle," and other local baths are carried out; while in the basement are also small chambers where the heat and sulphurous fumes are so overpowering that they are well called "douche d'enfer." The supply of water is computed at a million gallons a day, and 1200 baths, 2000 douches, and 200 inhalations are

administered daily during the season, which lasts from the beginning of May to the middle of October. Numerous physicians of eminence may be consulted at the establishment, or at their own chambers, and without their instructions no one should submit himself to a course of baths.

The therapeutic value of the waters of Aix is best seen in rheumatism, arthritis or osteo-arthritis, and in muscular pains or in sciatica. In such cases Dr. Garrod recommends Aix in preference to Turkish baths; and Dr. Robert Adams, in his treatise on rheumatic gout, also speaks highly in its favour. Dr. Garrod says, "I have seen numerous cases of rheumatoid arthritis, in its earlier stage, most signally benefited by this treatment (waters of Aix, Marlioz, or Challes), and in several the disease seemed to have been entirely arrested. The treatment is also peculiarly valuable when there has been any skin complication—e.g., eczema or psoriasis. Sir Dominic Corrigan came to Aix in 1875 to be cured of some gouty stiffness and puffiness in the joints of the lower extremity, and, in writing to Dr. Bertin, in April, 1876, to introduce another patient, he says, "Thanks to you and Aix les Bains, I am now quite well." The works of Dr. Bertin, Brachet, and Cazalis will give ample information as to the special effects of using sulphur baths and of drinking the mineral waters of Aix.

In the immediate vicinity of Aix are two other sulphur springs, Marlioz and Challes, each of which has special merits and deserves notice. Marlioz has water highly charged with sulphur and soda, and also slightly with iodine and bromine. It is nearly a mile from Aix, and stands in a handsome park. The water issues at 57° F., and at the rate of 1400 gallons a day. There is a fine pump room, two inhalation rooms, nine private bath rooms, a cold douche, two ascending douches, &c. Challes is three miles from Chambéry. The temperature of the water is 53° F. It is 935 feet above sea-level, and its springs are very rich in sulphide of sodium. Aix is fourteen hours from Paris, on the direct railway to Turin, there being two express trains a day. It was celebrated in the time of Domitian, in whose day the Roman arch (Arch of Campanus) now standing in front of the bathing establishment was probably erected.

In 1784 Victor Amadeus III. sojourned at Aix, and about that date the thermal establishment was commenced, but its great development dates from the time when Savoy was handed over to France, after the battle of Solferino. The Government has erected a hospital for poor bathers, and has also provided the town with a fine park. Aix is prettily situated at the base of Mount Revard, 850 feet above sea-level, and is one mile from the picturesque lake Bourget. Its hotels are large and commodious. There is a fine assembly and also a reading-room, in which all the leading European papers are to be found. Many excellent excursions can be made on the lake, as to Haute Combe at the foot of the Dent du Chat, where are the tombs of the princes of Savoy. Those who can spare the time should visit the lake of Annecy, the Gorge de Fier, the monastery of the Grande Chartreuse, and make the ascent of the Seinnos or Rigi of Savoy, by each and all of which they will be amply repaid.

### MEDICAL NOTES IN PARLIAMENT.

In the House of Commons, on Friday, July 21st, a petition was presented from the South-Eastern Branch of the British Medical Association, praying for redress of the grievances of militia surgeons. On the motion of Mr. Round, a return was ordered of the number and cost of pauper lunatics in county and borough asylums in the three kingdoms. On Saturday and Monday further petitions were presented re the grievances of militia surgeons. The Union Officers' Superannuation (Ireland) Bill was read a second time on Saturday. On Monday, the twenty-fourth report of the Board of Superintendence of Dublin Hospitals was presented.

#### *Ventilation of the Houses of Parliament.*

On Tuesday, Mr. O'Shea asked the First Commissioner of Works whether complaints had reached him of defective ventilation and noxious exhalations in and about the House; and, if so, whether he would have the nuisance abated.

Mr. Shaw Lefevre read a report which he had received from Dr. Percy. The latter stated that during the seventeen years he had had charge of the ventilation of the Houses of Parliament many complaints had been made of unpleasant

smells. In every case he found they were caused by contamination of the air outside, sometimes at a considerable distance from the House, the wind blowing the contaminated air in the direction of the building. It was not possible to prevent such smells in the House when the air outside was so impregnated. Some of the unpleasantness lately had arisen from the tar which the wood pavement in the neighbouring thoroughfares was covered. No sewage gas could possibly escape from the drains under the building, as they were exhausted, and the gas allowed to escape at the top of the tower. The Chairman of Committee, who was a scientific man, and, as he himself said, peculiarly sensitive to smells, informed him that he thought on the whole the ventilation of the House within the past few months had been maintained exceptionally well.

#### *Belfast Workhouse.*

On Wednesday, Mr. Biggar gave notice of a series of questions imputing grave neglect of duty to the master of the Belfast workhouse, who it was alleged had refused admission late at night to three persons bearing orders marked "urgent," and they were found by the police lying at the workhouse gate. It was stated that one of the three was an old man, seventy years of age, who was suffering from a severe attack of hæmorrhage; and another was an old woman of sixty-seven. It appeared that complaint had been made of previous cases, and also that the guardians had approved the conduct of the master; and Mr. Biggar intends to ask, if these allegations are true, what steps will be taken by the Local Government Board.

#### *Carlow Workhouse.*

Mr. A. O'Connor put upon the paper three questions with regard to this workhouse. They refer mainly to the conduct of the chairman of the board of guardians, who is accused of having acted without the authority of the board in ordering additional works connected with the workhouse and infirmary; but the third question is as follows: "Whether Dr. Rawson, the medical officer, who also attends the soldiers stationed at Carlow, has on several occasions introduced into the workhouse for treatment soldiers suffering from loathsome skin and other affections; and if so, whether the Chief Secretary intends to take any notice of the practice."

#### *Vaccination Questions.*

On Thursday, Mr. P. A. Taylor inquired of the Home Secretary whether it was true that Mr. James Burman, of Derby, who had been sentenced to seven days' imprisonment for refusing to have his child vaccinated, was compelled to sleep on a plank bed, was refused sufficient clothing by day to prevent his suffering from cold, and was compelled to pick oakum, although hard labour was not a part of the sentence.—Sir W. Harcourt said he had inquired into the case, and found that nothing was done which was not in strict accordance with the prison rules.

Mr. Taylor also asked the President of the Local Government Board whether he had received any report in reference to the vaccination fatality at Norwich, and, if so, whether he proposed to have it printed; whether he had ascertained the description of lymph used upon the occasion; and whether he had forbidden the use in future of similar lymph.—Mr. Dodson said he had not yet received the report of the inspector, and therefore was unable to give the hon. member the information he asked for.

#### *The Expedition to Egypt.*

In the debate on the vote of credit, Mr. Childers stated that the sanitary arrangements for the expedition had been very carefully studied. Whilst extravagance was to be avoided, there could be no worse form of penury than starving those arrangements. Eight field hospitals were being established, and two hospital ships, and two large hospital depôts. A very large staff of doctors was being sent out, with 800 men of the Army Hospital Corps. Every precaution was being taken to preserve the soldiers from ophthalmia, and a body of nurses was being sent for service, not only in the hospitals and depôts, but also in the field. Every arrangement was made to secure a sufficient supply of water for the troops. The question of the best clothing had been duly studied, and the tents were all double, which was a most essential thing in that climate. As to land transport, they had now done what had never been done before—viz., they had sent out an adequate regimental transport with each regiment.

## ROYAL COLLEGE OF PHYSICIANS.

At a meeting of the Fellows, held at the Royal College of Physicians, on Thursday, the 27th inst., the annual reports of the Library Committee and Curators of the Museum were read, and the thanks of the College were given to Dr. Barclay, Dr. Arlidge, and the executrix of the late Dr. Jenks, of Bath, for valuable donations of books. Dr. Sieveking then moved the resolution of which he had already given notice—to wit, "That the system of extensively advertising medical works in non-medical journals, and the custom of giving laudatory certificates of medicinal and other preparations, whether for publication or not, is misleading to the public, derogatory to the dignity of the profession, and contrary to the traditions and resolutions of the Royal College of Physicians." An animated discussion ensued, and several amendments were suggested and withdrawn. Ultimately the original resolution, with the omission of the words "in non-medical journals," and the insertion of "and medical and surgical appliances" after the words "other preparations," was carried by a large majority.

The election of officers was as follows:—Censors: Drs. Munk, Andrew Clark, Lionel Beale, and Pavy. Treasurer: Dr. Farre. Registrar: Dr. Pitman. Harveian Librarian: Dr. Munk. Curators of the Museum: Drs. Wegg, Lionel Beale, Reginald Southey, and John Curnow.

## Obituary.

### THOMAS BARBOUR MOFFAT, M.D. ST. AND.

DR. MOFFAT, whose death took place on the 16th inst. from cancer of the pylorus, was a well-known and highly respected practitioner at Hawarden in Flintshire for the last forty-five years. He came of a respectable old family, the Moffats of Sundaywell and Stroquhan, in Dumfriesshire, where he was born in 1813. He studied at Edinburgh, where he took his surgeon's diploma in 1836. Shortly afterwards he came to Hawarden as assistant to Mr. Probart, surgeon there, to whose practice he soon succeeded. In 1842 he took his M.D. degree at St. Andrews. He was a Fellow of the Geological Society and of the Sanitary Institution; Member of the Epidemiological and of several other scientific societies, and author of many papers on geology, meteorology, and sanitation, &c. Although of considerable professional and scientific ability, he was content to find his calling in a hard country practice rather than cultivate a more wealthy clientèle in one of our larger towns. Though a man of strong individuality of character, yet his cheerful disposition and ready sympathy won him the respect and friendship of nearly all who came in contact with him, and his death is greatly regretted. As he did a large amount of work for little pecuniary remuneration, he did not leave much of this world's goods behind him. He is survived by his widow, six sons, and three daughters.

## Medical News.

### ROYAL COLLEGE OF SURGEONS OF ENGLAND.—

The following gentlemen, having passed the required examination for the Diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 20th inst.:—

Birch, Henry Priestley, Harley-street.  
Carlyon, Edward Trewbody, Truro.  
Fenner, Robert Nathaniel, Greenwich.  
Knight, Frederick, Swansea.  
Russell, Robert Hamilton, Farnham.  
Sheppard, William John, Putney.  
Thring, Edward Thomas, Birkenhead.  
Tresidder, Edward Stanley, Dulwich.  
Williams, Edward Richard, Corwen.  
Wilson, Mervyn Seppings, Kilburn.

The following gentlemen were admitted Members of the College on the 21st inst.:—

Back, Herbert Hatfield, Hethersett, Norfolk.  
Barber, Alfred, Basingstoke.  
Berry, James, Upper Bedford-place.

Blagg, Arthur Frederick, Crowndale-road.  
 Bollen, Frederick James, Port Adelaide.  
 Frost, George, Dorking.  
 Howell, James Bromley, Wandsworth.  
 Marsh, Nicholas Percy, Liverpool.  
 Maude, Arthur, Highgate.  
 Nicholson, Robert Howard, Ilfracombe.  
 Skipper, Edward, Dulston.  
 Viney, Josiah Ernest, M.B. Cantab., Highgate.

The following gentlemen were admitted Members of the College on the 24th inst.:—

Anderson, Alfred Jasper, Blackpool.  
 Carr, Thomas, Brixton.  
 Claremont, Louis Bennett, Camden Town.  
 Davies, W. T. Frederick, Swansea.  
 Eastes, Frederick, Folkestone.  
 Elgoed, Charles Reginald, Wisbeach.  
 Gibson, John Hutchinson, Trinity-square.  
 Herr, William, Ashburton, Devon.  
 Jacob, Arthur Howard, Surbiton.  
 Jones, Isalah Henry, Malda Vale.  
 Quick, Frank, Coventry.  
 Toller, C. W. Edward, L.R.C.P. Lond., Wimbledon.  
 White, Ernest Alfred, Leeds.

The following gentlemen were admitted Members of the College on the 25th inst.:—

Banatvala, Hormasjee Edaljee, L.R.C.P. Lond., Bombay.  
 Campbell, Samuel George, Natal.  
 Gordon, Edward, L.S.A., Stockport.  
 Gracie, Charles Batten, Liverpool.  
 Freeborn, J. C. Richard, Oxford.  
 Harratt, Henry, Brixton.  
 Kelly, Charles Augustus, Mount-street.  
 Lilly, Frederick John, Southampton.  
 Spong, William, Clapham.  
 Thomas, John Lloyd, L.S.A., Beaumaris.

The following gentlemen were admitted Members of the College on the 26th inst.:—

Benjafield, William Barnett, M.B. Edin., Leatherhead.  
 Beverley, John Metcalfe, L.S.A., Bury, Lancashire.  
 Fowler, Charles Owen, L.S.A., Hereford.  
 Massey, Henry Massey, Camberwell.  
 Peacock, Robert Knox, M.B. Edin., Oldham.  
 Pryce, Thos. Davies, Newtown, Montgomeryshire.  
 Wilson, Reginald William, Rotherhithe.  
 Willcocks, Arthur Durant, L.S.A., Kensington.  
 Willcox, Ernest, M.B. Edin., St. Neots.

[In the list of students who passed the Primary Examination at the College on the 13th inst., Mr. T. A. B. Soden should have been described as belonging to Charing-cross Hospital.]

**ROYAL UNIVERSITY OF IRELAND.**—The following have passed the First Examination in Medicine of the University:—

Robert James Boyd, Roger Bernard Burke, P. J. Cahill, Thomas Callaghan, David Clarke Campbell, Kenneth J. Campbell, William Henry Carisle, P. J. Cleary, Richard T. Condon, Alexander Corry, Thomas B. Costello, Joseph Cree, Henry Alfred Cummins, J. E. Curtin, Charles A. Daly, Thomas J. Daly, M. P. Dunlea, William Henry Davis, William Demery, J. J. Donnellan, John Francis Eagleton, Thomas Joseph Enright, George Francis Ewens, Edward Fitzgerald Flood, Maurice Foley, Bernard Forde, John Frederick Gordon, Geo. R. Graham, John E. Haines, Henry Harley, Samuel Horneck, John William Irwin, Thomas Kiernan, Daniel T. Lane, Richard Whytock Leslie, Thomas Lusk, Neal M'Bride, Michael M'Carthy, David M'Kee, P. M'Sheffrey, Charles J. Macdonald, Thomas Stephen Mac Mahon, Jas. Richard Mangan, John Meenan, William Milligan, Martin Moloney, Frederick V. Moesman, Daniel Murphy, M. J. Murphy, Albert Thos. Nash, Robt. William Nixon, James P. O'Byrne, Joseph O'Connor, Patrick J. O'Hara, Daniel Joseph O'Keefe, P. O'Sullivan, M. J. Robinson, Maurice Slak, Alfred John Smyth, Richd. Henry Spencer, Edwin Alfred Starling, James Simpson Steele, Alfred Edward Thompson, John J. Tobin, Richard Henry Wagner, Hugh Ernest Walde, William Edw. Wales, J. J. Walsh, William A. Whitelegge, James Dunlop Williamson, Alleyn William Wolfe, Robert Inglewood Wolfe, George Nesbitt Wynne, Richard Thomas Young.

**APOTHECARIES' HALL.**—The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on July 20th:—

Black, Wm. Jones, Shetford-road, Manchester.  
 Scanlan, Arthur de Courcy, Hayer-road, Brixton.  
 Slater, William, Poplar Hospital.  
 West, John Arthur, Bickley Park, Kent.

The following gentlemen also on the same day passed the Primary Professional Examination:—

Christopher Venning Burgess, London Hospital; Charles Style Humphreys and Herbert Larder, Westminster Hospital; Alexander Gascoigne Wildey, Guy's Hospital.

**MALVERN COLLEGE.**—We understand that Tuesday, August 1st, is fixed as "Speech Day" at this College.

**ROYAL MEDICAL AND CHIRURGICAL SOCIETY.**—The Library will be closed on Monday, August 7th, and, on account of some extraordinary building repairs, &c., will not reopen till Monday, Sept. 18th next.

**VACCINATION GRANT.**—Mr. A. Megget, of Scarborough, has received the Government grant of £55 4s., for efficient vaccination in his district (fifth time).

**A CONVALESCENT HOME for the West of England** was opened at Weston-super-Mare on Wednesday. The building will contain 100 beds, and has cost over £11,000. At the luncheon following the formal opening a sum of £230 was contributed towards furnishing the institution.

**UCKFIELD COTTAGE HOSPITAL.**—The report of the Committee of Management of this hospital states that of the 26 cases admitted during the past year, 19 had been discharged cured, 5 had derived benefit, and 2 remained in the institution. The mortality therefore was *nil*. The fact that the balance-sheet shows a deficit of £37 is to be regretted.

The Committee of Management of the Royal Aberdeen Lunatic Asylum have been authorised by the Court of the President and Managers of the Royal Infirmary to provide additional accommodation for female lunatics by extending the east wing of the asylum, at an estimated cost of £1600.

At a meeting last week of the managers of the Cotton Districts Convalescent Fund, presided over by Lord Derby, it was decided to transfer a plot of land adjoining the Convalescent Home at Southport, for the purpose of erecting buildings on it which will connect the old and new hospitals, at present isolated.

**THE BAZAAR AT COLSTON HALL, BRISTOL.**—The bazaar opened on the 18th inst. in commemoration of the jubilee of the Bristol General Hospital and in aid of its funds, appears to have more than realised what was expected of it by its promoters. The wealth and fashion of the city vied with the trading and industrial elements to ensure the success of the project, by which it is calculated the funds of the hospital will be enriched to the extent of some £3000.

**RICHMOND HOSPITAL.**—The Duchess of Teck opened new wards at the Richmond Hospital on the 22nd inst. The new buildings form a block 70 ft. in length and 30 ft. in width—exclusive of separate wings for lavatories, bath rooms, &c.,—and rise to a height of over 40 ft. Accompanied by the Duke of Teck and conducted by the medical staff, she made a minute inspection of the wards, and then proceeded to a marquee in the grounds, where she received and briefly responded to an address on behalf of the committee of management, signifying her assent to a proposal that the female ward should be named the Mary Adelaide Ward, and the male ward the Cambridge. Her Royal Highness accepted on behalf of the charity a considerable number of purses, none of them containing less than £5.

**SOUTH LONDON SCHOOL OF PHARMACY.**—The following prizes have been awarded to the successful competitors at the school examinations held on July 4th, 5th, 7th, and 8th. Senior Chemistry: Mr. Caldecot (medal). Junior Chemistry: Mr. T. B. Tyson (medal). Botany: Miss Mitten (medal). Materia Medica: Mr. F. Ransome (medal). Practical Dispensing and Pharmacy: Mr. C. L. Dillon (medal). Senior Chemistry: Mr. Bain (certificate). Junior Chemistry: Mr. F. Ransome (certificate). Botany: Mr. C. E. Harston (certificate). Materia Medica: Mr. C. E. Harston (certificate). Practical Dispensing and Pharmacy: Mr. T. B. Tyson (certificate). Certificates of Merit were also awarded to Messrs. Dowdeswell, Dillon, Hornby, Schofield, Thomas, and Thistleton.

**MANCHESTER ROYAL INFIRMARY.**—At the annual meeting of the friends of this hospital on the 27th inst., the trustees were able to give a more favourable report of the financial condition of the institution than was possible last year, a result attributable mainly to an increase in the ordinary annual subscriptions and in the Hospital Saturday and Sunday contributions. There appears to have been a gradual diminution in the cost per bed occupied: ten years ago this was represented by the sum of £74 11s. 10d.; now it does not exceed £58 7s. 6d. per bed. A similar decrease in expenditure has also characterised the management of the Cheadle Convalescent Hospital. The total number of patients treated at the infirmary and its associate institutions was for the past year 23,888. Investigation continues to be made into the circumstances of all applicants for hospital relief, with, it would seem, on the whole, satisfactory results.

## ROYAL UNIVERSITY OF IRELAND.

EXAMINATION FOR M.D. DEGREE AND DIPLOMA IN OBSTETRICS.  
June 22nd, 1882, 9.30 A.M. to 12.30 P.M.

Examiners { Professor J. A. Byrne, M.D.,  
Professor H. McN. Jones, M.D.

## Section A.

1. Describe the appearance of an ovum expelled in its integrity from the uterus at the nineteenth day of gestation. Describe in order all its coverings in dissecting it from without inwards, and the appearance and structure of each coat, also the contents of the sac and the exact appearance and size of the embryo at this date.

2. Describe the structure of the uterus at the full term of gestation, the mode of arrangement of its muscular fibres, and the function which one set of those fibres is said to serve, as also the functions of the other muscular strata.

3. At the termination of the third month of pregnancy, and at the termination of the full period, two circumstances may happen which are very serious. What are they, and which would you regard as the more serious?

4. Mention all the actors in producing dilatation of the os uteri in labour.

## Section B.

5. What are the principal changes occurring in the blood during pregnancy? State how such deviations are likely to affect the character of a labour.

6. You are called to a woman in the fourth month of pregnancy; there has been severe but periodical hæmorrhage for nearly two days, with expulsion of clots; on making an examination, the os is found slightly dilated. State how you would manage the case.

7. You are called to a woman some hours in labour; there has been severe hæmorrhage; the os uteri is not dilated to the size of a florin; the placental attachment is complete. State how you would conduct the case.

8. You are in attendance on a case in which you have reason to apprehend the occurrence of post-partum hæmorrhage. What preventive measures would you adopt? Should these fail, mention in order the steps you would take to control it.

In the Oral Examination, on the same day, Dr. Byrne asked—(1) Describe the treatment of ruptured uterus in two words. (2) What is concealed hæmorrhage, and where does it occur? and gave a number of obstetric instruments to have their uses, &c., explained.

## GYNÆCOLOGY.

## Section A.

1. Describe the different treatments of pelvic cellulitis; describe also the anatomical relations of the uterus to the surrounding organs which may influence each particular mode of exit when purulent formation is the result.

2. How would you distinguish between chronic inverted uteri and polypus uteri? What are the causes of the former affection? What would be your treatment of each?

## Section B.

3. Mention the symptoms, course, and treatment of pelvic hæmatocele.  
4. Ovarian tumour, fibro-cyst of uterus, ascites. State the leading diagnostic tests to distinguish each.

## Medical Appointments.

Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning at the latest.

BOISSIER, ARTHUR HENRY, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the First Pocklington District of the Pocklington Union.

COLEMAN, MATTHEW OWEN, M.D. Aber., M.R.C.S., has been re-appointed Medical Officer of Health to the Sribiton Urban Sanitary District.

COOPER, G. F., M.R.C.S., L.R.C.P., has been appointed Resident Accoucheur to St. Thomas's Hospital.

DUNCAN, W. A., M.D., L.R.C.P., M.R.C.S., has been appointed House-Surgeon to St. Thomas's Hospital.

DYER, HENRY GEARY, M.R.C.S., L.R.C.P. Ed., has been appointed Medical Officer to the Ringwood Union and Workhouse, vice Samuel S. Dyer, M.D., resigned.

EVANS, FREDERICK WM., M.D., M.R.C.S., L.S.A. Lond., has been appointed Certifying Factory Surgeon for the Cardiff District, vice H. J. Paine, M.D., M.R.C.S., resigned.

FELL, W., M.A., M.B. Oxon., L.R.C.P., M.R.C.S., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

GIMSON, WILLIAM GIMSON, M.D. St. And., M.R.C.S., L.S.A. Lond., has been appointed Medical Officer for Wickham Bishop's District of the Maldon Union.

GOWAN, CHARLES, M.D., C.M., L.R.C.S. Ed., has been appointed Medical Officer for the Newtown District of the Newtown and Llandiloos Union.

HAG BROWN, C. W., M.R.C.S., L.S.A. Lond., has been appointed House-Surgeon to St. Thomas's Hospital.

HARRIS, ARTHUR G. RAWSON, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Pembroke District of the Kingston Union.

JONES, WANSBROUGH, M.A., M.B. Oxon., B.Sc. Lond., M.R.C.S., has been appointed House-Physician to St. Thomas's Hospital.

MACKENZIE, S. M.B., has been appointed Assistant Medical Officer to the Roxburgh, Berwick, and Selkirk District Asylum, Melrose, vice L. R. Huxtable, M.B., resigned.

MILTON, H. M., M.R.C.S., L.S.A. Lond., has been appointed Assistant House-Physician to St. Thomas's Hospital.

NIXON, CHRISTOPHER JOHN, M.B. Dub., F.K.Q.C.P.I., has been appointed Visiting Physician to the Dandrum Central Criminal Lunatic Asylum, vice Hughes, deceased.

RICH, ARTHUR CRESWELL, M.B. Lond., M.R.C.S., has been appointed a Medical Officer to H.M. Post Office, Liverpool.

THOMPSON, J. A. BAIRD, M.D., C.M. Glas., has been appointed Medical Officer to the Middleton Cheney District of the Banbury Union.

VIVIAN, GEORGE E., M.R.C.S., has been appointed Medical Officer for the Ains District of the Easingwold Union.

WALKER, J. McCLEURE, M.B., C.M. Glas., has been appointed Medical Officer for the Eastern District and Workhouse of the Haltwhistle Union.

WELLS, A. E., L.R.C.P., M.R.C.S., has been appointed House-Physician to St. Thomas's Hospital.

WHITE, EDWARD A., M.D., M.C. Aber., L.S.A. Lond., has been appointed Medical Officer for the Third District of the Malmesbury Union, vice J. C. S. Jennings, F.R.C.S., resigned.

WHITE, E. F., M.R.C.S., L.S.A. Lond., has been appointed House-Physician to St. Thomas's Hospital.

WIGNER, G. W., F.C.S., has been reappointed Public Analyst for the District of Greenwich.

WILLIAMS, CHARLES, L.S.A. Lond., has been appointed Medical Officer for the First District of the Bodmin Union.

WILSON, J. A., M.B., C.M., has been appointed Assistant Medical Officer to the Govan Poorhouse and Asylum, Merryflatts, Govan, vice A. Martin, M.B., resigned.

## Births, Marriages, and Deaths.

## BIRTHS.

BOISSIER.—On the 19th inst., at Oak House, Pocklington, Yorks, the wife of Arthur H. Boissier, L.R.C.P. Lond., M.R.C.S., of a daughter.  
BROWN.—On the 14th inst., at Coombe Lodge, Rye-lane, Peckham, S.E., the wife of J. Alexander Brown, M.R.C.S., of a daughter.

DICKSON.—On the 19th inst., at South View, St. Heller's, Jersey, the wife of John Edward Dickson, M.B., C.M. Ed., of a son.

HARGOOD.—On the 23rd inst., at Stafford House, Eastbourne, the wife of Henry Hargood, M.D., of a son.

MARTIN.—On the 19th inst., at Richmond, Limerick, the wife of Surgeon-Major W. T. Martin, M.D., of a daughter.

MCCREDDY.—On the 11th ult., at Calle Morelos, Pachuca, Hidalgo, Mexico, the wife of Robert H. McCreedy, M.D. &c., of a son.

SHAPTER.—On the 19th inst., at Barnfield-crescent, Exeter, the wife of Lewis Shapter, M.D., of a daughter.

SNOW.—On the 22nd inst., at Bayswater, the wife of Herbert L. Snow, M.D. Lond., of a son.

SYMES.—On the 23rd inst., at Wards End, Halifax, the wife of Edmond West Symes, M.D., of a daughter.

## MARRIAGES.

ALLEN—KING.—On the 21st ult., at St. Cyprian's Church, Durban, Natal, by the Right Rev. the Lord Bishop of Maritzburg, assisted by the Rev. Joseph Taylor, of Richmond, Robert Allen, L.R.C.S.I., L.R.C.P. Ed., &c. &c., of Pietermaritzburg, eldest son of the late Capt. Allen, H.C.S., of Dublin, Ireland, to Clara Elvira (Ella), second daughter of the late Mr. Richard King, of Isipingo, Durban County, Natal.

BRODRICK—CROCKFORD.—On the 20th inst., at the Parish Church, Peasmarsh, Sussex, Charles Cumberland Brodrick, L.R.C.P. and L.R.C.S., son of Charles Cumberland Brodrick, Esq., Paymaster, Royal Navy, to Julia Selina, youngest daughter of Henry Crockford, Esq., of Flackley Ash, Sussex.

HART—BERTHON.—On the 20th inst., at St. Mark's, Woolston, William Hamilton Hart, M.R.C.S., L.S.A., eldest son of J. H. G. Hart C.E., Poona, Bombay, to Frances Elizabeth Margaret, eldest daughter of E. P. Berthon, of Woolston, Southampton.

REES—LEWIS.—On the 14th inst., at St. Mary's Church, Port Elizabeth, Frederick Musson Rees, M.D., J.P., of Bedford, South Africa, to Clara, daughter of W. Lewis, Crews.

RICHARDSON—ETHERIDGE.—On the 13th inst., at the Parish Church, Rain-gate, Thomas William Richardson, M.R.C.S., of Surrey-street, Norwich, to Rose Louise, second daughter of Major-General A. T. Etheridge, C.S.I., late Bombay Staff Corps.

TEMPLETON—ALLEN.—On the 11th inst., at St. John's Church, Malone, R. Scanser, eldest son of Robert Templeton, Esq., Dep. Insp.-Gen., F.R.C.S.I., Cranmore, Belfast, to Jane, eldest daughter of Arthur Chichester Allen, J.P., Collin, county Antrim.

## DEATHS.

ATKINSON.—On the 18th inst., at Broadstairs, John Charles Atkinson, L.R.C.P., M.R.C.S., &c. (son of J. C. Atkinson, M.D., of Kew-green), aged 82.

BARTLEY.—On the 21st inst., at his residence, Norwood House, Weston-super-Mare, Robert T. Hawley Bartley, M.D., late of Clifton, Bristol, aged 62.

CORMACK.—At 364, Rue St. Honoré, Paris, Lady Cormack (Eliza Ann), nee Hine, widow of the late Sir John Ross Cormack, M.D.

HIGHAM.—On the 23rd inst., at Lauderdale House, Northcote-road, Wandsworth, Joseph Higham, Esq., Surgeon, aged 42.

JORDISON.—On the 20th inst., at South Ockendon, Essex, Eliza Frances, widow of Robert Binks Jordison, Surgeon. Friends will please accept this intimation.

OSWALD.—On the 22nd inst., at 215, Kennington-road, London, S.E., Louisa Ann, wife of James W. J. Oswald, M.D., F.R.C.S.E., aged 53.

POPPLETON.—On the 25th inst., at The Grange, Horsforth, Leeds, Joe William Poppleton, F.R.C.S. Lond., for forty years Certifying Surgeon under the Factory Acts for the Bradford District, aged 67.

TAYLOR.—On Feb. 6th, at Goulburn, New South Wales, Charles Lamb Taylor, M.D., eldest son of the late Samuel and Elizabeth Taylor, of Newark-upon-Trent, aged 81.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Notes, Short Comments, and Answers to Correspondents.

*It is especially requested that curly intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*We cannot prescribe, or recommend practitioners.*

*Local papers containing reports or news-paragraphs should be marked.*

*All communications relating to the editorial business of the journal must be addressed "To the Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

### SANITATION AT VENTNOR.

A propos of a criticism that appeared some time ago on the sanitary state of Ventnor, *Medicus*, in a letter addressed to us, remarks:—"Attention having been directed in 1875 to the danger then existing in the town of Ventnor, not only as regarded the want of proper sanitary arrangements, but also the risk incurred from an intermittent and inadequate water-supply, the authorities were roused to take steps for the institution of a house-to-house inspection, but which was unfortunately allowed to fall through before completion, and no further effort was made until the official report of Dr. Ballard, when the authorities, instead of kicking against the inevitable, wisely determined to put their house in order, with the striking result of reducing the death-rate from 28.4 in 1880 to 13.3 in 1881: a return which, after eliminating the number of deaths of those who came to Ventnor as strangers in the last stage of disease, shows the gratifying result that the death-rate of the inhabitants proper amounts only to 9.6 per 1000. . . . The difficulties with which local boards have to contend is not so much in the matter of the main drainage as in the connexions and appliances of private houses. And it would be well were the Legislature to amend in many respects the present Health of Towns Act, and render compulsory a house-to-house inspection, of which a record should be kept by the local authority, and such inspection should be annual. . . . Before leaving the question of sanitary arrangements, I feel bound to mention a circumstance that not only marks the progress of Ventnor, but which must tend to improve it greatly in a sanitary point of view—namely, the erection of a large steam washing establishment. It covers a considerable area, is fitted with all the most recent and approved appliances, and embraces, what is of the highest value, a proper chamber for disinfecting purposes. The establishment would appear large enough not only to supply the wants of Ventnor and its immediate neighbourhood, but also those of the adjoining towns of Shanklin and Sandown. To the public the gain is immense. Instead of the clothes being confined to the manipulation of a single tub, they are passed through several waters, and thus properly cleansed, while the appliances for drying, ironing, mangling, &c., are on a scale that attains a perfection which it is impossible to obtain from the ordinary laundress. The dangers which arise for the spread of disease through the common laundress is well known to every medical man, and I need only instance an occurrence which took place some time since, in which a laundress was detected pinning out some curtains over the bed of a party recovering from scarlet fever while the desquamation of the skin was in its most active form."

### OBSCURE SKIN DISEASE.

*To the Editor of THE LANCET.*

SIR,—I shall feel indebted to any of my medical brethren who will assist me in the diagnosis and treatment of the following case:—

A B—, aged thirty-six, married, healthy constitution, contracted syphilis about twelve years since. Six years subsequently appeared a discolouration of skin, resembling a light walnut stain. Parts principally affected are back and around umbilicus. My patient has been prescribed by some eminent practitioners without avail.

I am, Sir, yours faithfully,

July 25th, 1882.

ENQUIRENS.

### SCENES AT THE HOSPITAL IN ALEXANDRIA.

A CORRESPONDENT of a Liverpool paper thus describes a scene he witnessed in his walks about the Egyptian city:—

"I went up to the Arab hospital recently, with Dr. Bell, of the *Helicon*, and a party of blue jackets, to inspect and take measures for relieving the wounded, whom we had heard were without medical attendance, or even the bare necessities of life. The scene on our arrival more than justified this statement. There were thirty-two wounded, including six women, some in a frightful condition. Most of the poor wretches were suffering from gunshot wounds or shell splinters. Three or four were in a state too horrible to describe. Their wounds had not been dressed for three days, and human aid could avail nothing."

Fairplay is thanked for his communication, but we do not think it would be in the interest of the service to publish it.

F. A. D.—No.

Diploma.—The superintendent of Bethnal House Asylum, Cambridge-road, London.

### THE MEDICAL COUNCIL AND ITS FUNCTIONS.

*To the Editor of THE LANCET.*

SIR,—Your article in last week's LANCET on the dormant powers of the Medical Council will meet, I am sure, the approbation of the right-thinking part of the profession. There is another kindred point I think the Council might also take into their serious consideration. I allude to what takes place—I fear, not uncommonly—in the sale of practices. It seems to me that in many cases common honesty is deliberately set aside and deeds done which in any other section of the community would be visited with the severest reprobation. We call ours a noble profession. Should not this, therefore, be a strong reason why all who wish well to the profession should raise a protest against what I am afraid is a growing evil? I shall be glad if this letter will elicit your views and those of the profession on this subject.

I am, Sir, yours truly,  
X.

July 26th, 1882.

*Medicus* is referred to the article on Books in our Students' Number, Sept. 10th, 1881.

Nemo.—Graily Hewitt, in vols. 1 and 2 of the Obstetrical Transactions.

Dr. Allan Jamieson.—Yes.

Mr. G. Abbott (Tunbridge Wells).—The paper will be inserted as early as possible after receipt of the block.

### DEATH FROM CHLOROFORM.

*To the Editor of THE LANCET.*

SIR,—In reference to your report of the two cases of death from chloroform, I find one was a man of the name of Sidders, operated on at the Canterbury Hospital, from whom I removed, some four or five years ago, one of the great toes, under the influence of chloroform, from the effects of which he soon recovered, and the case terminated most satisfactorily. This, I think, shows that although a person may at one time inhale chloroform with impunity, no one can with certainty say it can be administered a second time without some risk or danger.

I am, Sir, yours obediently,

Folkstone, July 26th, 1882.

ALLEN DUKE.

Thesis.—We have not at hand a list of the subjects for which prizes are offered.

Mr. H. A. Smith (Mere).—The paper is under consideration.

### "THE CAUSE OR CAUSES OF ACUTE TONSILLITIS."

*To the Editor of THE LANCET.*

SIR,—Personally my observations, so far as they go, bear out Dr. Atkinson's views. Three times I have had severe attacks, and twice mild ones, always either in May or June. On each occasion either a stress of work or some mental anxiety, coupled with an irregularity of diet, have preceded the attack. The same is true of a case which has occurred during the past week in my house. The patient is a Cambridge man, and has recently been in for examination, and in his case also considerable irregularity of diet preceded the attack.

I am, Sir, yours faithfully,

Warwick, July 24th, 1882.

KENNETH W. MILLICAN, B.A.

Mr. W. Davis.—We have no record of the receipt of the communication.

M.D. (Greenock).—The subject of our correspondent's letter is under consideration, and shall have attention next week.

### SEWER VENTILATION.

*To the Editor of THE LANCET.*

SIR,—Will some one of your engineering correspondents kindly give plan and action of "disconnected chamber" for ventilating sewers? Builders in country towns are ill-informed on the subject.

I am, Sir, yours obediently,

Hitchin, July 24th, 1882.

O. T.

**Martin.**—No licence is required for a single patient. On receipt of papers, notice must be sent to the commissioners. That is all. Two or more patients would require a licence, for which application must be made, in the first instance, to the Commissioners in Lunacy, at Whitehall, London.

**Mr. C. Roberts.**—As early as possible.

**CORRIGENDUM.**—In the second line of Mr. Hume's article on Ectropion, page 100, for "cornea" read *arm*.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. N. Cook, London; Mr. Chute, King William's-town; Dr. Buchanan, Glasgow; Mr. Larmuth, Manchester; Dr. Perkins, Exmouth; Mr. W. E. Bailey, Manchester; Dr. Roe, Patricroft; Mr. G. Abbot, Tunbridge Wells; Mr. J. Rorke, London; Mr. Scammell, Bristol; Mr. Clifford Allbutt, Leeds; Mr. Wilkinson, Rotherham; Dr. Sturges, London; Mr. Smith, Mere; Dr. Thomas, Glasgow; Mr. Millican, Kineton; Dr. Heywood Smith, London; Messrs. Evans, Sons, and Co.; Mr. Roe, Droitwich; Mr. W. J. Collins, London; Dr. Marcy; Mr. O. Foster; Mr. Carroll, London; Dr. Whelan, Loughrea; Dr. Bampton, Plymouth; Mr. Yelf; Mr. G. H. Thomas, London; Dr. Pearson, Maryport; Dr. Bennett, Liverpool; Mr. Wise; Dr. Warner, London; Mr. Duncan, Oldham; Mr. G. N. Stephens, London; Mr. W. Davis; Mr. Langton, London; Mr. Lediard, Carlisle; Mr. Waller, Rugby; Mr. Bailey, Crumpsall; Mr. Vincent Richards, Calcutta; Messrs. Thomas Pratt and Sons, London; Miss Stroad, Bristol; Mr. Codling, St. Albans; Mr. Bulmer, Hereford; Surgeon-Major Ellis, Wardha; Messrs. Thew and Son, King's Lynn; Mr. Gostrooke, Birmingham; Mr. Grayham, Pendlebury; Messrs. Pratt and Son, London; Mr. Trotman, Tunbridge Wells; Dr. Stanley Murray, Putney; Dr. J. B. Gill, Canterbury; Dr. Duke, Folkestone; Mr. Thomson, Dublin; Dr. Goodhart, London; Thesis; One of the Public; L.R.C.P.; H. A. D.; Student; X. Z.; Fairplay; Devonensis; Mac; &c., &c.

LETTERS, each with enclosure, are also acknowledged from—Mr. Scott, Manchester; Messrs. Porteous and Co., Glasgow; Messrs. Richards and Co., London; Mr. Johnson, Shrewsbury; Mr. Pullen, Budleigh, Salterton; Mr. Amplison, Ilchester; Mr. Scatchard, Woodhall Spa; Mrs. Moffat, Hawarden; Dr. Maskew, Lyndhurst; Messrs. Smith and Son, Dublin; Mr. Newey, Dudley; Dr. Rice, Claremont, U.S.A.; Messrs. Fannin and Co., Dublin; Mr. Piet, Baltimore; Messrs. Reid and Co., London; Dr. Scriven, Duffield; Mr. De Fraine, Aylesbury; Mr. King, Lancaster; Mr. Standart; Mr. Milne, Ladywell; Mr. Veale; Mr. Harrison, Liverpool; Mr. Sutherland, Burnockfield; Mr. Hyatt, Gosport; Mr. Hutcheon, Derby; Mr. Hallows, Newark; Dr. Hern, Darlington; Mr. Marriott, Nottingham; Mr. Brown, Westgate-on-Sea; Mr. Bennett, London; Mr. Shepperson, Brighton; Mr. Ewart, Selkirk; Mr. Jones, New Cross; Messrs. Rowe and Co., London; Dr. Shirliff, Kingston-on-Thames; Dr. Bager, Penicuik; Dr. Jones, Resolven; Mr. Jardine, Birmingham; Mr. Allinson, Kingsland; Mr. Williams, Pwllheli; Medicus, Exeter; M.D., Chalk Farm; Medicus, Liverpool; X.; Y.; Medicus, Lenty; Alpha, Caledonian-road; Delta; W. ## SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year.....£1 12 6 | Six Months .....£0 16 8  
TO CHINA AND INDIA ..... One Year, 1 16 10  
TO THE COLONIES AND UNITED STATES .. Ditto, 1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed. Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom, and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 87, Rue Caumartin, Paris.

## Address

ON THE

INFECTIVENESS OF TUBERCLE,  
WITH SPECIAL REFERENCE TO  
TUBERCULAR CONSUMPTION.*Delivered before the North of Scotland Medical  
Association, July, 1882,*

By WILLIAM PIRRIE, M.D., LL.D., F.R.S.E.,

PROFESSOR OF SURGERY IN THE UNIVERSITY OF ABERDEEN,  
CONSULTING SURGEON TO THE ROYAL INFIRMARY  
OF ABERDEEN.

GENTLEMEN,—I thank you most cordially for the honour you have done me in asking me to preside at this annual meeting of the North of Scotland Medical Association. I consider it not only an honour, but also a great pleasure, inasmuch as it gives me an opportunity of renewing my acquaintance with gentlemen with almost all of whom I have previously been placed in the pleasing relationship of teacher and pupil. As it is customary at these annual gatherings for the President to bring before the associated members some topic of medical or surgical interest, I have thought it would not be unprofitable to dwell for a few minutes on some of the researches in later times on the etiology of tuberculosis, as they tend to enlarge our conceptions of contagion; to correct many previously held doctrines regarding tubercle; to establish a substantial claim of contagiousness for that widespread and awfully fatal malady, consumption; to reveal to us its specific contagium or specific infecting medium; and to explain the facility with which it can be spread in a community. It has been said that one-seventh of all the deaths throughout the world and one-third of the deaths in active middle life are caused by tubercular disease. If this is correct, it must be all-important to be familiar with every addition to our knowledge of this important subject. The elaborate investigations carried on during the last few years regarding the etiology of infective diseases are of the highest interest to the practical surgeon and the sanitarian; but I intend on the present occasion to limit my remarks to the subject of the infectiveness of tubercle, perhaps the chief source of consumption, which is the commonest and most fatal manifestation of tubercular disease; and, as bearing on this important subject, to draw attention to the researches of recent experimental physiologists, ending with the remarkable discoveries of Koch, formerly of Breslau, and now chief of the Imperial Health Department of Berlin. Without going so far as Laennec did in his belief that phthisis is always tubercular, yet, if we grant that this widespread and fatal disease is in the main of tubercular origin, we cannot over-estimate the researches on the infectiveness of tubercle, which must greatly influence the therapeutics of those who believe in them.

It is not my purpose to consider whether the two processes now called by the separate names of the scrofulous and the tuberculous are really identical; nor to enumerate all the opinions promulgated on the pathology of phthisis; nor to review the facts advanced in support of the opinion that the little nodular growths, composed of giant-cells and a branched reticulum, and to which the name tubercle is now commonly limited, are always due to primary non-specific inflammatory action; but rather to trace recent experimental investigations with a view to showing how they prove that consumption is due to an infective process, and some of them to afford demonstrative proof of the morbid agent which so injures the pulmonary tissue as to lead to its subsequent consolidation and ulceration. They seem to justly claim for consumption the character of infectiveness arising from a special parasite. The contagiousness of consumption is not, however, promulgated for the first time in our own immediate day, nor even in the recent past, for in all ages, probably, some have held this belief. Thus Galen believed in its contagiousness, and ordered consumptive patients to inhale the vapours from the crater of Etna, whilst Morgagni, in his day, was of the same opinion. We read also that this

No. 3075.

belief has always prevailed in Italy, Spain, and other countries of Southern Europe. In our country and day many great men have denied this doctrine, whilst some have specially promulgated it. Thus, looking back on the more recent past, we find the late Dr. William Budd of Bristol, thirty years ago, as the result of clinical observation, expressing the opinion that pulmonary consumption was allied to the eruptive fevers, and differed from them only in its degree of virulence, and consequent rate of progress. He entertained no doubt in his own mind that it is of a highly contagious character; that its virulence in any country is in the inverse ratio of its duration there, being most rapid and fatal on its first introduction, and becoming, by long continuance, as in our own country, of a milder type and more chronic character. Thus we are told that when first introduced into the Sandwich Islands it sometimes proved fatal in less than six weeks; and we are all familiar with the fact that it often drags on, in our own country, a slow and at times intermitting course, extending over months or years. Still, these views of Budd obtained but few adherents, for the great bulk of physicians, dependent solely on clinical observation and practical experience, were decidedly of opinion that consumption could not be spoken of as a contagious disease in the same sense as the ordinary eruptive fevers are. Within later years, however, much has been done to give us more enlarged and precise views on the subject of contagion, and much that mere practical experience and clinical observation could not determine has been solved, and made matter of demonstrative proof by recent experimental investigations.

Now, if we assume, as already remarked, that consumption is, in the main, tubercular, its widespread diffusion is easily accounted for by the results of these researches and experiments, which, at the outset, proved that there was something in tubercle which possessed infective properties, and have culminated, in the hands of Koch, in making the special contagium, or the precise infecting organism, a matter of demonstrative proof.

About twenty years ago Buhl taught that acute tuberculosis was of an infective nature, and was owing to the existence of a primary inflammatory induration which had become caseously degenerated, and to the absorption of particles from the caseous mass. His view was that the infective substance was always associated with the secondary caseous change, but recent experiments on the artificial induction of tuberculosis in animals render this view untenable.

In 1865 Villemin commenced a series of experiments to prove that tubercle was an infective disease, and demonstrated the fact that caseation of the tuberculous matter was not necessary to constitute it a focus of infection. He took little bits of tuberculous matter, about a pin's head in size, from the body of a man, or a cow or rabbit, and inserted them under the skin of the ears, groins, or other parts of dogs and rabbits. The result was that the wound at first healed, but afterwards became red and swollen, and ultimately ulcerated, owing to the development of a tuberculous mass. If these animals were killed after fifteen days from the date of inoculation, a caseous mass, surrounded by small yellow granulations, was found at the seat of the wound; tubercles were found in the viscera, especially in the lungs; and, besides grey granulations, infiltrated masses of tubercle were discovered in varying conditions, according to the date of the animal's death. He found like changes to occur in instances where he injected hypodermically small quantities of the sputa of consumptive patients, mixed with water.

Chauveau of Lyons obtained like results from all his experiments, which were of three kinds. First, he gave some oxen, by the stomach, portions of tuberculous matter got in some instances from man, and in other cases from oxen, which are very prone as a class to what is known by the names of "pearl disease," "angle berries," or "grapes," from the peculiar condition of the serous membranes, or, generally, bovine tuberculosis; second, he inserted particles of tuberculous matter into the connective tissue; and, third, he injected into the veins water into which tuberculous matter had been placed and had been filtered. In all cases tubercle granulations were found in the lungs, and all the animals contracted tuberculosis.

We may here conveniently mention that Dr. Charles Creighton, in his interesting work on bovine tuberculosis in man, published last year, describes numerous cases in which a condition of organs in the human subject was found similar to that seen in oxen dead of tuberculosis; and he establishes

the extreme probability that the disease is not unfrequently transmitted to human beings through eating the flesh or drinking the milk of diseased cows. Professor Gerlach also states that healthy oxen can be infected through the milk of sickly cows, or by taking with their food portions of tuberculous matter from the organs of affected animals.

These investigations proved that tuberculosis could be produced in suitable animals by the introduction, in various ways, into their systems of true tuberculous matter; but some years ago Dr. Burdon Sanderson and Dr. Wilson Fox performed various experiments on rabbits and guinea-pigs, which they believed to prove that tuberculosis could be produced in these animals by inoculating them with any of the products of ordinary inflammatory action, or even by such substances as fatty liver or putrid muscle—nay, even by the production of local injuries, such as a deep wound, or the insertion of a seton. For a time many concurred in these opinions, and viewed the bodies found after the experiments of Villemin, Chauveau, and others as mere inflammatory products, or infarctions, and not true tubercles at all; but the tendency of more recent experiments is to cast doubt on the assertion that any irritating foreign body could induce tuberculosis in these animals, and to confirm the belief that true tuberculous matter alone can produce general tuberculosis, and that the products of inoculation with non-tuberculous matter are not true tubercle, but what Dr. Hippolyte Martin of Paris calls false or "pseudo-tubercle." His experiments are so remarkable, and his statements so decided, that we must refer to them; but in doing so we may as well premise that he holds that true tubercle is an infective malady originating in a specific though undetermined virus, and that its propagation arises solely from the conveyance of this virus from body to body. By this one peculiarity, he maintains, is it possible to determine true infective tubercle from the false or non-infective. True tubercle produces general tuberculosis from a local infection, the virus increasing with successive inoculations; whereas non-tuberculous matter after inoculation produces a local tubercle, but inoculation from this secondary tubercle is quite powerless to produce general tuberculosis. He says it is always indispensable to conduct experiments on this matter with the most rigorous regard to antiseptic precautions, lest particles of real tubercle be accidentally injected, and this is the more important because, according to him, it is impossible to distinguish under the microscope, so far as anatomical characters go, between true and false tubercle—the one only distinguishing feature being the infectiveness of true tubercle. In this he is supported by Professor Cohnheim, who, though I am not able to quote his exact words, had previously given his opinion to the effect that under the head of tuberculosis should be ranked all that after its inoculation on suitable animals produces tubercle, whilst all that fails to do this is not tuberculous; and that the anatomical definition of tubercle is useless and must give place to the etiological.

Dr. Martin conducted two sets of experiments to prove the infectiveness of tubercle. With the greatest antiseptic precautions, he injected into the peritoneal cavity of guinea-pigs irritating substances of vegetable and animal nature, such as pepper, cantharides, fragments of sarcoma, particles from a carcinomatous mamma, particles from the caseation of a sarcomatous tumour, and other non-tubercular matters, with the results that in most instances the animals remained quite healthy, and when killed had no disease of the viscera. In other cases he showed that foreign bodies could set up ordinary inflammatory action, the products of which could not be anatomically distinguished by the microscope from the true tubercle, which always followed inoculation with true tuberculous matter. These secondary tubercles, after inoculation with tuberculous matter, had the distinguishing characteristic of increasing infectiveness from successive inoculations. Hence he concludes tubercle is an infective malady, owing to the presence of some morbid agent, peculiar to it, but undetermined. This agent Koch seems to have discovered in the form of a minute organism, which now goes by the name of the bacillus of tubercle. We may, however, previously enumerate experiments which, while proving that tubercle is infective, also demonstrate some additional ways in which the parasite may find an entrance into the bodies of unaffected persons.

Tappeiner, Bertheau, Weichselbaum of Vienna, and other investigators, caused dogs and some other animals to breathe an atmosphere in which the sputa of consumptive patients, and other forms of tuberculous matter, were diffused in the

form of spray; whilst they made others respire air through which they diffused atomised liquids impregnated with non-tuberculous substances. The results of these experiments were as follows. In all cases where real tuberculous matter was used, tubercles were found in the lungs, kidneys, and other organs, but especially in the lungs, the abundance of the tubercle being generally proportionate to the length of the experiments and the frequency of the inhalations. In those cases again where non-tuberculous matter was sprayed into the air, either no tubercles were found, or only a very few nodules, and these, perhaps, of doubtful character.

Again, in France, M. Giboux operated on rabbits directly with the air itself expired by consumptive patients, with a view to determine whether it could induce tuberculosis in healthy animals. Into one room he placed a cage containing two healthy rabbits, and into it he passed daily, for some time, twenty or twenty-five litres of air expired by phthisical patients. Into another separated room he placed a second cage also containing two healthy rabbits, and into it he passed daily a similar amount of air expired by consumptives, but previously filtered through tow charged with carbolic acid. The consequences were, that at the end of about three months, the rabbits in the first-named cage became emaciated and showed signs of disease, and at death tubercles were found in all the organs, but especially in the lungs; whereas, in the second pair of rabbits, there seemed to be no injury to health at the end of a like period, and their organs, when the animals were killed, were found free of tubercles.

All these various modes of artificially producing tuberculosis in suitable experiment-animals—some by inoculating tuberculous matter beneath the skin, some by giving it by the stomach, some by injecting it into the veins, others by giving it through inhaling an atmosphere impregnated with tuberculously tainted spray, and others by directly administering the breath of consumptive patients—point to the conclusion that there must be some special infecting virus in real tubercular matter. About five years ago Professor Klebs stated that the contagiousness of tubercle was owing to a microphyte, and his discovery regarding tubercle was proved, by Dr. Schräller of Greifswald, to hold good regarding certain affections termed scrofulous; as, for example, scrofulous affections of glands and scrofulous disease of joints, in all of which he said the same microphyte was found.

We will, however, in closing, refer at greater length to the experiments of Koch of Berlin, as they are the latest, the most striking, and, perhaps, the most decisive. Koch had previously acquired an extended and great reputation by his exhaustive researches into the contagium of splenic fever. His great aim was to discover what the precise character of the contagium was which rendered tubercular disease communicable from one individual to another, and capable of indefinite reproduction. The result of his experiments was, that in all true tubercles found in cases of general tuberculosis, a special micro-organism was discovered. It may be fittingly asked, Do these micro-organisms or parasites occur in any numbers, do they in any degree infect the tissues of a healthy living body, or do they occur only in special states of disease? Koch and others are decidedly of opinion that they do not occur in the tissues of healthy living bodies, and they have also proved that, though different parasites live and flourish under somewhat varying temperatures and attendant circumstances, yet they all agree in this, that, when once introduced into the living body, their life and increase are greatly favoured by a low state of the general health. According to Koch, the tubercle bacilli are found within the giant-cells, and they are delicate rod-shaped bodies varying in length from one-quarter to one-half the diameter of a blood-corpuscle. We are further told that these bodies are most numerous in recent and advancing tubercle, and that they become fewer in proportion as the tubercle gets older, and finally disappear on the healing up of the tubercular disease. Dr. Koch also tested the expectoration of many who were suffering from consumption, and invariably found in it multitudes of bacilli, while he could discover none in the sputa of non-consumptive patients. He also found that the bacillus of tubercle required, in inhabitants of the temperate zone, about the warmth of the animal body for its growth and increase; and, in this respect, it differs from the bacillus of other diseases, for we are told that the bacillus anthracis found in cases of splenic fever can live in a temperature much lower than that of the body—outside the body in fact. Having discovered the parasite, the next point which Koch set himself to decide

was whether or not it was the real and only cause of infection; or whether some of the matters by which it was surrounded were so. To determine this point it was needful to differentiate the bacilli from the tissues in which they lay; and this he succeeded in effecting by means of a special dye. To make sure that it was the parasite alone that was the medium of infection, and not any surrounding virus, he cultivated the bacilli artificially through many successive generations. With a speck of tuberculous matter from a human lung, he infected different substances, carefully prepared, so as to afford nutriment to the parasite. From these he infected fresh nutritive material, and so on, till many broods of the parasite were obtained. After the bacilli had been several times transferred from one soil to another, the original tubercular matter was at length got rid of, and nothing but the bacilli was left behind. Now, inoculation with these bacilli, isolated from all the original surrounding matter, was followed by reproduction of the parasite, and by the induction of tuberculosis, as certainly as was inoculation with a speck of tuberculous matter containing living bacilli. The same results followed when the bacilli were placed in fluids contained in porous clay vessels—inoculation with the fluid which was sweated through the clay was innocuous, whilst inoculation with the bacilli was followed by their reproduction, and by tuberculosis.

We have thus traced a belief in the contagiousness of consumption held by a few probably in all ages, springing from observation and practical experience; and we have seen how it is justified by the results of experimental research in our own days, and that at last, within the past few months, the precise infecting parasite has been made a subject of microscopic demonstration.

Now, if Koch's statement, already mentioned, that one-seventh of the human race die of tubercular disease, and that this disease causes fully one-third of the deaths occurring in active middle life, be true, it is impossible to overstate the importance of his discoveries regarding the nature of the bacilli found in tubercle, and in the expectoration of consumptive patients, which he says does not lose its virulence though reduced to a state of perfect dryness. The question now arises, If consumption is an infective disease, can anything be done to destroy its virulence, or to arrest its ravages to a degree hitherto unattained? This much we may safely assert, that the results of all the experiments we have detailed clearly indicate the need of recognising the parasitic origin of tubercle, of fortifying the body against the invasion, and against all circumstances favourable to the development, of the bacilli, as well as of aiming at the destruction of those already pervading the infected organs. With this in view, we must remember the importance of attending carefully to the improvement of the general health of all consumptives, to the avoidance of close confinement in over-heated and overcrowded rooms, to the keeping the patient as much as possible in the open air in suitable weather, to the careful ventilation of sleeping apartments and sitting-rooms, whilst guarding against preventable draughts, to the separation of the healthy from the sick as far as possible at night, and to warning the healthy against all avoidable inhalation of the breath of consumptive patients, who, in their turn, must be kept from rebreathing their own breath. Serious attention should be bestowed also on the disinfection of the sputa of consumptive persons; and much good may be expected also from the more assiduous use of antiseptic inhalations than has been practised in the past.

Perhaps, in all that has been said we may find a plea for cottage hospitals in open suburban parts, in place of general or large special hospitals for consumptives; and one without doubt for a more careful supervision of the health of cows, whose milk is an article of daily use by the consumptive, and enters so largely into the dietary of all non-consumptives, especially into that of children; as we are told the milk of animals suffering from tubercular disease is capable of transmitting it to previously healthy human beings.

At the last meeting for the present session of the Court of Common Council of the City of London, the Right Hon. the Lord Mayor in the chair, it was resolved, on the recommendation of the Finance Committee, to distribute two hundred and fifty guineas as follows:—£105 to the British Home for Incurables, £105 to Miss Mary Hardell's Scarlet Fever Convalescent Home, and £52 10s. to the Tower Hamlets Dispensary.

## Arris and Gale Lectures ON THE RELATION OF EXPERIMENTAL PHYSIOLOGY TO PRACTICAL MEDICINE.

*Delivered at the Royal College of Surgeons, June, 1882,*

By G. F. YEO, F.R.C.S.,  
PROFESSOR OF PHYSIOLOGY IN KING'S COLLEGE.

### LECTURE III.—PART II.

#### THE DEPENDENCE OF THE MODERN RATIONAL METHODS OF TREATMENT UPON A KNOWLEDGE OF PHYSIOLOGY.

I HAVE pointed out that it is rather by shedding a general light on the normal functions of the various organs of the body, than by formulating special modes of treatment, that physiological research will advance medical knowledge. Specific examples of immediate benefit to practice are, however, more striking to lay people than the clearest evidence of the effect of general advance. I shall therefore refer to some instances in which these advantages appear in a more concrete form.

Until within the present century it was the practice of surgeons to cut down on and divide the portio dura of the seventh pair of nerves, at its exit from the parotid gland, in order to cure neuralgia of the face. This operation caused loss of motion of one side of the face, without in the least influencing the pain, for this nerve has nothing to do with the transmission of sensory impulses. This useless proceeding was even continued for some time after Sir Charles Bell had shown the real function of this nerve.

This same nerve is often more or less completely deprived of its function by pathological processes of different kinds. The result is the well-known facial paralysis. Its various causes may affect different parts of the nerve,—within the cranium; in the petrous part of the temporal bone, or in the more superficial portion on the side of the face. In each of these situations the prognosis and the treatment should be different, and their differential diagnosis is therefore essential before a rational treatment can be determined. The key to this difficulty lies in what we have learned from vivisection, combined with an exact knowledge of anatomy. There are certain branches that spring from different parts of the nerve whose functions are known to us only as the result of vivisections—e.g., the chorda tympani nerve, which bears secretory impulses from the brain to the submaxillary gland, and the lesser superficial petrosal branch, which carries taste-impulses from the tip of the tongue to the sensorium; these come off from the nerve in its passage through the temporal bone. If, then, a bitter substance applied to the tip of the tongue on the affected side fail to produce a bitter taste, and if weak acetic acid do not produce a flow of saliva from the gland on the affected side, the lesion must implicate the origin of these branchlets, and therefore be deeply seated.

Again, it is to vivisection that we owe the introduction and the perfection of the operation of transfusion as a mode of treatment. By experiments on dogs Lower first demonstrated and made well known to the scientific public, in the seventeenth century, the possibility of replenishing the blood of one animal by that taken from another. I am aware that the claim of priority concerning the operation of transfusion is disputed. Dr. Ogle, in his Harveian Oration, has distinctly shown that the story of the transfusion of the blood of the three boys into the vessels of Pope Innocent VIII. is not to be accepted, the repeated mention of it being merely from hearsay. A description of how the operation might be performed is given by Libavius, the chemist of Halle, but he severely condemns its practice. But whether Libavius did it himself or not, and the former supposition seems very questionable, there can be no doubt that it had been often carried out on the lower animals before it was attempted on man. In more recent times many improvements have been made in the operation by vivisections. For instance, it has been shown that freshly defibrinated blood is as efficacious and as safe as that from which the fibrin has not been removed. Moreover, the danger of using

the blood of dissimilar animals was shown, and surgeons were thus warned against a mode of practice that at one time had proved a great drawback in the adoption of the operation, for it made the result very uncertain. Thus we see that whoever first actually performed the operation, it was by experiment on the lower animals that a method of saving life in cases of severe hæmorrhage was placed in the hands of the surgeon, and by the same means its application has been robbed of its chief dangers, so that by it a large number of human beings have been rescued from bleeding to death. But this wonderful means of saving life is not applicable to cases of dangerous bleeding only. In charcoal suffocation we know—chiefly by experiment—that of the noxious gases evolved by the burning charcoal, one, carbon monoxide (CO), acts differently from the other, carbon dioxide (CO<sub>2</sub>). In the former case the gas forms a stable compound with the colouring matter of the blood, not only replacing the oxygen which the hæmoglobin normally carries, but also preventing the future union of that gas with the blood corpuscles. The blood in which the hæmoglobin is combined with carbonic monoxide is of a brilliant scarlet colour, unlike that of carbonic acid poisoning, or of ordinary suffocation, in which case it is dark. In pure carbonic acid poisoning artificial respiration is most useful, and, as a rule, will suffice to restore the reduced hæmoglobin to its natural oxygenated state. In poisoning with carbonic oxide, on the other hand, experiment has taught us that artificial respiration is useless, and that the permanently spoiled hæmoglobin must be got rid of by bleeding, and fresh blood supplied in its place by transfusion. In calculating the value of transfusion it must be remembered that it really is a means of saving life rather than a mode of treatment, for it is only employed as a last resource in otherwise hopeless cases. In fact it brings back to life one practically dead. Yet I find that more than half of the recorded cases in which it has been used have been successful, and the dying patients have been saved from a sudden and certain death. The following table gives the result of 216 cases:—

	No. of cases treated.	No. cured.	Per. cent. cured.
Post-partum hæmorrhage.....	108	63	58
General hæmorrhage.....	75	38	50
Intestinal hæmorrhage.....	18	10	55
Carbonic oxide poisoning....	15	6	40

I shall not enumerate the many operations—otherwise impossible—which the use of aseptic surgery has enabled the surgeon to perform, although we may in a great measure claim antiseptic remedies as the direct outcome of experiment on living animals. There are, however, several surgical operations which owe their origin or application so directly to experiments on the lower animals, that they must be alluded to, however briefly. The operation for amputation through the hip-joint was performed on dogs, and on its success being reported to the French Academy, it was generally applied in military surgery to the human subject. Of its feasibility as an operation there is now no doubt. The improvements in orthopædic surgery which, though recent, are now regarded as a matter of course, chiefly depend on the physiological investigations which Stromeyer, v. Ammon, Bouvier, Guérin and others carried on in this century. Tenotomy was hazardous and unsatisfactory in the extreme until the subcutaneous method was perfected, and the mode of repair of tendons fully investigated upon the lower animals by the authors just named and many others. So much has already been said about Hunter's experiments in relation to the operation for aneurism, that I shall content myself by reminding you that they have a direct bearing on many methods used in modern surgery in general, and that they were not merely useful in leading to one mode of curing aneurism; and further, that, no matter who first tied the artery above an aneurism to accomplish its cure, such a proceeding was only made justifiable by the knowledge of the circulation which was acquired by vivisection.

There are many operations which have been performed on the stomach and the other abdominal viscera which are the outcome of vivisection. So long as thirty years ago Sédillot was tempted by the facility with which Blondlot established gastric fistulæ in dogs, for the purpose of making experiments on digestion, to perform a similar operation on a human being. Having under his care a case of cancer of the œsophagus, in which life was threatened from inanition, he determined to open the stomach. He did so according to the rules of experimental physiology, and pos-

sibly prolonged the patient's life, and certainly improved his condition while he lived. Since then Billroth has removed a portion of the stomach for cancer. And Czerny of Heidelberg has removed a cancerous tumour involving the pylorus of a man who seemed to be rapidly sinking from the occlusion of the outlet of the stomach and constant vomiting. In a little more than a month after the operation the man increased nearly a stone in weight, and then returned to his work. More striking still is the case of a healthy young girl, who by accident swallowed some corrosive poison, and recovered from its immediate effects. The œsophagus was so much injured that swallowing was out of the question, and even the introduction of food through a tube was attended with great difficulty. The awful death of slow starvation was the only prospect before this otherwise robust girl. She was operated on in exactly the same way as experience had shown was the safest to establish a gastric fistula in a dog. She now feeds herself, and enjoys life. Here, then, is a simple answer to the statement that "not one benefit has accrued from the labours of the physiologist, either to medical or surgical science?"

Wounds of the intestine have always been regarded with great dread by surgeons. By an experiment on a dog it was shown that by securing the union of the serous surfaces a portion of the intestine could be removed, and the ends of the remaining portion sewn together so that the peritoneal surfaces united. Since the original experiment of Shipton, a young Englishman, similar operations have been frequently performed on animals for the purpose of collecting the intestinal fluids. Upon the same principle wounds of the human intestines have frequently been caused to unite, and, as Mr. Benjamin Travers has shown, by this means much of the horror formerly attached to strangulated hernia has been dispelled.

There is further a surgical instrument which, in special cases, is of great value, the invention and applicability of which was aided by experiments on lower animals. M. Chassaignac was led to imagine on *a priori* grounds learned from surgery, that a torn tissue would not bleed as it would when cut with the knife; but humanity forbade his at once applying his theory to human beings; so he first used the écorseur upon dogs. He says, in describing experiments made on the tongue of these animals: "When the crushing was conducted slowly, the solution of continuity was dry; there was no hæmorrhage, either primary or secondary." I have seen M. Chassaignac in his hospital practice sit with most exemplary patience slowly applying the rules he had thus learned from vivisection to the removal of tumours which the knife could not have reached.

In many cases where disease of a bone or joint used in former days to demand the removal of the limb, the bone or the joint now only is removed, and the rest of the extremity—a sound hand or foot probably—is left to the patient. This change in practice was in a great measure brought about by the knowledge of a fact which was derived from experiments on living animals. In the last century Duhamel clearly proved the mode of growth of bone, and placed beyond a doubt the fact that the periosteum can produce bone; and Michael Troja showed by experiment the more accurate details of the process long before subperiosteal operations were thought of for the alleviation of human suffering. Nearly fifty years ago, Mr. Syme made experiments on animals on the subject of the formation of bone from periosteum, and showed the immediate application of his results to surgical practice. In 1867, M. Ollier of Lyons made a more elaborate work on the subject, which brought the matter prominently forward. Probably there is no point which has contributed more to the advance of "conservative surgery" than this. Whether an elbow be flexible or rigid after its excision, or whether a limb be too short or distorted after the subperiosteal resection of the bone, it is an inestimable gain to retain a living and moving hand instead of a stump-hook.

The fact that a dog can live in the enjoyment of perfect health after one kidney has been removed has often been established in physiological laboratories. This operation has now frequently been performed on the human subject, and repeatedly with success in cases where all other means of prolonging life or making it bearable had failed.

A case occurring in his clinique, in which malignant disease of the larynx threatened a man with immediate and sudden death, Billroth conceived the idea of removing the entire organ. One could hardly do such a terrible operation, even on a dying human being, without some kind of

experience to instruct and guide one. Accordingly, Czerny, who was then his assistant, did the operation successfully on a number of dogs, and thereby gained such knowledge as to enable Billroth to carry out his intention. He operated and the patient recovered, and with an artificial larynx could breathe and even speak in a whisper.

The whole history of our knowledge of inflammation is so interwoven with experiments on living animals that I could not attempt in the short space of an hour to trace out the many and great obligations that pathologists owe to vivisection for elucidating the minute changes in this process. I need only refer to the experiments of Hunter, Thomson, Wharton Jones, Paget, Virchow, Lister, Cohnheim, Stricker, and others, who have made this important topic a special subject of study. Nor will time allow me more than to name the application of experiment on the lower animals to the infectious diseases and the febrile state in general. The results of Koch's work on the infection from wounds and splenic fever, and Pasteur's beautiful researches, not only form strong rocks of defence against the clamorous ignorance of those who prefer mystic to common sense and sentiment to rational modes of treatment, but they also afford great encouragement for the future of experimental research by showing what results may thus be attained.

With regard to remedies suggested, or discovered by vivisection, it must be remembered that experimental therapeutics as a science is in its infancy, and therefore their number is not great. There are, however, some very important drugs which owe their introduction into medicine to experiment on the lower animals. Much has been written and said about the few remarkable cases in which drugs have a different effect on some animals from that which they exercise on man. It must be remembered that these are rare exceptions, and only occur in the case of a few animals, so that by using animals of different species the probable effect of any medicament on man may be determined with sufficient certainty for its efficacy on the human subject to be tried with impunity. It is generally the experimenter himself upon whom this trial is first made. Among the drugs which we certainly owe to experiment on living animals—such experiment as would come under the Act though not really vivisection—is chloral hydrate. From the chemical composition of the substance Liebreich thought that it would have much the same effect as chloroform, and he found by trying it on rabbits and other animals that such was the case. It induces sleep, and in larger doses destroys sensibility. In large doses it affects the heart and lowers the animal heat so as to become dangerous. When used to prevent pain in operations on the lower animals care must be taken to keep the temperature from falling, and this should be remembered in treating cases of poisoning by this drug. We knew from vivisection that the alkaloid of deadly nightshade, atropin, checks the secretion of saliva. Often in cases of paralysis, and sometimes in fracture of the skull, dribbling from the mouth is a most distressing symptom; it saturates the pillow and robs the poor patient of much needed rest. A little atropin injected under the skin in the neighbourhood of the gland checks for hours the flow of saliva, and enables the sufferer to enjoy a quiet sleep. But belladonna is a dangerous poison, acting, as vivisection shows, by depressing the heart-nerves; but it has also been demonstrated that a substance which can be extracted from a bean used in Calabar as an ordeal poison, has an antagonistic influence on the nerves of the heart, and acts as an antidote in cases of belladonna poisoning.

We know further from vivisections that a substance called amyl nitrite causes general relaxation of the bloodvessels. It has therefore been used with success in cases of headache arising from spasm of the cerebral vessels, and has been found of more value in that agonising disease called angina pectoris than any other known remedy. The alkaloid of nuxvomica, strychnia, was also introduced into practice by experiments on the lower animals, and its remarkably stimulating effects on the spinal cord were made out by Magendie. It is now in common use, and is recognised as a valuable nerve tonic. Strychnia is known to be a terrible poison, but the alkaloid of tobacco, nicotine, has been put forward as its antidote by Professor Haughton, from the experiments which he performed on living animals. For a very long time the occurrence of sugar in the urine has been recognised as the chief symptom of diabetes. The mechanism of its production and the locality where the sugar was

formed, were alike unknown until Claude Bernard determined the glycogenic function of the liver. We now know that any disturbance of the vaso-motor mechanisms of that great gland causes an excess of sugar to appear in the blood and be eliminated by the kidneys. This is at least a step towards the pathology of this disease. By vivisections we know further that the production of sugar depends upon the presence of a ferment which changes the normal glycogen into grape sugar. Is there nothing that will check this process and save the economy the great loss of sugar? From experiments by Lemaire we learn that carbolic acid checks fermentative changes. Relying on this and other information acquired by vivisection, carbolic acid has been tried internally in some cases of diabetes, and in a certain number of these cases the sugar has disappeared from the urine.

Although I have enumerated these special instances in which vivisection has directly benefited practical medicine and surgery, I do not wish to lay stress upon them as the strongest evidence in favour of the necessity of experimental research. I must once more insist that the immediate object of physiology is not to invent cures for disease, but to learn the normal operations of the living economy. If we could remove from our thoughts of a case of disease the memory of even one of the great facts which form the basis of our physiological knowledge, which have been derived from vivisection, and if then we attempted to arrive at the diagnosis, prognosis, and treatment of the case in question, we should find that the entire fabric upon which we base our arguments would collapse like a house of cards from which one card from beneath has been roughly withdrawn. In his evidence before the Royal Commission the venerable Professor Wm. Sharpey said: "I think that vivisection is of value as promoting the science of physiology, and that again is one of the great foundations of all rational medicine.....It puts a lamp, so to speak, in the hand of the physician when he is studying disease.....In short, I should say that physiology is not to be compared to a reaping machine, but rather to the plough."

Rational therapeutics must grow out of physiological knowledge, as surely as a plant is the outgrowth of its roots. As the remote rootlets are the exact parts which are all-important for the nutrition of the plant, so experiment feeds physiology and thereby nourishes the art of medical practice. It would appear silly to ask to what rootlet any single fruit or flower on a widely-spreading tree owed its existence or nutrition, and so it is idle to expect that each, or even any, therapeutic agent or method of diagnosis should be traced to the definite experimental discoveries that may have led to its adoption or use. As the branches of our medical tree spread wider and wider and its diagnostic flowers and therapeutic fruits become more and more numerous, we find that its physiological roots go deeper and deeper in search of pabulum, and the experimental rootlets become still further removed from the more obviously useful and prolific part of the plant.

## ON THE ABORTIVE TREATMENT OF GONORRHOEA.

By W. WATSON CHEYNE, M.B., F.R.C.S.,  
ASSISTANT-SURGEON TO KING'S COLLEGE HOSPITAL, AND DEMONSTRATOR  
OF SURGERY IN KING'S COLLEGE.

GONORRHOEA, though not generally regarded as a formidable disease, is in reality from its frequent complications and after consequences a very serious affection. A glance at the more important of these complications and after consequences will illustrate the truth of this statement, for among them we have phimosis, paraphimosis, inflammation of the cellular tissue of the penis and scrotum with abscess formation, or even in rare cases strangling and possibly perineal fistula, proctitis, cystitis, nephritis, even peritonitis, orchitis and sterility, bubo, conjunctivitis, scleritis, synovitis, and as more remote consequences we may have stricture of the urethra with all its dangers and complications. The full appreciation of these facts leads to the conclusion that gonorrhoea is by no means a trivial complaint, indeed the consideration of them led the late Professor Bumstead to say that gonorrhoea kills more patients

than does syphilis. The very serious character of the disease and the frequency of complications have induced surgeons to make attempts to cut the malady short in its early stages by what have been termed abortive methods.

The usual methods of treatment I need not discuss. They consist in the use of various means to moderate the intensity of the inflammation and to shorten the duration of the inflammatory stage. The chief of these is rest by keeping the patient in bed; the removal of all causes of excitement, as alcoholic drinks, &c.; and free purgation. Rest is given to the part as far as possible by diminishing the irritating state of the urine by the administration of alkalies to render it neutral or slightly alkaline, by the use of diuretics and plenty of mucilaginous drinks, &c., to dilute it, and so on. No local astringent injections are employed till the acute inflammatory stage has subsided; but copaiba may be given before it has quite passed off. When the scalding and other symptoms of acute inflammation have disappeared, injections of various kinds are used. With regard to the length of time required for the treatment of a patient in this way, it may be instructive to quote what Bumstead and Taylor say: "The reader may be interested to know what is the average duration of treatment required in the hands of the best surgeons for the cure of gonorrhoea, laying aside those cases which are seen in the first stage (i.e., before acute inflammatory symptoms have set in), and which are speedily cured by the abortive method. This may be estimated at four to six weeks. Greater success, on the average, is probably not attainable by any means with which we are at present acquainted." The edition from which I quote is the last, and was published in 1879.

The first method employed with the view of cutting short the disease, and, indeed, the only one, as a rule, mentioned in text-books, is the injection of a strong solution of nitrate of silver into the urethra. This was introduced by Debeney, and has since been variously modified, but is now rarely used. Debeney started on the nowadays untenable theory, though one still to be found in some text-books of surgery, of trying to substitute a healthy inflammation for an unhealthy, and then curing the healthy. Debeney's method was to inject into the urethra a solution of nitrate of silver of the strength of sixty-four grains to the ounce of distilled water; and he used his injection in any stage of the disease. The results were generally disastrous. Cullerier says of it: "As soon as the caustic liquid has touched the urethral walls, a horrible pain is experienced, so great as to make the patient cry out, and often to induce syncope; then a very rapid and enormous swelling of the penis occurs, often with profuse hæmorrhage." As a rule, a cast of the patient's urethra comes out in a few days, and, where the effects subside without such complications as abscesses, diffuse inflammations, or the patient's death, the gonorrhoea is rapidly cured. Since the time of Debeney, and of his follower and advocate, Gueterbock, the attempts at abortive treatment have been confined to the stage prior to the appearance of the acute inflammatory symptoms—that stage where the patient first notices a little irritation, or a slight mucous discharge at the orifice of his urethra, and the strength of the injections has been much diminished. Ricord used for a time an injection of sixteen grains of nitrate of silver to the ounce of water; but this also was found to be much too irritating, and was frequently followed by complications, and he therefore abandoned it. Of late those who have employed the abortive method have reduced the strength of the solution, till now it is only one grain of nitrate of silver to the ounce of water. All authors concur in condemning these attempts, unless they are practised before there is any pain in passing water or any well-marked inflammatory symptoms. This is a condition in which patients are seldom seen, and therefore the method has practically fallen into disuse. This method was modified by Johnson, who advocated the reiterated use of weak injections. He says, writing in 1851: "Perhaps the precise kind of injection is not of so much moment as its dilute character, its early employment, and its frequent repetition." He mentions a variety of solutions of the strength of half a grain of the salt to an ounce of water; some, indeed, as nitrate of silver, so dilute as one grain to six ounces of water. At the same time he administered copaiba. The result was very various. In some cases cure was effected in a few days; in others in two or three weeks; in others the inflammation ran its usual course. Johnson, however, only got the favourable results when the patient commenced the treatment a few hours after the beginning

of the gonorrhoea. If the inflammatory stage had once set in but little benefit was derived.

Another method was advocated by Cullerier. It consisted in the employment of large doses of balams, more especially of copaiba, and also large doses of cubeba. He gave six to eight drachms of cubeba and four to six drachms of copaiba in the day. This is used in cases of gonorrhoea seen within eight days after infection; but once the inflammatory symptoms have reached any height he does not advise the method. As he says, in some cases a rapid cure is effected, but there is a great tendency to disorder of the digestive organs, and sometimes inflammation of the urinary organs may supervene. This method is quite unsatisfactory, and has not taken any hold on the profession.

Niemeyer tried to check gonorrhoea by another plan. He did not inject irritants but astringents, with the idea of constricting the vessels and thus rendering the inflammation impossible. He used tannin dissolved in red wine. He says: "I usually order three powders, each of which contains half a drachm of tannin. One of these is dissolved in half a pint of red wine, and the solution used as an injection. If the result is unsatisfactory the other two powders are to be put into the same quantity of wine, and the injection to be continued with this doubly strong solution." This method, like the others, is only of use in the very early stage; but he says that, when employed in time, he has cut short a large number of recent virulent gonorrhoeas in two or three days. He also adds, "Even where the disease is not quite recent, but where the inflammation is not very violent, I have often used the tannin, and obtained excellent results although the cure was less rapid." I have only tried this method in one case seen a few hours after its commencement, and the result was fairly satisfactory. Inflammatory symptoms never appeared, but a little discharge remained for about three weeks. This method, which I believe to be the best, has, however, the same disadvantages as the others—viz., to be successful treatment must be begun very early, at a period, indeed, at which the surgeon seldom sees the patient. And where it is successful one cannot always be certain that the inflammatory symptoms would have become more marked had it not been employed—i.e., one cannot tell that the case was one of true virulent gonorrhoea.

In the *British Medical Journal* for July 24th, 1880, I published an account of a new method which I had introduced for the purpose of arresting gonorrhoea, and it is with the view of giving the results of my attempts to cut short the gonorrhoeal inflammation that I publish the present paper. The principle on which I started was, to quote from my former paper, that "the extreme contagiousness of this disease, the existence of a distinct period of incubation, and the steady spread of the inflammation, all point strongly to a parasitic origin." I had found micro-organisms of a particular kind always present in gonorrhoeal pus, and they have also been described by other writers, and, reasoning from analogy, I concluded that gonorrhoea was probably due to the growth of an organism in the mucous membrane of the urethra, giving rise to a more or less acute inflammation of its mucous membrane. I will not discuss here the accuracy of my views, for I hope shortly, in conjunction with Mr. Jennings Milles, to publish an account of some investigations which we have been making on the subject.

Granting, however, that these views are incorrect, and that gonorrhoea is due to the continuous growth and spread of something introduced from without, possibly belonging to the group of schizomycetes, it is evident that the destruction of these bodies, or the arrest of their growth, ought to stop the progress of the symptoms, supposing that the agent employed for this purpose is of itself innocuous. This is what I have tried to do, and what, probably, happens in the other methods of abortive treatment when they are successful; for the injections of nitrate of silver and Niemeyer's tannin and alcohol solution are to some extent destructive of plant life: while Johnson's method of frequent irrigation of the urethra washes away the products of growth of these organisms, and possibly many of the organisms themselves. As I pointed out in my former paper, the organisms probably require for their easy spread that the mucous membrane be diminished in vitality. This they do by the products of their growth, which irritate and cause inflammation of the mucous membrane; and when the resisting power of the tissue has been in this way diminished, they grow in it with ease. Now, if these products are constantly washed away, this weakening of the tissue is not so great, and the growth of the organisms

in it occurs only with difficulty. If, however, the organisms have got a good hold of the tissue, very little benefit can be derived; and experience has shown that the method is of little use when the acute symptoms have advanced before it is begun. The mode in which large doses of copaiba act is less evident. We know from Ricord that it does not produce its effect through the blood, but that it is excreted by the kidneys in some altered form, and that it is the urine containing this product of the introduction of copaiba into the system which, passing over the mucous membrane in the urine, brings about the good result. It may be either that it is a parasiticide, or that it has some special effect in arresting the inflammation. I have not yet tested the parasiticide properties of such urine; but in one case, where I kept it for several days, it certainly did not decompose so soon as would have probably been the case had copaiba not been previously administered.

The materials which I employed with the view of destroying the cause of gonorrhœa were chiefly iodoform and eucalyptus oil, and these I still use. As injections are apt not to penetrate sufficiently far, and as their effect is only momentary, I combined these substances with cocoa butter, and made them up in the form of solid rods about 4 in. or 5 in. in length, and about the thickness of a No. 10 catheter. These rods weigh forty grains each, and each contains five grains of iodoform and ten minims of eucalyptus oil. They are dipped into eucalyptus oil, introduced into the urethra, over the orifice of which a pad of boracic lint is applied, and outside this a large piece of gutta-percha tissue, the whole being fastened on by strapping, and retained for four or five hours if possible. The cocoa butter soon melts, and a solution of iodoform in eucalyptus oil bathes the mucous membrane for some hours. Another rod may then be inserted, and a suitable injection employed afterwards. This method is only of use, in my experience, before or during the inflammatory stage, and I employ it at any time till the inflammatory symptoms have disappeared, but generally within the first seven or eight days after the commencement of the discharge.

(To be concluded.)

## MITRAL STENOSIS IN THE GOUTY HEART.

By J. MILNER FOTHERGILL, M.D.,

PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK.

OUR knowledge of valvular affections of the heart does not rest on the detection of a murmur, its seat, the point of its maximum intensity, and its precise time in the cardiac cycle. Nor does their treatment consist in the administration of digitalis and iron promiscuously. Such simplicity may be admirably adapted to the requirements of an examination table, but it is perilously inadequate to the wants of actual practice. For the latter some familiarity with the natural history of each form of valvular disease is eminently desirable, which alone will enable the medical practitioner to read his case aright. There is first the individual to be estimated; then the disease to be measured. Then 2 and 2, or the nearest approach to that numeral in each case, have to be put together; and then 4 is the resultant product. But the equation has points of practical difficulty not represented in the mathematical formula. It is not always easy to determine the precise "2" of each factor. For instance, let me adduce the following case:—

E. A. W—, aged fifty-four, the mother of a family in a south-western county, came to me a little while ago, as her local medical man had found something amiss with her heart. She had been a very active person, but recently had not felt so equal to effort. Yet she had no shortness of breath on exertion, and only a little palpitation on effort at times. She had some dilatation with hypertrophy of the left ventricle, and beyond that a long mitral stenosis-murmur, heard to the right of the left apex; but over a limited area only. There were no indications of regurgitation. Now, what was the significance of this murmur? Was it—(1) The evidence of the contracting or sclerotic endocarditis of Rosenstein? was it (2) the result of an old-standing injury, the outcome of a bypast acute endocarditis? or was it

(3) a mere peculiarity; a sound produced at the mitral ostium, which had been, and was, and is, and will be, without any significance whatever? I am not ashamed to confess that the problem is insoluble to me. The symptoms were quite accounted for by her general condition, for she was bilious and somewhat malnourished. Any failure of power in her could be perfectly accounted for without the hypothesis of contraction of the mitral ostium. There was no thrill accompanying the murmur; but such is usual in the contracting endocarditis of middle age and advanced life. There was no irregularity in the heart's rhythm. Nor would the presence of irregularity or a thrill have cast the least ray or glimmer of light upon the case, in my opinion. There was the unmistakable murmur—seat, maximum intensity, period in time; and a long murmur to boot. The minutia of mitral stenosis are not recorded in my note-book. There was no possibility of mistake as to the presence of that murmur, which is held to be pathognomonic of stenosis of the mitral ostium. There was the murmur true; but what was the anatomical condition underlying it? That was the essential question to be asked; and, if possible, answered. The murmur in itself was nothing; but its cause was fraught with the most intense interest. With which of the three conditions spoken of above was it causally connected? I summed up the evidence against its being the outcome of a steady progressive diminution of the mitral ostium due to sclerosing endocarditis, and gave a prognosis accordingly. Whether the diagnosis and with it the prognosis was correct or not time alone can tell. The case was certainly one where contracting endocarditis might be present; for its associations were there as regards the general conditions; but the essential features of mitral disease were not sufficiently prominent to establish its presence.

From the negative aspect of a case like this it may be well to go on to describe the positive features of mitral stenosis in elderly persons. Assuming that some of my readers are not thoroughly familiar with the natural history and features of mitral stenosis in all its varieties, it may be well to point out that such mitral stenosis has very different features from the mitral stenosis of young subjects. Perhaps in the dead-house the features are more alike than they are clinically. In the mitral stenosis of the young, set up by acute endocarditis, there is the weak pulse of a small left ventricle; shortness of breath on exertion; enlarged right ventricle; tendency to dropsy in the serous cavities, or the lower limbs. Often there is the "heart-cough," of excess of blood in the pulmonary circulation. There is a murmur, presystolic in time, conveyed to the right of the left apex, often accompanied by a thrill. Such are the leading features. The case may get worse steadily, and even with considerable rapidity; or, as is more commonly the case, the patient is fairly well when quiet, but effort produces distinct shortness of breath, with palpitation. Anything which impairs the strength may elicit some œdema. But though the organism is crippled by the injury done to the mitral valve, the injury itself remains static, and manifests no tendency to go on from bad to worse; or if it does, it is immeasurably slowly. In such a case the administration of digitalis and iron would be likely to be of distinct service.

Now, as to the mitral stenosis of the gouty heart. Here there is a permanent high blood-pressure in the arteries, leading to hypertrophy of the left ventricle, with subsequent hardening of the arteries; the cardio-vascular changes which constitute the first stage of the granular kidney, so ably described by Dr. Mahomed in his recent thesis "Chronic Bright's Disease without Albuminuria." The hypertrophied ventricle contracts with vigour, so overcoming the resistance offered by full arteries to the cardiac systole and forcing the blood into the aorta, which on its recoil closes the aortic valves with a loud sound indicative of forcible closure; and this forcible closure frequently sets up valvulitis, with subsequent mutilation of the aortic valves. This association of aortic disease with the gouty heart is now well recognised. But the powerful contraction of the hypertrophied left ventricle causes also forcible closure of the mitral valves; they have to sustain a strain equal to the force required to overcome the resistance of the full aorta, and this strain tells upon them in time, leading to a slow sclerosing endocarditis. Such valvulitis may give either stenosis or insufficiency of the mitral valve. When the free edges become puckered and contracted, then insufficiency with regurgitation follows; when the valve curtains are soldered together by a slow inflammatory growth extending from the attachments of the valves, then stenosis with obstruction is the result. Now

whatever the form assumed by the valvulitis, the features of the gouty heart will remain to the end; even when all the phenomena of advanced mitral disease are developed and implanted thereon. The aspect is never that of simple primary mitral stenosis; nor does the interest centre round the murmur evoked by the morbid process, but attaches itself rather to the associated general condition of the vascular system.

A certain amount of injury to, and deformity of, the valves has gone on before it is sufficient to produce a murmur. But there may be the rational symptoms of a mitral lesion before the ominous murmur is set up. It may be possible to "suspect" a mitral valvulitis before the tell-tale murmur can be heard; there is, indeed, a pre-murmuric stage in all probability. It is no part of the design of the writer here to discuss this early stage, but to confine himself to the consideration of mitral stenosis—i.e., of a stage so advanced that it carries with it a murmur indicative of the character of the injury done. What are the features of this form of mitral stenosis?

The patient is elderly; has a more or less pronounced senile aspect. The complaint is that the power to undergo exertion is impaired. There is shortness of breath upon effort. There may be nothing more. The pulse may be feeble and rapid, but there is nothing else about it, nothing characteristic. But on auscultating the heart over a very limited area, at or near the right apex, a tiny "whiff" can be caught. Only over a small spot; move the stethoscope ever so little and it is apt to be lost; certainly lost if the stethoscope be distinctly moved. Here the presence of a murmur is significant, and unmistakable enough; at least in the majority of cases. But there is also a strong heart very commonly, and a fairly full artery—i.e., there are the associations of a gouty heart along with the mitral stenosis. Usually the nature of the cause of the murmur is clear and patent, and not a matter for reasonable doubt, as in the case given above. Here is a distinct explanation of the failure of power complained of. Or there may be a more advanced condition attained before the case came under notice, and the patient is confined to bed with or without some positive patch of pulmonary congestion. But there are the significant murmur, the rational features of mitral disease, linked with the cardio-vascular changes of the gouty heart, or granular kidney, as the case may be. The diagnosis bears on the prognosis and the treatment, especially as to the administration of digitalis. Here there is not an old-standing limited injury to valves, as static and non-progressive as the scar of a burn; limiting the patient's powers, but possessing no tendency to further advance. There is a contracting or sclerosing valvulitis afoot, which tends to steadily go on from bad to worse, because the mitral valve has to bear the strain put upon it by an hypertrophied left ventricle. It is a progressive form of valvulitis. Certainly; but granting that, at what rate is it progressing? "*Quien sabe!*" as the Spanish girl said when they asked her who was the father of her child" (Kingsley). One would like to know; but how can one get to know? Only, in the language of Oliver Wendell Holmes, by getting "an arc big enough to determine the size of a circle"—i.e., getting a period of observation long enough to calculate the rate of progress. This may entail personal observation, or may be fairly made out by the history of the case. In one case a definite date can be made out, since which there has been such a falling-off in the patient as reveals pretty plainly the time when the lesion began to tell upon the organism. In another case there will be no data pointing to any special time when the health was obviously impaired. The patient is not very well, feels weak and unequal to exertion, and is scant of breath, and on examination of the chest the murmur of mitral stenosis is audible. Such a case presented itself to me in June, 1880.

A gentleman, aged sixty-seven, who had led an active life, but who latterly had pains which he called "rheumatic," though, he wrote, his "water is more or less high-coloured, and the red sediment is always round the bottom of the pot," which looked like gout—came to me for some "fluttering or palpitation" at the heart. The diagnosis then made was "gouty heart, with mitral stenotic murmur." He was put upon a pill containing some strychnia and digitalis. On this treatment he lost his uncomfortable sensations, and felt very nicely. He went abroad for some time, being conscious of his heart only by some shortness of breath on attempting to climb a hill. A year later he was nicely; his tongue clean, and urine clear; not perceptibly worse. This June he presented himself after an attack of bronchitis,

which had pulled him down considerably. The heart was acting irregularly, and the beats were unequal in force. This was due to muscular debility in the heart, the right heart having been severely taxed by the extra demand upon it made by the bronchitis. He had been given carbonate of ammonia, nux vomica, and digitalis by his medical man, according to the formula at p. 367 of the "Practitioner's Handbook of Treatment" (2nd edition), which had suited him well. Indeed, he feels so well that he will not give the heart the rest required for it to recover itself. On his old pill he is doing well, and the muscular tone of the heart is being regained.<sup>1</sup> Even with the recent demand upon the heart there is no evidence that the mitral lesion is perceptibly advancing. In some other cases the inactivity of the valvulitis seems about the same; but in others, again, the progress has been steadily, if not rapidly, downwards. In one case there are violent paroxysms of angina pectoris present.

As to the treatment of these cases, the prevention of the production of uric acid by an appropriate dietary and the use of hepatic stimulants, its solution by antilithic alkalies, are measures about whose adoption there can be no question. To keep the blood-pressure in the arteries as low as possible means lessening the strain on the diseased mitral valves on each ventricular systole; and this is attained by reducing the amount of albuminoid waste in the blood, or dissolving it and so letting it escape by the water emunctories. So far so good. But how about the administration of digitalis? To increase the vigour of the ventricular contractions means increase of the strain on the valves. Certainly; and therefore grave and valid doubts may honestly be entertained about the wisdom of giving digitalis and iron, in a routine manner, in all such cases of mitral valvulitis. When the heart is fairly vigorous, and there are none of the rational symptoms of mitral mischief present, then, probably, it is well to withhold the digitalis and to be content with an appropriate dietary and regimen. But when there are evidences of cardiac failure, then, in all probability, it is well to give the digitalis; albeit in doing so the ventricle does strike harder, and so tax more the mitral valves. Here the ventricle is striking feebly, and the advantage of improving the heart's vigour is not more than counterbalanced by further strain put on the sclerosing valves. In practice each case must be decided by its own indications; and the indications will vary at times in the same case. Nor is it possible to lay down any rules of thumb for the administration of digitalis. The practitioner must weigh carefully the indications for its adoption or the withholding of it in each case. It is not necessary or desirable to give it merely because there is a mitral murmur present; as Rosenstein puts it, "Digitalis helps the heart to pump the blood out of the veins into the arteries," and the fulness of the veins and the comparatively empty state of arteries are the indications for its exhibition; no matter what the murmur, or whether there be a murmur or not. Probably when the rational symptoms of mitral mischief are present it will always relieve them. Whether at times such relief is antagonistic, or prejudicial to the ultimate interests of the case, and therefore it is better to withhold digitalis, is a matter for the exercise of private judgment on the part of the medical adviser. This is certain, the indications for digitalis in such mitral stenosis (or insufficiency, too, for that matter) are not so unmistakable as is the case in mitral valvulitis in the young, where a distinct injury, be the same more or less, has been wrought; but where there is no tendency in the valves to further mutilation, the distorting process being over and done with, the said injury crippling the organism and leading to death from the disturbance so wrought in the circulation, here digitalis can scarcely do any harm; but the same cannot be said of the sclerosing valvulitis of the gouty heart.

<sup>1</sup> Since writing the above he has had some distinct gouty symptoms.

THE family of the late George Henry Lewes have (says the *Athenæum*) presented the philosophical and scientific portion (over 2000 volume-) of his library to Dr. Williams's trustees in order that the books may be available to special students at the library in Grafton-street. The only condition attaching to the generous gift is that the books be arranged on distinct shelves, and that each volume bear some record that it formed a part of the "George Henry Lewes Library."

## ON THE USE OF VENESECTION IN CASES OF HEART DISEASE.<sup>1</sup>

By BEDFORD FENWICK, M.D., M.R.C.P.,

ASSISTANT PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES  
OF THE CHEST, PATHOLOGIST TO THE HOSPITAL FOR  
WOMEN, SOHO-SQUARE.

"It would be difficult," wrote Dr. Marshall Hall nearly sixty years ago, "to determine whether greater injury has risen in the practice of phlebotomy from undue or from inefficient bleeding. To neglect the full use of this most important of our remedies when it is required, or to institute it when it is not so, is equally to endanger the safety of the patient." When that celebrated teacher and practical physician uttered these weighty words, he could proceed to say: "It sometimes requires no little boldness to abstain from the use of the lancet." Bloodletting is not only the most powerful but the most generally used of all our remedies." How essentially and widely different our teaching and our practice is now need hardly be insisted on. A distinguished practitioner told me the other day that he had never drawn an ounce of blood, or even sent a cupping-glass in all his life. A clinical teacher will name twelve drugs as useful in heart disease, but never once, perhaps, suggest a single leech. In fact we seem to shrink from the lancet as if it were an assassin's dagger, and to look upon the bleeding basin and the measuring tabe as murderous relics of a bygone and a barbarous age. I verily believe that the whole question of venesection in disease has yet to be settled upon a scientific basis. I only hope to treat it as regards affections of the chest, and at present I would only draw attention to the immense benefit derived from its discriminate use in cases of heart disease. I hoped then to be able to show that in venesection, rightly used, we indeed have a "most important," a "most powerful" remedy; and I need hardly add, perhaps, a most neglected and far from a "most generally used" one. It may not be altogether uninteresting to tell how this great truth was forced upon my attention; because, brought up like most men nowadays in the strictest sect of the anti-venesectionists, I frankly confess that I was wont to read accounts of how our fathers were bled semi-annually or oftener, with a sense of quiet satisfaction at our own much greater wisdom.

CASE 1.—Albert L.—was admitted into the London Hospital under the care of Dr. Andrew Clark, when I was acting as his house-physician. He was twenty-three years old and had suffered from rheumatic fever. On admission he was very ill. Stenosis of the mitral orifice and incompetence of the aortic valve with œdema of both lungs were diagnosed. There was very considerable dyspnoea and general œdema, but no marked cyanosis or turgescence of the jugular veins. The urine was very scanty, and despite all our remedial efforts did not increase in quantity. In fact the kidneys seemed "clogged." Digitalis, ether, and senega were given in a mixture three times a day. The bowels and the skin were kept freely acting. He was kept strict in bed on restricted diet. The lungs certainly at first cleared up somewhat, but at the end of a month his general state was none the better, but rather the worse. Then the urine became scantier, the œdema increased, he became drawy, and coma seemed supervening. I was going round the ward late at night, and was just passing the man thinking to myself "no more to be done there," when it suddenly struck me to get a tracing of his pulse. In adjusting the sphygmograph the patient slightly roused, threw up his other hand and struck his nose heavily. It at once began to bleed. Thinking that in his state it could do him no harm and would probably stop at once, I put a towel under his cheek and went on with my work. Having leisurely taken about half a dozen tracings I removed the instrument and fixed my slides. I was then surprised to observe that the last one or two tracings were wonderfully steadier, more even and regular throughout than the first one or two. Involuntarily I went back to the bed. The towel under the man's cheek was soaked right through with blood. He must have lost at least twelve or fourteen ounces, and the bleeding must have been very rapid while it lasted, for it had now ceased. He lay

there looking at me wide awake and perfectly conscious, breathing quietly, with soft, slightly jerking pulse, and calmly said that he had had a good sleep, and felt better for it. Next morning I went in at an early hour to see him. He was sitting up in bed, and complained bitterly of being kept there. He said he had been passing urine all night long. His pulse was still soft, and his breathing quiet, and for him wonderfully easy. In less than a week the œdema was perfectly gone, his pulse was 80, his respiration 24, his appetite was becoming voracious; and he insisted upon returning home, feeling better, he said, than he had done for months. The ridiculous side of the story remains to be told. No one had noticed the bleeding except myself, and I never thought of naming it. I afterwards heard, however, that his rapid recovery was attributed both by himself and his fellow-patients to the mysterious clockwork operation performed on him that midnight by the magical sphygmograph.

Now, I venture to consider that this case is a very important one. Many practical physicians would, and do, say if there is great blueness of the face, or pulsation of the jugular veins, or such like evidence of obstruction to the passage of the blood through the right heart—bleed, to remove part of the excessive forward pressure. But there they stop; and here we had no cyanosis, no jugular distension. We had, however, evident blood stasis in the cerebral and renal organs; and it will not be denied, I think, that the epistaxis saved the patient's life. It is perfectly plain, therefore, that we imperatively need, and must have, some definite scientific principles laid down applicable to all cases of heart disease. In attempting to do this, which I cannot find has ever been done before, I deeply feel my own incompetency to the task, and, indeed, attempt it here not by any means with the hope of settling the question, but rather of raising it as a matter of the most vital interest to every patient with heart disease, and to every practitioner who may have to treat such a case. And first with regard to chronic valvular disease, of which we have naturally two great classes, those with contraction and those with insufficiency of the valves. In both classes we have one common sequence to ward off, the onset of dilatation; and one common danger to guard against, the occurrence of fatty degeneration of the muscular walls. I need hardly point out here that loss of blood is a most common cause of fatty degeneration, and that once this fatal metamorphosis has commenced dilatation rapidly ensues. I may, however, mention that I have observed that fatty degeneration seems to occur, as a rule, much earlier, and to a more extreme degree in cases of incompetency of the valves than in cases of stenosis of their orifices, from which it follows that we must bleed more carefully and less often in cases of valvular incompetency than in cases of stenosis. With regard, now, to the latter class. Common sense would almost seem to dictate the advisability of keeping the blood to be forced through an abnormally small opening abnormally small in quantity. Now, probably, every practitioner of any standing knows how cases of mitral stenosis, for example, may go on in comfort and fairly good health year after year, and yet always seem rather anæmic, and how a single indiscretion in diet, or a trivial attack of bronchitis, will so upset the evenly balanced circulation as to bring the patient in a few hours into grave peril of his life. I am firmly convinced that in such cases venesection is invaluable, and that on the slightest indication that the balance is trembling we shall only and alone do justice to our patient if we remove the cause by removing blood; and it is wonderful how little need be taken to give rapid and often long-continued relief. Therefore, having regard also to our foe, fatty degeneration, I would venture to suggest this clear rule—in cases of stenosis, if necessary, bleed at once; bleed often, if requisite, but take little each time.

CASE 2.—Mary R.—aged fifteen, was admitted into the London Hospital in July, 1879, under the care of Dr. Andrew Clark, suffering from intense dyspnoea and cyanosis. The extremities were cold; there was considerable œdema of the legs. The urine was very scanty. The pulse was scarcely perceptible, though the heart's action was powerful. There was a presystolic thrill and murmur audible at the apex, and a systolic bruit at the base.

On July 10th, in addition to the above symptoms, she became very drowsy and hard to rouse, and it seemed probable that coma would supervene. She was bled from the right arm to the amount of four ounces and a half, when she roused herself and declared she felt much better. The breathing certainly was easier, and the lips became less blue, and the pulse softer and distinctly fuller. On the following

<sup>1</sup> Read before the Hunterian Society, March, 1882.

day, however, dyspnoea came on again, and she was bled from the left arm to three ounces, when she expressed herself as feeling much relieved. A rapid increase in the daily quantity of urine at once began, and the oedema quickly diminished. She, however, felt so well that, against orders, she got out of bed, walked about the ward in an undressed state, and caught cold. Acute bronchitis set in, and the dyspnoea returned. On the 19th she was accordingly bled from the right arm to three ounces, with great relief to the breathing. The bronchial trouble rapidly cleared up, and she declared that she felt better than she had done for months. I was now invalided myself, and she passed into the charge of a very able locum tenens. He, however, did not believe in venesection, and when on the 29th, after fresh exposure and a fresh cold, she sank into the same state as described on July 10th, she was not bled. She became comatose, and died the same evening.

The post-mortem revealed the accuracy of the diagnosis—a very extreme degree of mitral and aortic stenosis being found. As on every occasion when blood was removed, the patient was in urgent danger, and as each time only a small quantity was taken, and yet nevertheless each time with great relief, the whole case, I think, amply supports the practical lesson that I above pointed out. Latterly, I have only used leeches or cupping to remove blood directly from the cardiac region in cases where stenosis existed. I imagine that we obtain thereby more certain and more rapid results with a more accurate loss of blood than when venesection from the arm is resorted to. Still this is a matter of such great practical importance to the patient's welfare, and to our own success, that I feel bound to state distinctly some reasons for my judgment:—1. The patient, and the patient's friends, usually object less when leeching or cupping is suggested, than when "bleeding" is proposed, and they are less alarmed at a local application to the seat of disease than at the procedure necessary to open a vein and keep it bleeding. 2. The quantity of blood to be abstracted can be more accurately measured and controlled, and is generally much more easily obtained in cases of advanced stenosis by local than by brachial venesection. 3. Even as, like all practical men, I give a hypodermic injection of morphia at the seat of pain, although I cannot explain why its insertion there should give so much greater and more rapid relief than when introduced into the same blood at a distance, so I cannot explain why a little blood removed from the cardiac region should afford greater and quicker relief than is derived by the abstraction of even a somewhat larger quantity from the arm. I do the former and leave the latter undone in these cases, because I am convinced of the great practical truth that thereby greater good is gained.

CASE 3.—William H—, aged fifteen, was admitted into the London Hospital, in 1880, suffering from contracted mitral and aortic orifices, dilated left ventricle, and bronchitis. A mixture, containing digitalis, ether, squills, and senega, was given. Absolute rest in bed and restricted fluid diet was ordered. He improved somewhat, but very slowly; but at the beginning of March he began to suffer from increasing dyspnoea, and became rather cyanosed. On March 4th his breathing was rapid; he was drowsy and hard to rouse; his pulse was scarcely perceptible; while his heart's action was laboured, heaving, and irregular; his face and hands were covered with a cold sweat; his breath was cool; he seemed moribund. I put a number of leeches on the cardiac region, and they were very freely fomented. When they had bled to about six ounces, he roused himself a little and said that the pain at his heart was almost gone. In an hour or two his pulse was 80, weak still, but decidedly fuller than it had been for days past. I now increased the dose of the infusion of digitalis from three to four fluid drachms thrice a day. And I may here say how often I have been astonished to find how drugs which had been given for days or weeks without apparent benefit, as soon as even a little blood has been removed, seem at once to assert their power again. The patient now rapidly improved. In a week he was out of bed; and on March 23rd he was discharged, feeling better, he said, than he had done for months past. I might easily multiply cases, but I think these amply illustrate the principle I desire to enforce.

With regard now to incompetency of the valves. Here we have, I believe, a more dangerous form of disease. For I am convinced that we have in such cases a greater tendency to the early occurrence of dilatation, and, therefore, of sudden death. And so it appears to me that we should only

bleed in such cases when there is urgent dyspnoea, or other evidence of danger. Further, that then we should bleed boldly from the arm till that danger is removed, and for fear of inducing a state of fatty degeneration of the already weakened muscular walls, that, if possible, the bleeding should not be repeated. For in this class of cases we do not want to keep up a permanent effect—that is to say, a constant restriction of the quantity of blood in the body; but we have to counteract, and suddenly may be, an imminent peril. That venesection, however judiciously used, is most beneficial in these cases is amply evidenced by such as the following:—

CASE 4.—Thomas C— was admitted into the London Hospital on May 21st, 1867, under the care of Dr. Ram-kill. On entering the hospital he was found to be suffering from aortic regurgitation, emphysema, and acute bronchitis. His urine was albuminous. At 3 P.M. on the day of admission his face and neck were livid; his eyeballs projected, and his lips were bloated looking. The veins of his neck were very much distended. His skin was perspiring and felt cold. His pulse was small, irregular, and quick. Respiration forty a minute, and his breathing was so laboured and quick that he could hardly speak. At midnight on the day of admission he was much worse; his face was livid, his breathing gasping. His face was covered with cold sweat, and his pulse could hardly be felt. He was bled to sixteen ounces, and at once he expressed himself as feeling relieved. His breathing in the course of an hour became much freer, and he was able to sleep a little. Next day he looked much better, he appeared altogether a different man. His pulse was still very irregular and quick, but his respiration was slower. He continued to improve and left the hospital very much relieved. He returned in two months in much the same state as before. He was bled to fifteen ounces, with considerable temporary relief, but died suddenly five days afterwards.

CASE 5.—"A costermonger,<sup>1</sup> aged sixty-two, was admitted, under the care of Dr. Herbert Davies, suffering from tricuspid incompetency and dilated right heart. He was extremely livid in the face; it might fairly be said to be of a purple colour. The superficial veins were dilated. The dyspnoea was so great that he could not lie down. He sat on the edge of the bed, nodding, in a kind of stupor, the whole day long. Expectant medicines were tried without any relief, and the dyspnoea increasing every day he was bled to 14 oz. He expressed himself as much relieved, and there was a marked decrease in the lividity. The dyspnoea was much relieved. He felt so much better that he insisted upon being discharged from the hospital. After being out a few weeks he returned in much the same state as at first. He was again bled from the arm, and greatly benefited, and he left the hospital. After about two months he was again admitted, under the care of Dr. Andrew Clark, in even a worse condition than before. He was bled again, but without relief, and he died very soon after."

In each of these cases the post-mortem revealed considerable ventricular dilatation. Besides the above, Dr. Sutton quotes other illustrative cases, and Dr. Dickinson has recorded one in the Pathological Society's Transactions. I would, however, while fully recognising the great benefit obtained in the above cases, point out that a sudden death in each followed rapidly on a venesection. In private practice the chances would be that in such a case the fatal result would be laid on the doctor's shoulders; and therefore, for a double reason—for the practitioner's as well as for the patient's welfare,—the rule above suggested should be kept in mind till a better one is laid down for venesection in cases of valvular incompetency.

Next, with regard to acute pericarditis and endocarditis. I have not had the opportunity of using venesection in many such cases, but where I have done so I have invariably bled by cupping the cardiac region, and always with good result—so successfully, indeed, as to make me believe that if this measure be taken at the onset of the disease it will very often if not always cut the attack short, or at least greatly mitigate its severity.

CASE 6.—Thomas H—, aged twenty-eight, was admitted under the care of Dr. Clark, suffering from dyspnoea and a slight grasping pain over the cardiac region. The heart's action was rapid and excited, and there was a rough, rubbing friction sound audible over the whole cardiac area. He was cupped at once to eight ounces, and expressed himself

<sup>1</sup> Medical Times and Gazette, Dec. 18th, 1866, p. 707.

greatly relieved. The next morning the heart's action was quiet and regular, the rubbing sound had completely disappeared, and no evidence of effusion having occurred ever showed itself.

Finally, with regard to that troublesome symptom in heart cases—pain more or less severe, more or less persistent in the cardiac region—I have found nothing give such complete and rapid relief as the local abstraction of blood. Whether the symptom arises from local hyperæmia or not I do not profess to know, but of the great practical value of the remedy here I am firmly convinced.

CASE 7.—A young gentleman was brought to me a few weeks ago. He had been seen by several eminent specialists, and was, as I afterwards found out, under the care of a justly distinguished practitioner. He had old mitral valve disease, but for some weeks past had suffered from extreme aching and often agonising pain localised to the cardiac area. I could detect no sign of pericarditis. The temperature was only 99° F. There was no tenderness on pressure, no herpes; in fact, there was nothing to account for the pain. His parents and friends were much depressed because blisters and poultices, ether spray and galvanism, and a host of other remedies and drugs had been tried, but without the slightest alleviation of the pain. I prescribed a mixture containing belladonna and digitalis, and recommended that he should be cupped to seven ounces over the cardiac area. I have since heard that this was done with complete and immediate, and till now permanent, relief from pain.

To summarise, then, I would conclude that:

1. In cases of valvular stenosis, if dyspnoea or pain or urgent symptoms be present, bleeding is generally useful; that it appears to be better to bleed often if necessary, but to take only a small quantity each time, and this by means of leeches or the cupping glass direct from the cardiac region.

2. In cases of valvular incompetency, if urgent dyspnoea or cyanosis or stupor be present, it appears best to bleed freely from the arm to about sixteen or twenty ounces if necessary, and if possible once for all.

3. In cases of acute pericarditis and endocarditis the attack may possibly be cut short by freely cupping the cardiac region at once.

4. In cases of cardialgia, without any evident cause, leeching or cupping over the heart's area will probably give relief.

West-street, Finsbury-circus, E.C.

## THE TREATMENT OF ACUTE CHOREA BY "MASSAGE" AND THE FREE ADMINIS- TRATION OF NOURISHMENT.

By JAMES F. GOODHART, M.D., F.R.C.P.,  
ASSISTANT-PHYSICIAN TO GUY'S HOSPITAL, AND PHYSICIAN TO THE  
EVELINA HOSPITAL FOR CHILDREN;

AND

JOHN PHILLIPS, B.A., M.B.,  
ASSISTANT-PHYSICIAN TO THE CHLSEA HOSPITAL FOR WOMEN,  
AND LATE RESIDENT MEDICAL OFFICER TO  
THE EVELINA HOSPITAL.

THE treatment of chorea has never been uniformly successful or flattering to the skill of the physician. When examined from the standpoint of the non-professional mind, there is not often any obvious relation between the drugs swallowed and the lessened muscular movements; and chorea drags its slow course along, disheartening alike the doctor and the parents of his patient. In all probability, what chorea has proved in the past with respect to treatment, so in many cases it will prove in the future. It is not a disease to which speedy cure is applicable or possible. It may almost always be improved, and considerably so by many forms of treatment. Still none are so satisfactory but what others may prove useful in properly selected cases, and thus it is that one is always willing to try anything new.

The object of this paper being purely a clinical one, the interesting question of the nature of chorea must be passed by; for present purposes we shall content ourselves by saying that it is a nervous habit, which, by neglect and nerve exhaustion combined, becomes aggravated into an acute disease.

Thus thinking, Weir Mitchell's plan of treating the nervous exhaustion of women as detailed of late by him and by Dr. Playfair seemed one that might possibly be productive of good results, and it has accordingly been carried out, perhaps not always quite strictly, in two cases that have been admitted into Guy's Hospital for that purpose, and in a series of ten cases at the Evelina Hospital. The Evelina Hospital cases constitute in fact the total of Dr. Goodhart's cases there during the past nine months, with the exception of three which suffered from heart disease and fever, of such severity that they speedily proved fatal—for such as these the treatment is not applicable—and four or five which were not of such severity as to afford a fair test of the treatment. Weir Mitchell's treatment, it will be remembered, in the case of women, is one of absolute rest, so far as voluntary movement is concerned; of the supply of nourishment in large quantity; and of the exercise of the skin and muscles, by what is now called "massage," but which let us call, as of yore, shampooing. It can hardly be called new as regards chorea, so far as the individual factors of it are concerned; perhaps there is more of novelty in the combination of these and in the aim which suggests it. Choreic children are the subjects of a faulty habit; are badly educated so far as their nervous system is concerned. Once choreic is to be always so, more or less, and it is education—practice, that is, in the art of muscular control—which such children require throughout life. But acute chorea is a bad habit and much more, and education under the circumstances of violent chorea is not only useless but harmful. The more a child is incited to voluntary muscular movements the more it moves choreically, and by so much tends to perpetuate the aggravation of its habit, and, as is well known, simple rest in bed will often much ameliorate the violence of the choreic movement. But to passive movement there are few objections, and for it may be claimed some very distinct advantages:—1. If carefully performed the muscles, flabby and poor in these children, become plump and healthy. 2. The various groups being manipulated in an orderly manner, some influence will probably be exerted towards restoring more equable nerve discharges from the centres which control them, and displacing a disorderly habit by an orderly one. 3. The supplies are utilised to their utmost without call upon the diminished capital of brain power.

Each case has been kept at rest in bed without other treatment of any kind for the first two days, in order that the amount of erratic movement under such conditions might be observed. Then shampooing has been commenced and feeding has been pushed in gradually increasing quantity, with the hope that a more healthy brain might be built up on the one hand and more regular habit induced on the other.

No one who knows anything of chorea will suppose that the success has been in all cases convincing, but some advantages may certainly be claimed for the treatment, and we think it is one which deserves a trial. The chief of these are:—1. A decided increase in weight. 2. Rapid subsidence of all the more violent movements, and it has happened that after two or three days' treatment a child quite uncontrollable has been able to sit up in bed, in a fairly quiet mind. 3. The extremities are no longer cold, and as a further evidence of the good influence on the circulation, the pulse falls and becomes more regular. 4. Shampooing is a powerful sleep producer; children as a rule sleep soundly after being shampooed. It might have been supposed that the patient would be frightened and dislike the treatment, but this has never been the case, nor has there at any time been any dyspeptic disturbance to indicate that the digestive organs have been over-taxed by the excess of work they have been called upon to perform. We make no statement with reference to the actual duration of the cases, because this is a treatment for chorea in the active stage; and when it has been successful there is still a range of lesser movement which must be covered by subsequent careful education, which must always make a prudent man chary in his use of the word "cure," and it will be better on this head to let each case speak for itself. For the rest, to Dr. Phillips belongs all the credit of carrying out the suggested treatment, and of reporting the cases in the most careful and elaborate manner, as will be seen from what follows.

We purpose to give a full report of one case, showing the course of treatment pursued, and the diet-tables used, and then to give an abstract of the remaining cases in order. On admission the patient is put into a padded bed. Milk

only is given for three days; during this time the movements are carefully watched, grasping and articulating power noted, and bowels regulated. If the movements show no sign of abatement, massage is begun twice daily for fifteen minutes for the first seven days, and for twenty minutes afterwards. The diet-table for the first and second weeks is given below. The temperature and pulse are taken immediately before and after massage. The patient is weighed every week.

CASE 1.—Alice O—, aged ten years, was admitted on Feb. 18th, 1882; second attack; history of acute rheumatism on maternal side; first attack very slight, but lasting nine months; supposed cause a dog flying at her. The present attack began more than twelve weeks ago; twitchings have been getting rapidly worse; loss of articulation occurred six weeks ago; the patient has had night terrors during the last seven days; she has been in bed during the last month, but seems to get worse; during the last six weeks has been treated with digitalis and iron. Condition on admission: She cannot walk; throws herself about in bed; tongue bitten; no grasping power; cannot articulate; bursts into a paroxysm of shouting and crying if looked at; cannot swallow, the food dribbling out of her mouth. There was a presystolic and systolic murmur at apex. On Feb. 19th and 20th she was quite uncontrollable; took no food; knuckles abraded; sacrum and other prominences reddened; no sleep at nights; anxious expression; considerable pain in head. Massage began on Feb. 21st; weight 3 st. 10 lb. 10 oz.

Diet: At 5.30 A.M. half a pint of warm milk; 7 A.M., half a pint of milk and three slices of bread-and-butter (each slice to weigh 1 oz.); 9.45 A.M., half an ounce of Kepler's malt extract in lemonade; 10 A.M., massage (fifteen minutes), followed by half a pint of warm milk flavoured with cinnamon-water; 12.30 P.M., rice pudding, half a pint of milk, green food and potatoes; 4.15 P.M., half a pint of warm milk, three slices of bread-and-butter, and one egg (half boiled); 7 P.M., half an ounce of Kepler's malt extract in lemonade; 7.30 P.M., massage for second time, followed by half a pint of milk immediately.

	After „	63 ...	95.8°	72 ...	95.6°

<sup>1</sup> Much quieter after morning massage, and slept well for six hours during the night.

<sup>2</sup> Was spoken to and handled without any emotion; has complained of no pain; does not object to massage in the least.

<sup>3</sup> Movements are already diminished; she can take milk with much less "slobbering"; articulation better.

<sup>4</sup> Tongue protruded much more regularly; tongue has not been bitten; no night terror.

<sup>5</sup> "Systolic" murmur very slight, and presystolic has disappeared; can articulate the word "Better" when spoken to.

<sup>6</sup> Systolic bruit has quite disappeared; can to-day articulate her name; takes all her food well; tongue protruded straight; grasping power weak.

<sup>7</sup> Weight 3st. 11lb. 12oz.

All active movements have ceased, and she has now nothing but the occasional twitching usual in these cases. Massage was kept on for fourteen days longer, in the hope that these too might disappear, but although they were materially lessened, and entirely ceased in three weeks, the diminution was scarcely marked enough to say that it was caused by the treatment.

CASE 2.—Eliza G—, aged nine years. Third attack. Strong history of acute rheumatism on paternal side; no cause. Condition on admission: Tumbles down; great headache; night terrors. Palms in her limbs; muscles flabby; skin rough and dry; loud systolic murmur at apex. Weight 3 st. 6 lb. 6 oz. After eight days' massage all violent movements ceased; headache and night terrors disappeared; skin supple and moist. Weight 3 st. 7 lb. The massage was continued, as in Case 1, and certainly with better results.

CASE 3.—George S—, aged seven years. First attack. Acute rheumatism on maternal side; strong history of epilepsy in father; no cause. Condition on admission: General movements; strabismus. Cannot feed himself; continually grinding teeth. Night terrors. Slight systolic brush at apex. Weight 3 st. 3 lb. 4 oz. After ten days' massage movements scarcely perceptible. Night terrors ceased. Weight 3 st. 4 lb. After twenty-one days' massage movements had entirely ceased. Weight 3 st. 4 lb. 10 oz.

CASE 4.—Maude G—, aged seven years. First attack began four months ago, after having her ears boxed; since then she has become mischievous and spiteful; movements sometimes very severe, at others slight. Condition on admission: General chorea; cannot stand. Heart sound normal. Cannot hold anything; milk dribbles out of her mouth. Weight 3 st. 10 lb. After seven days' massage all severe movements ceased. Food taken well; holds her own spoon. Weight 3 st. 10 lb. 5 oz. Continued massage had scarcely any effect on minor movements, which gradually ceased in twenty-one days.

CASE 5.—Henry C—, aged seven years. First attack. No rheumatic history, but epilepsy in a sister who died in a

<sup>8</sup> Last night some Kepler's malt extract was given which had been open for some time; this caused an epidemic of diarrhoea in these patients taking it. A mixture of opium and bismuth was given, and massage was stopped for three days.

<sup>9</sup> The systolic murmur has returned. In consequence of this illness she lost 1lb. 3oz. (3st. 10lb. 9oz.)

<sup>10</sup> Diet as before, except at 7 A.M. half a pint of warm milk and four slices of bread-and-butter; 12.30 P.M., chop (meat cut from bone, no fat), rice pudding, &c.; 4.15 P.M., half a pint of warm milk and four slices of bread-and-butter, another pint of milk distributed over the twenty-four hours.

<sup>11</sup> All difficulty in swallowing has disappeared; systolic bruit scarcely audible; movements much less.

<sup>12</sup> Fed herself twice yesterday, can articulate ordinary sentences.

<sup>13</sup> Takes all her food well; sits up in bed; is able to hold a spoon.

<sup>14</sup> Muscles have become no resistant, from increase of their volume and tone, that massage is very difficult; sleeps well all night and an hour or so after morning massage.

<sup>15</sup> Weight 3st. 12lb. 10oz., an increase of 2lb. in seven days.

fit. The patient seems *non compos mentis*. Cause over-study. Movements began three weeks ago. Condition on admission: Cannot stand; movements very violent; attempts to bite anyone going near him. Cannot feed himself. Heart sounds normal. Weight, 3 st. 2 oz. He became uncontrollable during the first three days, but at the end of the first massage he slept one hour and improved rapidly. Fourteen days after massage was begun his weight was 3 st. 2 lb. 2 oz. Took food well; movements scarcely perceptible. No further improvement was obtained by seven days' additional massage.

CASE 6.—Elizabeth S.—, aged nine years. Strong history of rheumatism on the maternal side, and of epilepsy in the father. Brother died of tubercular peritonitis. Has been in bed for the past three weeks; no cause. Condition on admission: Dyspnoea on exertion; good deal of frontal headache; facial muscles in continual motion. Cannot stand. Heart sounds normal. Weight 3 st. 7 lb. 12 oz. After twelve days' massage her weight was 3 st. 10 lb. 2 oz. All headache and facial movement disappeared. General movements very slight. Entirely cured after twenty-one days' massage.

CASE 7.—Annie H.—, age seven years. Cause a fright; duration of illness two months. No family history of importance. Condition on admission: Stumbles, but does not fall. Bites her tongue. Frontal headache. Night terrors. Dyspnoea on exertion. Distinct purring bruit at apex, and reduplicated second sound. Grasping power *nil*. Weight 3 st. 4 lb. 6 oz. After fourteen days' massage weight 3 st. 6 lb. 8 oz.; no night terrors; takes food well. Heart sounds *in statu quo*. No further effect could be produced, and this was one of our decided failures.

CASE 8.—William T.—, aged four years. Acute rheumatism on mother's side, with cardiac disease. No cause. Duration of illness five days, the movements coming on suddenly. Condition on admission: Cries passionately if touched; tumbles if allowed to stand; cannot articulate, but makes a noise of a nasal character; cannot feed himself or hold anything; passes everything unconsciously; movements were so great that it was impossible to take his temperature. Weight 2 st. 5 lb. Heart sounds: Slight post-systolic brush at apex. After seven days' massage he could feed himself; articulated indistinctly; tongue protruded straight; post-systolic brush has disappeared; motions and urine passed consciously; movements very slight. Weight 2 st. 5 lb. 8 oz. Fourteen days' further massage increased his weight to 2 st. 6 lb. 12 oz., and improved his articulation, but no other improvement was noticed.

CASE 9.—Florence G.—, aged nine years. One sister had chorea; duration of illness three months. No history of rheumatism; cause a fright; has been in bed during the last three weeks. Condition on admission: Cannot stand; movements very violent; crying with headache; heart sounds normal. Weight 3 st. 8 lb. 12 oz. After seven days' massage movement had almost ceased; headache gone. Weight 3 st. 9 lb. 12 oz. After fourteen days' massage was allowed to get up. Weight 3 st. 11 lb. No return of movements brought on by getting up.

CASE 10.—Harry C.—, aged nine years. Family history unimportant. Illness began three weeks ago with pains in ankles; two days ago lost all power of articulation; no sleep at nights. Condition on admission: Tumbles down if placed on his feet; grasping power *nil*; cannot hold a spoon. Headache severe; large callous patches on knuckles of fingers; right arm almost useless. Weight 3 st. 6 lb. 4 oz. After fourteen days' massage all headache had disappeared; movements quite ceased; has some grasping power in right arm. Weight 3 st. 9 lb. 4 oz. After nineteen days' massage he was allowed to get up, with no return of his movements.

CASES 11 and 12 were treated at Guy's Hospital. The one was a young woman and the other a girl of nine or ten, and in both the results were similar to those noted in the foregoing, chiefly the quieting of the more violent movements and the tendency to sleep induced by the massage.

The amount of urea excreted was tested daily, but no increase or decrease could be found to correspond with the increased nitrogenous waste.

From the above cases it will be seen that in four of them (1, 3, 5, 8) the treatment had a most marked result, and we believe it was influential in saving the child's life. In all the treatment produced some good effects, general or other, and in several even upon the chronic movements, except, perhaps, in Case 7.

We must in conclusion once more insist on the fact that

the treatment we advocate is for the acute stage of chorea, not the chronic, although (as will be seen from perusal of the above) much benefit may indeed be derived from it, even in these latter cases. "Massage" and the mode of performing it is well described in Weir Mitchell's book, "Flesh and Blood, and how to make them." There are two or three essential points, however, to bear in mind: 1. Fifteen minutes twice a day, increased at the end of seven days to twenty minutes, is as much as the strongest child will bear. 2. After the operation the warm milk should be given and the bed-curtains closed, and all noise stopped, sleep then generally follows. 3. Neat's-foot oil, if used alone, often produces small boils, which cause the patient a good deal of discomfort. A mixture of an equal amount of olive oil will be found to obviate this trouble. 4. Care should be taken to give the Kepler's malt extract *fresh*. If any fermentation has taken place troublesome diarrhoea will probably result.

## AN EASY METHOD OF DETECTING BACILLUS TUBERCULOSUS FOR DIAGNOSTIC PURPOSES.

BY HENEAGE GIBBES, M.D.,  
CURATOR OF THE MUSEUM, KING'S COLLEGE, LONDON.

SINCE the publication of Koch's discovery of an organism in phthisis and his method of demonstrating it, many experiments have been made and, as far as I know, have failed to show it by his method. In my own case I have never been able to see it in sputum or tuberculous tissue when stained on this plan. Dr. Ehrlich's method threw more light on the subject, but his process is in many cases unsatisfactory. He, however, gave the clue to what was wanted in Koch's process. The anilin colours used will not stain the tubercle bacillus without the addition of another base in the shape of pure anilin, and the manner in which Dr. Ehrlich does this is open to objection and may account for his process not always succeeding. Pure anilin is sparingly soluble in water, and the amount taken up by the water will vary very much when his method is used.

The following process is one which will bring out the bacillus with ease and certainty, and in my hands has never failed. The colours used are magenta crystals and chrysoidin; the latter is a brown, which does not stain the ground substance so intensely as vesuvium. They can be procured from the Badesche Anilin Fabrik, 22, Bush-lane, Cannon-street, E.C. The following are the formulæ I have used: Two grammes of magenta crystals, three grammes of pure anilin, twenty cubic centimetres of alcohol, specific gravity 830, twenty cubic centimetres of distilled water. Dissolve the anilin in the spirit and then rub up the colour with it in a glass mortar, adding the spirit gradually until it is all dissolved, then add the water slowly, while stirring, and keep in a stoppered bottle. Make a saturated solution of chrysoidin in distilled water and add a crystal of thymol to make it keep; a dilute solution of nitric acid (Coml) is made, one part of acid to two of distilled water. For sputum the following process is the most simple. Spread a thin layer on a cover glass and let it dry, when quite dry pass it two or three times through the flame of a small Bunsen burner and let it cool. Filter two or three drops of magenta solution in a watch glass, place the cover glass with the sputum downwards on the stain, taking care there are no air bubbles under it. Let it remain for fifteen or twenty minutes, then wash in the dilute acid until all colour has disappeared, remove the acid with distilled water, when a faint colour will return; then place the cover glass in the same manner as before on a few drops of chrysoidin filtered into the bottom of a watch glass, and let it remain a few minutes until it has taken on the brown stain; wash off the superfluous colour in distilled water and place the cover glass in absolute alcohol for a few minutes, remove and dry perfectly in the air, place a drop of Canada balsam solution on the cover glass and mount. It is better to use small glass funnels for filtering the stains, as they protect the fingers. Sections of hardened tissue are treated in the same manner with the necessary modifications. With regard to the powers required to examine these bacilli after they have been mounted by this process an ordinary  $\frac{1}{4}$  inch with daylight

will show them perfectly, and a  $\frac{1}{2}$  dry glass will show that they are rows of spherical bodies with the same illumination. Their diagnostic value of course remains to be settled; I can only say that in a number of my own cases and some sent me, where there has been undisputed evidence of phthisis, there I have found the bacilli. In others where the signs have been suspicious, but not positive, some have given the organism, others have not. The progress of these last cases will be closely watched. In a number of cases of chronic bronchitis and emphysema and other chronic diseases of the respiratory organs, I have entirely failed to find the bacillus. In every case where the sputum has shown the tubercle bacillus, other slides have been prepared and stained, to show the putrefactive bacilli, which exist in large numbers and in several varieties in the same sputum, but none of these are stained by the magenta process. I have also made a series of experiments to see whether the bacilli increased in the sputum by keeping, and after taking the mean of a number of given areas from the first to the tenth day of the same sputum, I find no increase of the tubercle bacilli; but on staining duplicates to bring out the putrefactive bacilli, I find them enormously increased, and still they are not stained by the magenta process.

### LATENT PLEURITIC EFFUSION; ASPIRATION; RAPID RECOVERY.

By FREDERICK S. PALMER, M.D., M.R.C.S.

R. G. M.—, aged eighteen years, a watchmaker's assistant, came to my house on the evening of Friday, Feb. 17th, 1882. Upon his arrival he appeared much exhausted, very anæmic, and I noticed that his breathing was extremely short.

The patient gave the following account of himself. On Saturday, Feb. 4th (thirteen days previously), he played in a football match, when, in addition to rather rough treatment, he experienced a chill from wet feet. Next day he was stiff and sore, felt alternately hot and cold, had a short dry cough, and complained of pain under the left breast. On the following day he was better, the pain and cough disappeared, and he resumed his employment. Since then his breathing had become gradually shorter, and his weakness increasing with the dyspnoea obliged him to give up his work on the day he applied to me for assistance.

Upon examination of his chest, I discovered well-marked signs of effusion into the left side. The notes recorded in my diary at the time are: Absolute dullness anteriorly in the left infra-mammary region, and in the infra-scapular and lower part of the inter-scapular regions posteriorly, together with entire absence of respiration, voice sounds, and vocal fremitus; slight bulging of intercostal spaces; movements of chest on the same side impaired; complete absence of cardiac sounds; heart pushed over to the right side, the apex-beat being felt to the right of the sternum; breath sounds on right side and upper part of left lung exaggerated; no evidence of tubercular mischief, nor any family history of phthisis. Temperature in axilla 100°; pulse 104; respiration 48.

With these unmistakable signs of latent effusion, I sent him home with directions to go to bed at once, to apply hot linseed poultices to the side, and prescribed some diaphoretic mixture with small doses of infusion of digitalis every four hours. When I saw him the next day the physical signs were the same. He had passed a restless night, perspired profusely, had several slight attacks of syncope, and vomited twice. His urine was scanty, high coloured, free from albumen, and gave a copious precipitate with the silver nitrate test. For several days following his temperature, pulse, and respiration were much the same. There was an entire absence of pain. He coughed only slightly at long intervals, and lay upon the affected side. The attacks of syncope were frequent, and always followed any attempt to sit upright. He vomited occasionally after taking nourishment, and suffered each night from profuse perspiration.

On Feb. 23rd, his temperature fell to 99°, and his pulse to 96. I put him upon drachm doses of syrup of iodide of iron three times a day, and painted his chest back and front

with equal parts of tincture and liniment of iodine. He also took a teaspoonful of cod-liver oil twice daily. This treatment was continued for three weeks, with marked improvement in his general health. The attacks of syncope and vomiting were less frequent. There was no history of any rigor, but his night sweats were constant and distressing. The effusion, however, remained practically the same. There was no diminution in the area of dullness. The respiratory murmurs, vocal vibration, and voice sounds were absent, and the apex beat continued to the sternal side of the right nipple. On March 16th I introduced a medium-sized aspirator needle into the sixth interspace in the mid-axillary line, and drew off two pints of pale, straw-coloured serum, rich in fibrine, which almost immediately coagulated. Just as I withdrew the last quantity, the piston of my exhausting syringe was rendered useless by the washer becoming detached, and I was compelled to remove the needle at once. Before leaving the house I had the satisfaction of observing the apex beat restored to its normal position. The lung came down directly, and the vesicular murmur was apparent in the infra-scapular region. He made an excellent recovery. Four days after aspiration he was able to sit up, and at the end of a fortnight left home on a visit to some relations in Essex. When I last saw him, May 20th, he looked the picture of health. The respiration was almost identical at both bases, the movements of the chest perfect, and he told me that he had gained a stone in weight since his illness.

*Remarks.*—Cases of latent pleurisy are by no means rare, and are familiar to every practitioner of medicine. In the one reported above there are, I think, several points of interest. Experience has taught me the value, nay more, the importance, of early aspiration in cases of extreme, or even moderate-sized, pleuritic effusions. It is chiefly due to the researches of Trousseau, following those of Schuch and Skoda of the Vienna school, that the removal of the fluid by artificial means is now regarded as a wise and judicious proceeding, and averting the tendency to sudden death which occasionally happens in these cases. Dr. Roberts, in his Handbook of Medicine, gives his opinion that "ordinarily the fluid is best taken away by the aspirator; in exceptional cases the trocar must be used." This treatment is ably advocated by Dr. Bowditch, who recommends the introduction of the instrument immediately below the angle of the scapula. In three cases of extreme pleuritic effusion under my care during the last eighteen months, treated by early aspiration, the operation was followed by the happiest results. I was able to empty the chest, nor was any repetition of the proceeding required. Had it been possible to overcome sooner the objection of his parents to operative measures this poor boy would, in all probability, have been spared many weeks of suffering, confinement to bed, and saved much loss of time. The existence of a large amount of exudation arrests adhesion between the surfaces of the pulmonary and costal pleura, and by its pressure delays, or even prevents, absorption by hindering the circulation in the bloodvessels and lymphatics. "It must also be evident," as Niemeyer remarks, "that every additional day during which the lung is exposed to pressure, and the longer time allowed for cells to multiply in the exudation, so much the more are the chances of complete recovery diminished, and the danger of a fatal termination increased." The natural process of cure by absorption is uncertain, tedious (in large effusions extending sometimes over many months), and exposes the patient to chest deformity, anæmia, and its pernicious consequences, tuberculosis, syncope, and hypertrophy, with dilatation of the right heart. Early removal of the liquid by aspiration gives the compressed lung the chance of again becoming pervious to air, enables the displaced organs to regain their normal positions and prevents agglutination of the pulmonary alveoli. So far as my experience is concerned, it is an operation almost free from risk, and does not in any way interfere with the subsequent performance of paracentesis, if necessary. The inferences gathered from the case are that the ordinary therapeutical agents have little or no influence in promoting absorption in large pleuritic effusions. The continued existence of the exudation, although presumptive, is not *per se* conclusive evidence of the effused matter having undergone puriform degeneration. The absence of rigors correctly indicated the serous nature of the exudation. Lastly, that it is advisable to carefully examine the condition of the instrument and exhausting syringe before using it.

East Sheen, S.W.

## HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORBORENTI De Sed. et Caus. Morb., lib. iv. Proœmium.

### ST. THOMAS'S HOSPITAL.

#### STRANGULATED UMBILICAL HERNIA; OPERATION; RECOVERY.

(Under the care of Mr. SYDNEY JONES.)

C. C—, a female, aged fifty-two, married, was admitted into the hospital on March 3rd, suffering from symptoms of strangulated hernia, with the following history: For twenty years she had had a swelling at the umbilicus; it had never been quite reducible, but had at times been small and soft. She had worn no apparatus, as it caused her no inconvenience. She was quite well on going to bed on the evening of the 25th of February, but on waking next morning at seven o'clock, she was attacked with severe vomiting; between seven and ten A.M. she passed two loose motions, but there had been nothing passed after. From seven o'clock on March 1st until admission she had had constant sickness, and had been unable to keep down any food. At the same time she had had considerable pain in the abdomen and over the swelling.

On examination of the abdomen there was found an umbilical hernia, which the patient said was larger than usual; it was about the size of an orange, of an irregularly quadrangular shape, deeply congested, and with distinct impulse on coughing. She was a stout woman with a feeble compressible pulse, in a weak condition, and appeared to have considerable pain in the hernia at intervals; the tongue was furred, but moist. A little brandy was given, and an ice-bag was applied to the hernia. The patient vomited twice after admission; the second time the vomit was rather offensive, and as her general condition was worse and there was no local improvement, Mr. Sydney Jones decided to operate.

The operation was performed sixty-six hours and a half after the first symptom. Ether was administered and antiseptic precautions were taken. An incision was made in the middle line over the lower part of the swelling, and an attempt to divide the constricting part at the neck was made, but this failing, the sac was opened and found to contain a mass of deeply congested intestine, and a good deal of omentum. An incision in the lower part of the opening relieved the strangulation, the intestine was returned, and the omentum ligatured with catgut and removed. The edges of the wound were brought together with catgut sutures, and a drainage-tube was introduced.

Next morning she was looking much better. Pulse regular and of fair strength. No further sickness and no pain.

On March 5th the temperature in the evening went up to 101.8° without apparent cause. The urine was drawn off by catheter. On the 6th the urine was again drawn off. The wound was dressed, some sutures were removed, and strapping was applied. The wound looked well. On the 7th there was some diarrhoea, and this continued on and off until the 17th, when two enemata were given and a good deal of faecal matter came away. Opium had been given but had not checked it.

On the 14th the antiseptic dressing was discontinued and warm water dressing substituted. The wound was nearly healed. After the 17th she had no further trouble, and with the one exception mentioned above there was no rise of temperature throughout. She left cured on April 8th.

#### STRANGULATED CONGENITAL HERNIA IN A CHILD TWELVE MONTHS OLD.

C. B—, a boy, aged twelve months, was admitted on May 25th for a congenital hernia on the right side. The case was sent in by Mr. Verdon of Brixton. The child

had had severe vomiting for twenty-four hours. The hernia was very tense, and there seemed to be much thickening about the neck of the sac. Taxis was tried with a hot bath, and afterwards ice was laid over the rupture, a piece of flannel being interposed between the skin and the ice bag. After a few hours, the vomiting having continued severely and the child being pale and restless and evidently in much pain, chloroform was administered, and Mr. Sydney Jones dissected the parts down to the neck of the sac and divided the structures exterior to this, when the hernia was easily reduced. The edges of the wound were brought together by catgut sutures, and a small drainage-tube was inserted. Vomiting ceased after the operation and the child passed a motion. Next morning the child was quiet and looked better. On May 30th the child had some slight bronchial attack, but this soon passed off, and the child was presented well.

### VICTORIA HOSPITAL FOR CHILDREN.

#### A CASE OF ACUTE RHEUMATISM SIMULATING PYÆMIA.

(Under the care of Dr. RIDGE JONES.)

FOR the following notes we are indebted to Dr. George Weldon, registrar.

George S—, aged five years, was admitted on March 16th, 1882. Family history good. Patient never had rheumatism previously. About a month ago he was struck on the left side of the head by a stone, but no ill effects followed. On March 12th he was taken ill suddenly, with pain in the left side of the head and left eye, vomiting and diarrhoea, which lasted for two or three days, and pain in hands and toes; acute pain in left ear, but no discharge therefrom. There were a few spots on the arms and legs.—13th, 2 A.M.: Delirious; screaming and struggling; continued thus on and off until the 16th, the day of admission, when he slept a little. On admission the child seemed only partially conscious; temperature 102.6°; very restless. He experienced pain wherever touched; both elbows were swollen and fluctuating indistinctly; back of knuckles in a similar state; both ankles and all the metacarpophalangeal articulations swollen. All the joints appeared painful. Sterno-clavicular articulations enlarged and painful. Several petechial spots on limbs and body. Left eye: Deep vessels of conjunctiva injected. Iris clouded and discoloured. Pupil contracted; can only distinguish light and shadow with left eye. Tension diminished—2. Pulse 136, feeble.—18th: Rigidity of neck; less screaming, but a good deal of restlessness.—19th: Hands and joints of toes much swollen; rather quieter; head still retracted.—21st: Slept nearly all day.—25th: The heart's apex was one inch below and a little to the outer side of the nipple. The area of præcordial dulness was much increased. There was loud pericardial friction. The respiratory sounds were good.—29th: The temperature had risen to 104.8°, and there was much delirium.—30th: Temperature 102.4°; skin hot and dry; pulse 135, weak and thready; pericardial friction as before. The child did not now complain of pain. The bowels were open, and the tongue furred.

April 13th: The temperature has been fluctuating considerably, showing evening exacerbations and morning remissions. To-day acute pain in the head and abdomen came on. The pericardial friction has disappeared.—14th: Pain less.—22nd: Acute pain in the left eye, which is quite useless for vision. Tension—3. Atropine causes a very irregular dilatation of the pupil. Capsule of lens posteriorly coated with lymph, which obscures the retina from view.

May 1st: In a good deal of pain at night. Temperature 102°; pulse 135; tongue clean; vomits occasionally.—3rd: For about half an hour last night intense pain in the left eye.—6th: Chloroform administered. Mr. Cowell then removed the left eye. The sclerotic was found to be thickened, and the choroid also slightly. The capsule of the lens posteriorly was thickened and coated with firm lymph. Had little or no pain in the orbit after the removal of the eye, which seemed to give great relief. The temperature now showed some evening rise and morning remission for the next fortnight, when it became normal, and the child seemed cheerful, and, in fact, was convalescent, going out daily for

exercise in the grounds.—31st: The child suddenly to-day became worse, after being apparently well. Vomited four times in the night; slightly delirious; pulse weak; face pale.

June 1st: Continues the same. Vomiting without effort; cannot take food.—2nd: Fed per rectum; screams at night occasionally. The temperature is normal, and has remained so since May 17th. 4.30 P.M.: Convulsed down the left side; unconscious for about four minutes; breathing quiet.—3rd: Screaming about every three hours in the night; complaining of acute pain in the head; slept quietly in the intervals of the attacks. All day the screaming continued at intervals of two hours, and later on every hour. A regular epileptic fit at 3 P.M.; another between 5 and 6 P.M., commencing with screaming; squinted; in this fit for a quarter of an hour. Passed water during the fit, and came round at the finish with stertorous breathing. Another screaming fit at 7.45 P.M., with slight convulsions. Bowels acted during the fit. 8.20 P.M.: Died quietly, without any further convulsions.

*Necropsy.*—Pericardium adherent. Brain soft. Convolutions flattened. Both ventricles distended with fluid, about six ounces. No lymph or signs of inflammation about the optic nerve. No disease of mastoid cells.

#### ULCERATIVE ENDOCARDITIS SIMULATING PYÆMIA.

(Under the care of Dr. JULIAN EVANS.)

Louisa W.—aged thirteen, was admitted May 6th, 1882. History good. Has been treated previously at Brompton for heart disease. No distinct history of rheumatism previously. On May 2nd she was suddenly taken ill. Vomiting but no diarrhoea. Pain in chest and left leg. Left knee became painful and swollen. On admission loud systolic bruit at apex of the heart. Sound loud and clear over aortic valves. Behind, the systolic mitral bruit is heard. Slight presystolic bruit. Left knee-joint is extended by fluid and red, especially above and to the outer side of the patella. A small needle inserted and serum drawn off slightly cloudy. Other joints not red or painful.—7th: Ordered five grains of salicylate of soda every two hours, but stopped next day owing to much delirium and deafness during the night. Tongue brown.—9th: Pain in right knee.—10th: Passed a better night under the influence of opium. In great pain this morning. Delirious. Left knee less swollen, but pain in nearly all the joints, especially in knees, elbows, and ankles. Small joints of fingers not affected. Red patches and some vesicles and bullæ on hands and feet. Delirious during the night. Temperature 105°. Much injection of sclerotic vessels of left eye. Area of præcordial dullness much increased. Heart sounds loud and thumping. Friction sound chiefly with first sound. Respiratory sounds feeble.—11th: Much worse. Temperature 105.6°. Bullæ increasing in size and number, filled with serum, and pus around the margins. Left pupil dilated. Cornea and iris cloudy. Much chemosis of lower half of conjunctiva. Tension - 2. Tongue brown and furred. Much delirium. Ice bag applied and cold packing, but without materially reducing the temperature. Heart's area larger still. Some twitching of arms and resistance to extension. Some fluctuation in both knees, and slight redness over ankles.—12th: The temperature has fallen to 103°. Passed a better night under the influence of morphia; remains about the same in other respects.—13th: The temperature remained at 103° until 8 A.M., when death occurred.

*Necropsy.*—Dusky spots over body. Numerous bullæ, in size from that of a pin's head up to that of a shilling, on arms and legs. Heart: in left auricle a large vegetation about the size of a small raspberry; from upper surface of left auriculo-ventricular valve another growth, extending upwards, and just touching the former growth. Numerous inflammatory papillary granulations around, and fringing the free surface of the auriculo-ventricular valve, which is much thickened. Aortic valves thickened, irregular, and fringed with similar granulations. Right lung slightly bound down by adhesions; lung tissue fairly healthy, but slightly congested at bases; liver normal; spleen large, numerous infarcts scattered through it both old and recent; kidneys in same state as spleen; brain and meninges healthy. In both knee-joints a quantity of sero-pus, but no ulceration of cartilages or degeneration of synovial membrane. Both conjunctivæ were much injected and oedematous; both irides cloudy; vitreous of left eye thick and yellowish.

#### LIVERPOOL ROYAL INFIRMARY.

TUBERCULOSIS OF URINARY APPARATUS; SYMPTOMS  
SIMULATING VESICAL CALCULUS; MENINGITIS;  
DEATH; NECROPSY; REMARKS.

(Under the care of Mr. REGINALD HARRISON.)

FOR the following notes we are indebted to Mr. Ernest Barnes.

E. S.—, aged eleven, a schoolboy, was admitted on June 19th, 1882. About eight weeks before admission the patient after micturition passed some pus, which he described as being in little nodules. The symptom continued occasionally for twelve days. This was followed by the discharge of minute clots of blood at intervals after micturition. On admission, in addition to this history, he complained of micturating frequently with pain, afterwards referred to the penis and neck of the bladder. He was a fair delicate-looking boy, and for twelve months had often complained of headache. The urine was normal in appearance; sp. gr. 1010, acid; contained mucus and a trace of albumen.

June 20th: Mr. Harrison introduced a sound under ether, but no stone could be detected. Volkmann's bimanual method of examining the bladder was then employed, when a nodule at the fundus was distinctly felt. In the evening the temperature rose to 102°, falling in the morning to 97°. The patient was placed on a milk diet, and kept in bed. The evening rise in temperature continued.—24th: It was noted that he was slightly delirious during the night. Cold applications to the head were employed.—26th: Had a very restless night. In the morning he passed into a semi-conscious state, with strabismus and other symptoms of acute tubercular meningitis.—On the 27th he remained in much the same state of semi-unconsciousness. Some urine that he passed was found to be of sp. gr. 1020, acid, one-sixth albuminous.—30th: Died, having been quite unconscious for some hours.

*Necropsy.*—Lungs contained recent miliary tubercles. Liver was normal in size, also containing tubercles. The right kidney was healthy, ureter dilated; the left was enlarged, and, on section, the pelvis and calyces were dilated, and contained a yellow strumous membrane. This yellow, almost puriform, membrane extended along the whole length of the dilated left ureter to the bladder. There were tubercles in the substance of the kidneys, and some of the pyramids were partly absorbed. Bladder: the mucous membrane was covered with a multitude of minute superficial ulcerations, not apparently of a tuberculous kind; the mucous membrane of the trigone was roughened; at the apex of urachus a caseous tubercular nodule was formed which had been felt during life. Brain: convolutions flattened, lymph at base, ventricles very much dilated; recent miliary tubercles were found in both Sylvian fissures.

*Remarks.*—Mr. Harrison observed that there were points of special interest in this case, which was a good illustration of what might be seen in a class of disorders to which the term "urinary phthisis" had been applied. He had seen a good many instances of it in hospital practice, the patients being usually sent there on the suspicion that they were suffering from stone. The symptoms of urinary tuberculosis so closely resembled those of stone that an examination of the bladder with the sound was unavoidable. Under all circumstances it was necessary that such an examination should be conducted with the greatest gentleness and delicacy. Though the symptoms which followed made their appearance during the third day after the sounding, he felt sure that the latter proceeding was in no way responsible for arousing them. The patient was under ether and felt no pain either during or after the passing of the instrument. Whilst the patient was under the anæsthetic the value of Volkmann's method of examining the bladder with the finger or fingers of one hand in the rectum and the other hand above the pubes was demonstrated. The tubercular nodule in the fundus of the bladder was distinctly felt. In the diagnosis of growths and deposits in the bladder other than stone, Mr. Harrison had on several occasions demonstrated its assistance. Lastly, in the diagnosis of urinary tuberculosis attention was directed to the great value of careful and continued thermometric observation. In the irritability which accompanies stone in the bladder and tumours, an evening rise in temperature is only met with under very exceptional

circumstances—it cannot be said to be symptomatic of these affections—whilst in urinary tuberculosis it is constantly observed, and is to be regarded as an objective symptom of importance. Though in these cases the evidence afforded by an examination of the bladder with the sound is valuable, it would be quite possible to arrive at a conclusion by the other means of observation to which reference has been made.

## Reviews and Notices of Books.

*Physiologie des Muscles et des Nerfs.* Par CHARLES RICHEL. Avec 100 Figures. Paris: Germer Baillière et Cie.

IN this series of twenty-four lectures the reader must not expect to find a complete treatise on the physiology of muscle and nerve, for although many parts of the large subject of which it treats are considered at great length, others—such, for example, as the flow of blood through muscle during and in the intervals of contraction—are almost entirely neglected. In fact, M. Richet tells us himself that he was inclined to designate his work *Lectures on Irritability*. Throughout their whole extent he seeks to show that the laws of excitability are alike for nerve and muscle, and that there is little to distinguish the wave of undulation that accompanies muscular contraction from that which traverses the nerve-cell when stimulated or the nerve-fibre when it is the means for conducting a stimulus.

M. Richet commences, as might be expected, with an account of the movements of the cell. He gives, as a definition of irritability, “the reaction of the being to the external forces acting on it,” a definition not very dissimilar to that of life given by Herbert Spencer.

M. Richet proceeds to describe the effects produced on excitability by various stimuli, as thermic, mechanical, chemical, and electric agents, constructing curves which represent them graphically. He gives the following as a *résumé* of the conditions of cellular irritability. Oxygen is necessary, since that gas is consumed throughout the life of the cell. The vigour of the movements augments with the increase of temperature from 0° to 40° C., but after 40° C. the movements cease. Neutral and feeble alkaline solutions are favourable, acid are fatal, to them. Every change of state is an irritant to a cell, and consequently provokes its contractility. This change of state must be sudden; if slow, it does not provoke any reaction. Reaction to excitation is not sudden, but there is a period of latent excitation, a period which diminishes in proportion as the intensity of the excitability increases. Excitations so feeble as to be without effect when isolated, become effective when repeated at short intervals. A very short excitation provokes a prolonged movement. M. Richet coincides with Sewell in believing that the latent period in the contraction of muscle is very short; if it exist at all, it probably does not at most exceed 0.002 second. He gives the graphic tracings of the muscle curve from Marey, and shows the effects of weighting and of successive shocks with different intervals. He divides the relaxation consecutive upon contraction into two periods—a primary period, which is quick and sudden, and a secondary one, which is much slower. The latter he proposes to term *contracture*, which we think is to be regretted, since the word has already an accepted signification in surgery and pathology. In regard to this muscular contraction, he considers it to be a transient modification of the elastic tissue of muscular tissue; it is only observable in muscles that have few motor nerves, or in muscles the motor nerves of which are exhausted. It is a matter of regret that we have no term in English synonymous with *secousse*, which means the shock of a single muscular contraction; but gynaecologists will be interested to learn that the contraction of the uterus in labour-pains is not of the nature of a tetanic contraction or fusion of many contractions into one, but is a single long

contraction, lasting on an average 106 seconds. In regard to the effects of stimuli it is shown that when very feeble they may fail to cause contraction in a muscle, but that they nevertheless have a cumulative action, so that contraction occurs after the application of five or six stimuli, which would individually have been without effect; good tracings of this are given. M. Richet gives a table of the number of excitations required to produce tetanus, which shows that it varies greatly in different instances, amounting to 300 per second for the insect, 100 for the bird, 40 for the striated and 2 for the unstriated muscles of man, and 3 per second in the tortoise, whilst in the snail one excitation in ten seconds will produce tetanus. He gives as the result of his own researches the duration of the excitability of muscle, when no longer irritated by a current of oxygenated blood, and finds it to be one minute for the caudal muscle of the lobster, twelve minutes for the gastrocnemius of the frog in summer, forty minutes for the tortoise, five minutes for the dog, and one hour for the snail. But he acknowledges that great differences exist in the physiological states of the muscle which may in turn modify the duration of their excitability; in one instance, for example, the flexor muscles of the foot of the dog were excited for two hours at the rate of twenty induction shocks per second without being exhausted, so that it had received no less than 100,000 shocks.

We turned with some interest to see what M. Richet had to say in regard to the first sound of the heart, but he is too wary to make any positive assertion. The admission of a muscular sound as an element of the systolic bruit is, he says, in contradiction to the hypothesis that the cardiac contraction is a simple shock; but we do not know enough of the internal mechanism of contraction to conclude that the cardiac systole results from the fusion of several elementary shocks. On the other hand, it may be true that the shock occasioned by a single electrical excitation is composed of several smaller vibrations. On the whole, the question is left an open one.

A chapter is devoted to the elasticity, absolute force, and work of muscle. Tonicity, the author considers, may be only a modification of muscular elasticity, but this elasticity is subject to the control of the nervous system; and in support of this he points out that if the motor nerve of a muscle be cut the muscle relaxes, but it only relaxes if stretched by a weight. The relaxation, therefore, he maintains, is only a diminution in the elastic force of the muscle, or an augmentation of the extensibility. Speaking of the chemical constitution of muscle, he finds that, operating with 60 kilos. or 125 lb. of muscle, he was able to obtain 30 grammes, or about 0.5 per cent., of sarcolactic acid. The chemical and other phenomena accompanying muscular contraction are very fully given, and there is a short exposition of the pathological physiology of muscle.

The second half of the volume is occupied with the consideration of the physiology of the nerves, but we have no space to comment upon it.

The value of the work to a large number of readers will probably consist in the references it contains to other works, and the very clear summary of recent papers that it presents.

*The Journal of Anatomy and Physiology.* Conducted by Professors HUMPHRY, TURNER, and M'KENDRICK. Vol. XVI., Part IV. July, 1882. London: Macmillan and Co.

THIS part completes the sixteenth volume of this valuable and well-sustained journal. It contains six original articles: 1. Observations in Comparative Myology, by Hans Gadov, in which he discusses the question of the naming of muscles according to a uniform morphological principle; he then endeavours to illustrate the changes which the muscles of the vertebrata may undergo; and lastly, he describes the arrangement of the muscles of the hind limb, and traces

their homologies through the Amphibia and Sauropsida to man. 2. Fat Embolism, by Robert Saundby and Gilbert Barling, who append several cases which have come to their knowledge. 3. Micrococcus-poisoning, by Alex. Ogston. This observer, referring to recent writings, asks, Is it difficult to believe that micrococcus can be injurious or innocent just as it is allowed to grow under suitable or unsuitable conditions of culture or soil? His conviction is that the common micrococci which exist around, on, and in the human intestines, and which are resisted in their attempts at entrance by healthy individuals, but sometimes enter under conditions of lessened vitality, are one and the same with the virulent cocci which cause inflammation; that the difference is only that the production of acute inflammation shows they have found a suitable soil, a weak spot, or a weak individual, where they are cultivated in a mode calculated to elicit their virulent qualities. This paper is a very interesting one. 4. The Action of Saline Cathartics, by Matthew Hay. This article deals chiefly with the action of sodium sulphate. 5. A variety of Pulmonary Lobation, and its relations to the Thoracic Parietes, as illustrated by Comparative Anatomy and Abnormalities in the Human Subject, by William Allen. 6. Critical remarks on Polydactyly as Atavism, by C. Gegenbaur.

*The Illustrated Quarterly Journal of Medicine and Surgery.*  
Edited by GEORGE H. FOX and FRED. R. STURGIS.  
Vol. I, Nos. I. and II. New York: E. B. Treat.  
London: J. and A. Churchill.

THE first two numbers of a new American illustrated journal are before us. Each consists of twenty-four quarto pages of text, illustrated with wood engravings, and of four quarto coloured plates. The editors are promised the help of some of the most esteemed members of our profession in America. The illustrations are well done, and are abundant even to profusion, numbering twenty-one and twenty-eight respectively in these two parts. The cases have been well chosen, and care has evidently been taken to have a fair variety in each number. If the editors are able to make as good a selection of cases in the future, and can successfully resist applications to publish unimportant communications which happen to be well illustrated, we anticipate that this will be a popular and useful publication.

## New Inventions.

### JARVIS'S WIRE ÉCRASEUR MODIFIED BY JEFFERSON BETTMAN, M.D.

THIS is a modification of the Jarvis snare, shown at the International Medical Congress. It was devised specially for the removal of nasal polypi and hypertrophic tissue covering the turbinated bones. Its action is simple and efficient, and when properly used it should occasion but little pain and loss of blood. In the original instrument the sliding or outer cannula was propelled by a milled nut or

wheel, which has now been replaced by a flattened bar; this, for mechanical reasons, entails less expenditure of force and can be manipulated with greater ease and comfort. One of the chief points in the modified écraseur consists in the clamp screw to fasten the free ends of the wire loop. In Jarvis's instrument these were wound around small retention pins, and, if the case required, had to be undone and rewound. This is obviated in the modification; a simple turn of the screw releasing or clamping the wire.

Another point hereby gained is the impossibility of a fracture, the wire, except at its looped extremity, remaining straight throughout its entire length. The straight tube, which is used for operations in the nasal cavity, can be unscrewed from the handle and replaced by a long tube with the post-nasal curve, so that tumours or redundant tissue, growing from the posterior nares or in the naso-pharyngeal space, can be operated upon through the mouth. The wire used is the same as has been already recommended by Voltolini (*Anwendung der Galvano-caustik*, Wien, 1872, s. 251)—i.e., annealed steel pianoforte strings, Nos. 5 or 6. The instrument is made by Messrs. Mayer and Meltzer.

### AN ANTISEPTIC TROCAR CONVERTIBLE INTO A PROBE-POINTED KNIFE.

MESSRS. ARNOLD AND SONS have made for Dr. Ward Cousins a modification of the antiseptic trocar described in *THE LANCET*, Nov. 26th, 1881. After, by means of the trocar, the existence of fluid has been determined, the inner

tube of the instrument can be removed, and a probe-pointed knife, which fits exactly, can be passed along it, and is made so as to leave a cutting edge of one inch and a quarter in length. The direction of the edge of the knife is shown by a mark on the handle. This instrument may prove useful in cases of deep-seated abscesses and empyema.

### ARTIFICIAL RESPIRATION IN PUERPERAL CONVULSIONS.

To the Editor of *THE LANCET*.

SIR,—While congratulating Mr. Millican on the result of his case, recorded in *THE LANCET* of July 22nd, I may mention that artificial respiration was used in a case of puerperal eclampsia which I saw with Dr. Lambert of this town on June the 12th, 1881. The patient, a primipara, aged twenty-one, was seized with a convulsion at midnight, and though she lost consciousness, which never returned and the convulsions recurred frequently during the night, her husband did not seek for medical aid till seven in the morning, supposing her condition to be the usual symptom of approaching labour. Notwithstanding the inhalation of chloroform and the hypodermic injection of morphia, the convulsions increased in frequency and intensity, and about one o'clock, as she was evidently sinking, and the foetal heart's sounds were becoming fainter and fainter, it was decided to remove the foetus with the forceps; but before this was attempted she had another convulsion, and when it had passed off she lay motionless, having ceased to breathe, and was apparently dead. Air was made to enter her lungs by the method of Silvester, and after a little time natural respiratory efforts returned, but as they frequently failed, artificial respiration had to be fallen back upon several times, till at half-past four she had a convulsion, in which she died, all restorative measures, including the hypodermic injection of sulphuric ether, proving useless. Artificial respiration undoubtedly prolonged her life for more than three hours, and gave time for the extraction of the foetus, which was, however, dead; but had the convulsions been caused by the nervous supply of the respiratory muscles being temporarily knocked off its balance by reflex irritation, the result might possibly have been as satisfactory as Mr. Millican's, but unfortunately the uræmic odour was very marked, and the small amount of smoky urine found in the bladder almost completely solidified when heated, showing the presence of the usual cause of true puerperal eclampsia.

I am, Sir, yours faithfully,

Sunderland, July 26th, 1882.

JAMES MURPHY, M.D.

# THE LANCET.

LONDON: SATURDAY, AUGUST 5, 1882.

THE Executive Committee have quickly followed up their report to the meeting of the Association for the Advancement of Medicine by Research, by the publication of a valuable "Memorandum of Facts and Considerations relating to the practice of Scientific Experiments on Living Animals, commonly called Vivisection." It was necessary that some such statement should be the first publication issued by the Society, and the admirable manner in which this Memorandum has been drawn up promises well for the future prosperity of the Association. Calm and clear in its statements, it is yet most cogent in its reasoning, and we confidently expect that it will be very useful as a temperate, well-reasoned expression of the truth. The question of the even further restriction of experimental research in physiology and pathology in this country is almost sure to arise in Parliament before long, and the opportunity should be seized to make known in the Legislature the real facts of the case, and to strengthen the hands of the Government in the wise administration of the existing Act.

The Memorandum starts with the assertion that the art of medicine "does not depend upon arbitrary dogmas, or upon the theories of one or another school; it depends upon accurate knowledge of the structure and functions of the body in health and disease, and of the effects of various agents upon it, applied in each case by the aid of bedside experience." Knowledge of physiology, pathology, and pharmacology depends entirely upon observation and experiment; and it is pointed out that, in spite of the difficulties of research into the natural laws of living beings, "it would be as reasonable to expect the institutes of medicine to advance without laboratories and experiments on animals, as to hope for progress in chemistry or physics by allowing only observation upon metals and gases and forbidding the performance of experiments." The experience of the whole profession in all parts of the civilised world supports this assertion, and those most busy with the practical duties of their calling are among the most keen in their appreciation of the efforts and results of the more purely scientific investigators. The moral consideration arising from the fact that some physiological and pathological experiments cause pain, and some even loss of animal life, is next dealt with; and the duty of making a comparison between the injury to a sentient creature and the probable benefit to mankind or to others of his own species is freely accepted. A classification of experiments clearly shows that it is only a small number of them which are attended with pain at all, and that of these the large majority entail pain of quite insignificant amount; as the prick of a hypodermic syringe, or more prolonged discomfort, which in no way approaches what in other relations is spoken of as torture. The medical profession has never been behind the age in its feeling for the sufferings either of humanity or of the animal creation, and although there are exceptions to this as to every rule, it is yet true that the charge of

wanton cruelty has never been established against any investigator of repute in this country. The latter part of this Memorandum states the objects of scientific experiments on living animals, and it ranges these under six heads, as follows: (1) To extend, correct, and define our knowledge of the functions of the living body; (2) to obtain direct and exact knowledge of the processes of disease; (3) to test various remedial measures directly; (4) to ascertain the means of checking contagion and preventing epidemic disease both in men and brutes; (5) for instruction, and (6) for the detection of poisons. Under the first four heads many examples of experiments upon living animals which have proved of great value for those special purposes are detailed, and it is clearly shown that the advantages which have been derived by the experimental method of research are experienced in every branch of our art, and that dumb animals have participated in them in no small proportion. If a more mercenary view should commend itself to some in this utilitarian age, they will find that the now much abused and misnamed "vivisection" has added not inconsiderably to the wealth of nations. While it is only fair that physiologists should be required to answer the question *Cui bono?* in reference to the experimental method as practised for long periods of time—and it is a demand they need not shrink from—it is entirely unfair to ask the question of an experimenter as applied to each experiment. It is enough that its object be the elucidation of truth, and he may be content to wait for the recognition of the practical value of any given portion of truth—of any natural fact—until knowledge has so advanced as to show its appropriate place in the order of nature. In reference to the question of demonstrations to students, while it is insisted that physiology, like other sciences, should be taught practically, if at all, it is pointed out that long before the passing of the present Act experiments involving pain to animals were by common consent excluded from all courses of Practical Physiology, at any rate in this country. We believe that it is no exaggeration to say that "the evidence is ample to show what no one conversant with the subject doubts that the great strides made in the practice of medicine during the last fifty years have been chiefly due to the exact scientific and experimental inquiries of this epoch." And this being so, "so long as scientific men exercise their responsibility in the humane spirit which has hitherto guided investigation in this country, they have a right to ask that no unnecessary obstacles should be placed in their way."

THE question of the Notification of Disease seems to be exciting considerable attention in Greenock, which happens to be one of the few towns in which such a system has been more or less in force for some years. In consequence of this fact, Dr. WALLACE, the medical officer of health, was requested, some months ago, to furnish a report of the working of the system for the guidance of the Select Committee of the House of Commons on Police and Sanitary Regulations. The Report is in favour of a system of notification by the medical practitioner. Hitherto the practice has been that of notification by the householder. It was originally proposed in the Police Bill of 1876 to require the medical practitioner to report to the sanitary inspector every case of infectious disease in his practice. For this report he was to receive

2s. 6d. In default of such report he was to be liable to a fine not exceeding 40s. This clause was altered out of deference to the opposition of medical men, who thought it would tend to impair the confidence placed in them by the public and defeat the object of the Bill. The responsibility of notifying was then thrown on the householder. Dr. WALLACE says that many medical men then expressed an inclination to help the working of the Act. But though he admits that "the more respectable" practitioners in the town have done what they could to help him, the tone with regard to the profession generally is one of complaint, and one which we cannot but regret he should feel called on to use. "Covert if not open hostility, he observes, has been shown by others." He says in this Report, addressed primarily to the Board of Supervision of Scotland, that some practitioners not only did not advise the householders to report, but failed to give any advice themselves about disinfection and other measures of protection. "In several instances, practitioners studiously avoided naming the disease, in order, apparently, that the householder might say that he did not know the patient was labouring under an infectious disease. Indeed, instances have occurred of the practitioner having refused to specify the disease even when asked by the householder who had suspected the real nature of it, and was willing to comply with the law," &c. Dr. WALLACE thinks that "many medical men, in many cases requiring removal to a hospital, believe that the duty of reporting is an arbitrary mode of depriving them of their means of livelihood," &c.

Notwithstanding Dr. WALLACE's complaints against many of the practitioners, he is able to offer a very strong proof of the advantages of even the imperfect notification he has received. A large number of the reports reach him from registrars in cases of death—805 out of 4423; a small number direct from medical men—106; a large number of cases are discovered by sanitary officers, and a large number by neighbours who begin to know and appreciate the law. Though the present system admits of no further development—there being no substantial increase in the number of Reports for the last two years—it has still wrought a considerable improvement in the public health. The average death-rate has fallen considerably, as well as the average annual percentage of deaths from diseases of the zymotic class, so that Greenock now has the lowest mortality among the large Scotch towns, instead of almost the highest. The reduction in some particular zymotic diseases is very striking, as shown, e.g., in two five-year periods, 1871-5 and 1876-80, respectively, from the following diseases: Small-pox 55.20, 28.13; measles 50, 28.20; scarlet fever 93.40, 12.20; typhus 29.80, 19.20. The mortality from scarlet fever used to be 4.64 per cent. of all deaths in twenty-two years; in the last five the mortality has been .89 per cent. Dr. WALLACE says the mortality of cases removed to hospitals as compared with those treated at home was in 1878-81 as follows, in whole numbers: Typhus 15, 23; enteric 11, 22; scarlet fever 5, 11; measles 3, 1.

It must be remembered that Dr. WALLACE's statement is an *ex parte* one so far as it is made from the standpoint of the medical officer of health. We cannot but think it would have been better to have taken his evidence direct before the Committee, and to have had in sharp succession

to it that of the practitioners in Greenock. *Audi alteram partem.* We are loth to believe that any considerable number of practitioners, rightly appealed to, would be found unwilling to facilitate such an object as the restriction and limitation of infectious disease. Dr. WALLACE thinks that no further results will be got out of the householders' notification. He gives a singular reason for preferring that the medical officer should be made responsible. The householder, he says, is apt, by the intimation of the diagnosis of infectious disease, to be thrown into confusion and distraction. But is the doctor a man of leisure, with nothing to do but write and send to sanitary inspectors reports of infectious disease? Certainly he is not. Our belief is that Dr. WALLACE and other medical officers of health will find valuable co-operators in the isolation of disease in medical men if they will give them credit for being willing to be such, and if they will not strive to put upon their shoulders legal duties which attach properly to householders and parents.

FROM the brief report of the meeting held at the Royal College of Physicians on the 27th ult., which appeared in our columns last week, it will have been seen that the Fellows passed a resolution to the effect that the system of extensively advertising medical works, and the custom of giving, whether for publication or not, laudatory certificates of medicinal and other preparations, and of medical and surgical appliances, is misleading to the public, derogatory to the dignity of the profession, and contrary to the traditions and resolutions of the Royal College of Physicians. The College is to be congratulated on the action it has taken in this matter. Medical authors we are sure will take care, if publishers insist on advertising works of which they have the copyright in the columns of the daily press, that at least in future the advertisements will be shorn of laudatory notices. It is a matter, however, of regret that a more decided expression of disapproval was not given with regard to advertising medical works in the lay press. As the resolution at present stands, it leaves this open to the conscience of individual Fellows. As regards the majority, there can be little doubt that the liberty will not be abused; still there are some who are well known to have peculiar views on the subject, and a stringent resolution might have had the effect of making them conform to the general practice. Undoubtedly the profession as a body views with growing suspicion those of its members who are continually sounding their own trumpets, whether the note takes the form of extensively advertising their own works, or connecting their names with every pharmaceutical preparation, aperient waters, patent foods, or medical and surgical appliances, or of signing bulletins for insertion in the public journals with regard to the health of some comparatively insignificant personage who may happen to have the gout or an attack of influenza; or of a more ingenious form, which has lately come into vogue, of publishing cases which appeal to the sympathy and the imagination of the public in the reports intended for general circulation on the part of special hospitals. At the present day no excuse can be admitted for these practices. Forty or fifty years ago it might have been urged that a professional man had few opportunities of making himself known except to the limited circle of his school and a few professional

friends. But such an excuse cannot be maintained at present. Since that time the Medical Societies have multiplied to a prodigious extent, so that it is not difficult for a man who has anything to show or say, worth showing or saying, to bring it directly under the notice of the profession. The same may be said of the medical press: not only have the old-established journals vastly extended their columns for the reception of original articles, but nearly every branch of the profession has its own journal in which matters of special interest may be discussed. With so many legitimate means at command of bringing himself into notice, a man must indeed be perverse, and even blind to his own interests, to seek for ephemeral public approbation at the risk of losing the substantial rewards that surely, if somewhat slowly, await those whose work has received the stamp of approval from their professional brethren.

IN our Local Government Department we give a summary of eight reports on certain sanitary districts in the county of Denbigh, the reports having been prepared with a view of facilitating a final decision as to whether the districts in question can best be served by being formed into a united district for the purposes of the appointment of a medical officer of health, or whether the existing arrangements, which are without uniformity, and which involve the appointment of thirteen health officers, all engaged in private practice, shall be maintained. Acting, we assume, under official instructions, the Local Government Board inspector for North Wales has made a statutory representation, such as is required under the Public Health Act, 1875, to the effect that such a combination of districts is desirable in the interest of the several contributory places concerned; his action in this matter having received the support of the St. Asaph Rural Sanitary Authority, who in 1873 expressed a desire to see some such combination brought about; and that of the Ruthin Rural Authority, who in 1875 passed a resolution, which they soon after rescinded, to the effect that a combined appointment of one officer of health for the several sanitary districts of the county of Denbigh would conduce to a more efficient system of sanitary administration.

The reports referred to raise the whole question as to whether it is desirable as a rule to employ medical officers of health, not engaged in private practice, to act for a combination of sanitary districts, or whether it is more advantageous to appoint medical practitioners having other duties to act as resident health officers over smaller areas. Very valid arguments may be brought forward in favour of both methods of appointment, and it is by no means easy to lay down a rule which shall be applicable to all districts alike. On the one hand, it is contended that in his own immediate district a medical man who is both health officer and engaged in actual practice has special facilities for hearing of cases of infectious disease, and for suggesting immediate remedy, that he must of necessity have constant opportunity of acquainting himself with the sanitary condition of the localities in which his work lies, and that his occupation limits him to a comparatively small area, where he can, as a rule, be found on any emergency when immediate action or advice is needed. On the other hand, it is held that a medical officer of health who is appointed for a

term of years over a district large enough to secure for him an income apart from private practice, occupies a position of independence such as is necessary to the proper performance of the duties of his office, that he is free from the risk of offending patients, that he can secure in his work the needful aid of medical practitioners in a way which no competing colleague could aspire to, and that he has the special inducement, together with the favourable opportunities, for making himself thoroughly conversant with the scientific and practical aspects of public health questions, and that he hence acquires an influence both with the public, and as regards his advice to sanitary authorities, which could not otherwise be expected.

Speaking generally, we cannot but feel that the more weighty arguments lie on the side of those who would require the officer of health to devote his whole time to his duties. Perhaps the most prominent objection to this plan has reference to the fact that in a wide district such an officer might not be found in moments of urgency. But as a matter of experience, these sudden emergencies do not often arise, and the possible delay in securing the attendance of the health officer on some such special occasion is not to be compared in importance with the hindrances due to the endless and daily recurring ties of active practice, which compel the ordinary medical practitioner constantly to postpone his visits as officer of health until they become practically useless for the matter immediately under consideration. Besides which, too much importance must not be attached to instantaneous advice given on these occasions of emergency, and which has for its object to deal with some impending mischief, such as an epidemic; for it is rarely that proper effect can at such a moment be given to the advice, and even if efficiently adopted, it is seldom to be compared in value with the continuous action which is undertaken on the advice of a competent and trusted health officer, and which steadily does away with the very conditions which would otherwise tend to favour the occurrence of the emergencies anticipated. Regarding the proposed Denbighshire combination from these several points of view, it is quite obvious that, with one or two exceptions, real progress in sanitary administration has been all but limited to the sanitary districts employing as medical officer of health the only officer out of the thirteen referred to who has been able to give a large portion of his time to the duties of that office, and who is specially referred to as having taken pains to acquaint himself fully with the principles of sanitary science. Other officers have been assiduous, but they have, as a rule, failed to induce their authorities to carry out the remedial measures suggested.

Hitherto the sanitary authorities concerned have been unable to arrive at any decision as to which sort of appointment they should make, and, judging from the account of their more recent deliberations, unanimity does not seem to be near at hand. The proposed district is not extensive to a fault, as some combined districts have been; it is almost surrounded by railways, giving reasonably easy access to most of its populous localities, and, in view of past experience in the sanitary administration of its several component parts, it certainly seems desirable to secure for the whole county that uniform advice on health requirements

which emanate from one skilled officer, and which has already led to good results in some three or four of the sanitary areas comprised within it.

## Annotations.

"Ne quid nimis."

### HOSPITAL SUNDAY.

It is very gratifying to us to notice the steady growth of the Hospital Sunday Fund. The effects of the commercial depression upon the natural growth are now passing away, and the collection of 1882 exceeds that of 1878 by nearly £10,000. The cash received to July 18th amounts to £34,424 12s. 2d. After paying £1380, the proportion set apart for the purchase of surgical appliances, and allowing sufficient for liabilities and current expenses, the amount available for distribution is £32,415 13s. 9d., which, thanks to the prompt action of the Council, is now being distributed among the needy hospitals and dispensaries of the metropolis. On the Saturday preceding the collection we were at some pains to illustrate what we called the starvation of our hospitals. We are glad to know that our facts and statements received attention in the pulpits of the metropolis on Hospital Sunday, and were found very useful as a basis for the appeals of clergymen and ministers, which resulted in a collection exceeding by about a couple of thousand pounds the collection of last year. We are not yet satisfied with the collection. It represents neither the wealth of London nor its religion, nor the amount and gravity of the disease which is carefully and skilfully attended to in hospitals and dispensaries. We are, nevertheless, grateful for the strides by which the collection seems to mount up to the £50,000 which we think it ought to reach, and we regard these strides as an indication of the growing interest of the people, at least of religious people, in the great problem and duty of mitigating human suffering. There is another serious reason for a steady and considerable increase in the amount of the collection—viz., the gradual increase of the number of institutions claiming to share in the benefit of the Fund. It was shown by Dr. Glover on Wednesday, at the meeting of the Council, that while the collection of this year exceeds that of 1880 by £4000, many of the best hospitals are getting less out of the larger collection than they got out of the smaller. This was true of no less than half of the hospitals. The explanation given by Mr. Thomson Hankey, and no doubt largely the right one, was that the number of institutions claiming to share was constantly increasing, being now 145 against 130 in 1880. The value of this collection is intrinsically great. Let anyone try to collect such a sum for any other purpose that is not occasional, and in its nature sensational and temporary, and he will find how impossible it would be to get such a consensus of benevolent effort, in which Jew and Gentile, Protestant and Catholic, vie with each other. But it is not so much the amount of the collection that is so valuable, as the wide area of popular sympathy and interest in which it takes its rise. Until the institution of Hospital Sunday, the maintenance of hospitals had been the special and almost exclusive care of the wealthy and aristocratic classes of society, who, to their credit, supported them well. It is far better, however, and altogether fitter, in these days, when wealth is more equally distributed, that all classes should share in the pleasure of supporting hospitals and dispensaries; and it is the great value of Hospital Sunday that it brings this pleasure and this duty directly before thousands of people who would otherwise not be so appealed to.

### BRIGHTON SEWERAGE.

It is in no hostile spirit that we publish the report of Mr. Bailey-Denton on the sewerage of Brighton. The views and suggestions he has made seem to us so important, that it is only fair to the authorities and rate-payers of Brighton to place them at their disposal while there is yet opportunity to make use of them in the way of practical reform. It is needless to point out that the judgment formed and expressed by Mr. Bailey-Denton is no more dictated by prejudice than our own strictures have been prompted by malice against the most conveniently placed and generally eligible of seaside resorts in which Londoners are personally interested. It is childish to treat the friendly remonstrances of professional critics as the outpourings of a spirit of envy or animosity. It is solely in the interests of public health and of the visitors to and residents in Brighton we have interposed. It is indispensable to the comfort of the metropolitan population that Brighton should be placed in a satisfactory condition as regards its sewerage. No other locality can well be substituted for it as a popular sojourn, considering its proximity to the metropolis, but at the same time it is manifest that unless perfectly notorious defects in the sewage disposal of the town and neighbourhood are removed, Brighton must, and will assuredly, be avoided, let the Corporation resent plain truth-speaking as vehemently as it may. If the authorities of Brighton are well advised they will take the report we now publish into very serious consideration, and, before expending large sums of money on works which besides being costly may prove ineffectual, endeavour to arrive at a sound conclusion as to what it is best to do, not only in the interests of the resident population, but of that large class of visitors who regard this particular watering-place as the one accessible and attractive resort.

### THE BRITISH MEDICAL ASSOCIATION.

THE meeting of the British Medical Association, which takes place at Worcester next week, under the presidency of Dr. W. Strange, is one of especial interest from the fact that it is the fiftieth anniversary of the Association, which is to be celebrated in the same city that saw its inauguration by Sir Charles Hastings. Doubtless many references will be made in the course of the week to the growth of this important Association from the small "provincial" body of 1832 to the present large and influential organization, with its numerous branches. The programme of the meeting contains promise of good scientific work. There are no fewer than eight sections—viz., Medicine, Surgery, Obstetric Medicine, Public Medicine, Anatomy and Physiology, Pathology, Ophthalmology, and Otology; and in almost all of them one or more special debates have been arranged upon subjects of particular interest. The session may be said to open on Tuesday afternoon, the 8th inst., with service in the cathedral and a sermon by the Dean of Worcester. In the evening, at the Assembly Rooms, Guildhall, the opening general meeting will take place, when the president's address will be delivered, the annual report of the Council presented, and other business transacted. Notices of motion of two resolutions affecting alteration in the by-laws have been given: one by Dr. Milner Fothergill, limiting the term of office of editor of the *Journal* to five years, but eligible for extension to a like period; and the other by Dr. Ward Cousins, to the effect that the President of the Association shall be *ex officio* member of the General and Finance Committee, and providing for the annual retirement of four of the elected members of that Committee, who shall remain ineligible for re-election for two years. This resolution will be seconded by Dr. Grigg, and as it has a rather important constitutional bearing, it is

likely to give rise to some discussion. On the morning of the 9th, after the second general meeting, the address in Medicine will be delivered by Dr. Wade of Birmingham. A luncheon will follow, to be given to 500 members, by the Worcester and Hereford Branch, after which a bust of Sir Charles Hastings will be presented to the Mayor and Corporation of Worcester. The Sections meet at 3 o'clock, and sit for two hours and a half, and in the evening there will be a special service in the cathedral, at which Haydn's "Creation" will be performed by the Philharmonic Society, assisted by members of the Worcester, Gloucester, and Hereford choirs. On Thursday, the 10th, at the third general meeting, the reports of committees will be presented, and the address in Surgery delivered by Dr. William Stokes, of Dublin. The annual dinner will take place the same evening. On Friday, the 11th, the sections will meet in the forenoon, and the concluding general meeting is to be held. A garden party will be given in the afternoon at Madresfield Court, Great Malvern, by the Lord-Lieutenant and the Countess Beauchamp, the proceedings terminating by a *sermo* given by the President and G. W. Hastings, Esq., M.P. Excursions to the Malvern Hills, the Wye, Stratford-on-Avon, and the Severn, have been planned for Saturday, the 12th.

#### ARMY MEDICAL SCHOOL.

THE forty-fourth term of the School ended on Wednesday, when fifteen surgeons on probation for the British Army, and eight for H.M. Indian Army, were declared qualified to exercise commissions in their respective services. The Military Commandant of Netley, Colonel Sir Charles Pearson, K.C.M.G., Colonel Farman, the Director-General of the Department of the Army, Sir Joseph Fayrer, K.C.S.I., the Professors of the Army Medical School, and the whole of the medical staff of the hospital, and other officers and gentlemen, were present. Surgeon-General Longmore, C.B., read the reports of the session addressed to the Director-General for transmission to the Secretaries of State for War and India, with the names of the successful competitors for the various prizes published in another column, as well as those who had won honourable mention by their zeal and attention to the special studies of the place. The Director-General then presented the prizes, and addressed the gentlemen about to leave the School to enter on their career in their respective services. Dr. Crawford expressed regret at the absence of Sir Ralph Thompson, K.C.B., Permanent Under-Secretary for War, who was to have represented the War Office on the occasion, but who was detained in London by the pressure of his official duties in connexion with the expedition to Egypt. The Director-General, in graceful and hearty terms, congratulated the prize winners on the honours they had gained, and congratulated them all on having passed successfully their final examinations. Dwelling on the responsible and arduous nature of the duties of army medical officers, the Director-General pressed on their attention the responsibilities of their position in regard not only to the State, but to the soldier who is thrown on their hands in his hour of need without appeal. With great earnestness Dr. Crawford urged them never to delegate to irresponsible assistants duties that should be performed by themselves. He expressed the high opinion he entertained of the great value to the State of the Army Medical School, and congratulated the gentlemen before him on having had the advantage, unknown to officers of his standing, of acquiring knowledge special to their calling under its professors. The Director-General concluded by wishing the young medical officers a useful and honourable career in their respective services. Sir Joseph Fayrer added a few words of congratulation, and the proceedings terminated. The company were entertained at

luncheon in the handsome mess-room of the medical staff. The visitors saw Netley to great advantage. The day was beautiful. The corridors of the hospital and the wards, under the skilful hands of Surgeon-Major Dobson, were gay with flowers, as were the parterres about the mess-house; and to add to the beauty of the scene the yachts of the Royal Southern Yacht Club, competing for the annual regatta prizes, twice passed the hospital under full sail.

#### "DOCTOR" AND "CHAPLAIN."

It is much to be regretted when doctor and chaplain of a public institution do not agree. Generally they do; but the state of amity which exists is probably, in a majority of instances, due to concessions made by the former. This is not right; and we are glad to see that, in one case at least, the medical superintendent of an infirmary has had the moral courage to make a stand, and that a board of guardians has shown excellent good sense in enforcing his authority. We yield place to none in respect for the official character and work of ministers of religion generally, and would not be supposed desirous, or even willing, to under-rate the value of the services they render to suffering and distressed humanity in hospitals and infirmaries; but it should be clearly understood that the ministrations of the chaplain must on no account be allowed to interfere with the functions of the doctor or his assistants, or with the patients' meals. We have known instances in which the chaplain of an infirmary has shown such bad taste as to obtrude his presence in the wards during the time of medical attendance. In such a case he should be required to leave and prohibited from returning. If he declines to retire he is not fit for his post, and ought to be removed—from the ward and from the chaplaincy. Again, we have known chaplains who have persisted in troubling the patients with their presence and functions at times when they ought to have been quietly enjoying their meals or repose. This, again, should be peremptorily interdicted. Medical men ought to show themselves equal to the emergency, and without needless discourtesy protect their own rights and those of their patients from overbearing or thoughtless interference.

#### MOUNTAINEERING AS EXERCISE.

MOUNTAINEERING is doubtless excellent exercise for the nervously strong and the muscular, but it is unfortunate that it should be the pastime of the very class of persons least well-fitted for its pursuit. Those who lead habitually intellectual and, to a large extent, sedentary lives, incur great peril of injury and accident when they resort to this arduous and altogether exceptional form of exercise in their annual holiday. They may be steady of nerve and clear-headed, strong of wind and limb; but the strain is too severe, and the overtaxed faculties of sense and power may, at any moment, give way suddenly, when life will be jeopardised or sacrificed. Members of our own profession need a word of caution in respect to the way they spend their hardly earned vacation. We do not think that, as a class, they are particularly addicted to the climbing of mountains, but there are some who forget that unaccustomed labour of any kind, although it may be performed impulsively and perhaps with seeming ease—because there is for the moment some reserve of force on hand—is not safe work. A breakdown must reasonably be expected, and it is not prudent to venture life or limb on the hazard. Mountaineering, like everything else, requires long and continuous practice to make it an exercise which can be reasonably reckoned as salutary and within the bounds of a sound discretion. It is too laborious, too exacting to the sense-organs, and too severely exhausting to all the powers of life and energy, to be undertaken

without more than a mere feeling of courage and power, which may be misleading. The mountaineer should be always in training, or he should only attempt such climbing as calls for no particular expenditure of nerve or muscle force, and involves no extraordinary risk.

### THE EGYPTIAN EXPEDITION.

PREPARATIONS for the medical services of the campaign in Egypt have been unremittingly pushed on by the War Office authorities during the past week. The equipment of the field hospitals and bearer companies has been collected at the Woolwich Arsenal, under the superintendence of the Brigade-Surgeon in charge and the quartermaster of the Army Hospital Corps; the non-commissioned officers and men detailed for each hospital and company have been mobilised at Aldershot, so that as soon as the Admiralty provide transport the remaining seven field hospitals can embark at a few hours' notice. Between eight and nine hundred men of the Army Hospital Corps are required for the expedition, and of these six hundred have already joined the depot at Aldershot. The Peninsular and Oriental Company have placed the steamship *Carthage* at the disposal of Government, and she has been selected as the principal hospital ship. She has been fitted out to carry two hundred and twenty sick and convalescents, and when full will proceed to one of the general hospitals at Cyprus or Gozo to discharge her invalids, and return to Egypt for a fresh instalment. Brigade Surgeon H. Fergusson has been selected for her medical charge, with a staff of medical officers, an officer of orderlies (Captain Joseph), and four nursing sisters. Every attention has been paid in fitting the hospital to the requirements of the sick; ice houses are provided; and she will be liberally supplied with medical and surgical stores. The *Carthage* sails on the 9th. The steamship *Courland* has been detailed by the Admiralty for an additional hospital ship, and will be fitted in a similar manner to the *Carthage*, though on a smaller scale. Deputy Surgeon-General J. Lamprey is under orders for Cyprus to supervise the medical arrangements of the island, which, as a base of operations, will have allotted to it a general hospital of four hundred beds. The steamships *Pelican* and *Marathon* have been selected by the Admiralty to take out the 1st Bearer Company, and Nos. 2 and 3 Field Hospitals, leaving Portsmouth on the 5th. The principal medical officer, Surgeon-General Hanbury, C.B., and his staff, proceed in the *Capella* from Liverpool on the 6th.

### CEREBRAL LOCALISATION.

IN the *Medical News* Dr. H. J. Berkley publishes an interesting case bearing upon the question of cerebral localisation. The patient was a gentleman, aged seventy-three, who had suffered for many years from mitral and aortic disease. About two years and a half before his death he was suddenly seized with a twitching of the left angle of the mouth, apparently limited to the zygomatic muscles; it was unattended with unconsciousness, or other symptom of cerebral disturbance, and continued unaltered to the time of his death. At the autopsy the cerebral membranes were healthy, the cerebral arteries were atheromatous to their smallest visible branches; no embolism or rupture was found. The convolutions were very intricate; "on the ascending frontal convolution of the right side, one and a half inches above the margin of the Sylvian fissure, in a location corresponding to the seventh centre of Ferrier, a nodule of calcareous degeneration was found of nearly circular shape, three-sixteenths of an inch from side to side, and of a corresponding diameter from above downwards. The depth was very slight, certainly not greater than half of the thickness of the cortical grey matter." The remainder

of the brain was healthy. Dr. Berkley suggests that the lesion was an arterial occlusion, probably embolic, which underwent calcification. The case is of very great value, as the lesion was of minimum size, was unaccompanied by any other cerebral lesions, and was the cause of distinct and well-defined motor disturbance.

### JAMAICA MEDICAL SERVICE.

WE have recently referred to the deplorable state of the Government Medical Service in Demerara. The facts in relation to the same service in the island of Jamaica are, if anything, still more disgraceful, and we feel bound to call attention to them, both to warn the younger members of the profession against accepting appointments in the service, and in the hope that our remarks may lead someone in authority to investigate the matter and attempt to correct the evil. There are forty-eight medical districts in the island, each of which has one medical officer appointed to it; the salaries range from £150 to £200, and one of the great grievances is that during leave of absence, even when this is necessitated by overwork and disease brought on by the climate, only half of this paltry pay is granted. There are also complaints as to personal injustice, favouritism, and irregular promotion—offences which perhaps more than any others cause ill feelings in the service. During the last thirteen years no fewer than sixty-nine men have passed out of the service. Of this number twenty-two have died, nine have been dismissed, and thirty-eight have resigned their appointments (nine of these resignations have been compulsory), while only four have been pensioned. Such a state of things calls for redress in the interest of the colony quite as much as in that of the medical profession. These colonial appointments offer certain temptations—we cannot call them attractions—to many young men, but the real prospect they offer is gloomy in the extreme—hard work ill required! Our earnest advice to those who may contemplate offering their services to this colony is that of *Punch* to those about to marry, "Don't!"

### DEATH CERTIFICATES AT GUY'S HOSPITAL.

THE recently completed inquest in Southwark on newly-born children whose mothers had been attended in child-bed by students at Guy's Hospital has probably served a useful purpose in once more calling attention to the unsatisfactory state of the law respecting the registration of uncertified causes of death. We have to thank the medical authorities at Guy's Hospital for having been the unwilling and unintentional cause of the ventilation of this old-standing defect of the law. It is difficult to account for the objectionable and highly injudicious practice of the medical staff at Guy's in giving medical certificates of the cause of death of infants they had not even seen, on the mere information of the students. The inquest does not appear to have elicited the real object of giving these certificates. It is possible that there may have been some local opposition to the employment of the students in maternity cases on account of their inability to give a legal certificate in case of the death of the infant. The inquest will probably have the effect of securing in future the attendance of a duly qualified and registered member of Guy's medical staff in all cases which take a serious turn either for the mother or the child. In maternity societies there is too frequently a tendency not to insist rigidly enough upon a precise report as to the fate or health of the child at the termination of each maternity case. The influence of a well-conducted maternity society upon infant mortality, and the great importance of thoroughly trustworthy statistics of infant mortality in the first few weeks of life, which these societies could and ought to furnish, are

far too often lost sight of. The present record of infant mortality of most maternity societies is simply worthless. The Registrar-General's letter to the coroner on the facts brought to light at the inquest, in which he avows his helplessness in the matter, is a simple statement of the present condition of registration law, and, as the coroner remarked, leaves us precisely where we were before. In the present unsatisfactory state of the law lies the whole gist of the matter. Although we have no satisfactory statistics on the subject, we know that a large number of maternity cases are solely attended by midwives. We know that but a very small proportion of midwives are certificated or really qualified, and also that at present there is no system for registering midwives. Now all the deaths of infants born alive in midwifery cases so attended must be registered, and can only be registered as uncertified, and without any satisfactory evidence of the cause of death. What is still more objectionable, these midwives have the power of certifying (in cases where no registered medical practitioner has been in attendance) the infants as still-born. The effect of this laxity of legislation upon early infant mortality, and its statistics, is fast becoming a burning question, which far outweighs in importance the local question of the due superintendence of midwifery cases attended by the students at Guy's Hospital.

#### THE "ASYLUM POPULATION" AND THE "INSANE."

THE two terms are not synonymous. Although every inmate of an asylum for lunatics must needs be "certified," it does not, by any means, follow that every member of the asylum population is insane. Some have recovered and are simply drifting on because no one is specially interested to get them out. Others may have been sent in under misapprehension as to the real nature of their cases, which are, perhaps, the results of some temporary physico-mental excitement. Again, there are many who never were, and never will be, anything more than a little "queer." We are glad to see that in certain parochial districts attention is beginning to be aroused to the policy of instituting a detailed inquiry as to the present condition of the many paupers who have from time to time been sent into the county asylum, and who are practically forgotten. By an investigation of this nature, in some unions at least, the rates might be sensibly reduced, and the enormous demands every now and again made for money to build colossal asylums would be rendered unnecessary.

#### TWO NEW ANTISEPTICS.

M. G. LE BON has just presented to the Academy of Sciences two new and very effective antiseptics, the glyceroborate of calcium and the glyceroborate of sodium. Both of these compounds have the advantages of being very soluble, destitute of odour, and free from all toxic action. When exposed to the air they both deliquesce with great rapidity, absorbing from the air an equivalent weight of moisture. Both alcohol and water dissolve twice their own weight of these salts. They are powerful antiseptic agents even in very dilute solution; the most effective in a therapeutic point of view appears to be the calcic salt. It is absolutely innocuous, and it can be applied in strong solution to so delicate an organ as the eye without bad results. In a hygienic sense both can be employed with advantage as disinfectants and as preservers of meat and other alimentary products. M. le Bon has transmitted meat simply coated with a varnish of the glyceroborate to La Plata, and it has arrived in a perfectly fresh and sound condition. He thinks both salts will prove very useful as antiseptics in Lister's mode of dressing wounds.

#### HOSPITAL SATURDAY.

THE position and claims of Hospital Saturday are well set forth in an address by Mr. Sampson Gamgee on the subject, delivered lately before the Birmingham Medical Institute. Mr. Gamgee shows the importance of engaging the interest of the working-classes in the anxieties and responsibilities of hospital administration. He recommends for this end the representation of these classes on hospital committees. In principle we are very much inclined to agree with Mr. Gamgee. We are persuaded that these classes have only to display in the metropolis the same energy in the cause of hospitals which they have displayed in Birmingham to secure a reasonable representation on hospital committees. Mr. Gamgee reckons that the contributions of the working-classes in Birmingham to hospitals have grown from *nil* up to something like £8000 a year, if we include registration fees, provident payments, &c.

#### URETHRAL DIVERTICULA IN THE FEMALE.

AT the recent annual meeting of the Maine Medical Association Dr. Gerrish related a case which had occasioned him considerable difficulty. He was called upon to catheterise a patient after a difficult labour. After prolonged and fruitless efforts to pass the catheter, which he thought was prevented by "spasm," he etherised the patient, but even then could not succeed. Another practitioner was then called in, who tried for half an hour without success. It was then discovered that the urethra made a rather sharp turn in its course, and that a diverticulum passed off from each side of it, one two inches, the other one inch in length. The woman had never had a catheter used before. Subsequently there was no difficulty in entering either diverticulum or the bladder at will. The report of the case leaves us to assume that these "diverticula" were not made during the hour's fruitless attempts at catheterism!

#### DANGEROUS DRUGS IN THE HOUSE.

WE have repeatedly protested against the use of powerful and even poisonous drugs by unprofessional persons. We must go further, and warn those of the public who may be within our reach of the danger of having dangerous drugs in their keeping. A recent case of death from chloroform taken to relieve the toothache points this moral very painfully. It is a most distressing thing to be unable to obtain relief promptly in the moment of agony; but certainly no one who is suffering severely is in a condition to be trusted with a dangerous drug. Better put the perilous remedy out of reach. It is a grave mistake to keep chloroform, opium, and chlorodyne in any house, even though they are kept under lock and key. In a moment of maddening pain a sufferer forgets everything but the fact that ease can be obtained by recourse to a particular drug, and takes it recklessly, it may be with a dire result.

#### THE RIBERI PRIZE.

Is there no Englishman who will try for the "Prix Ribéri?" The prize is 20,000 francs, or about £600, and will be given by the Academy of Medicine of Turin in 1886, for the best embryological researches advancing our knowledge of the anatomy, physiology, and pathology of man. The essay must be legibly written or printed in Italian, French, or Latin. It must be published subsequently to 1881, and two copies must be sent free of expense to the Academy. The Academy will preserve the original, but the author may have copies at his own expense. If the prize is given to a manuscript, it will have to be printed and duplicate copies sent to the Academy before the prize is awarded.

### THE FUNCTION OF THE INTESTINAL JUICE.

PROFESSOR DANA of New York has recently been experimenting on the function of the succus entericus. His mode of procedure was to open the abdomen of an etherised animal, to ligature each end of a loop of ileum one to two feet long, then wash out this loop of intestine, inject albumen, fat, or starch, return the intestine, close the wound in the abdominal wall, and examine the contents of the intestine after four or six hours. He found that the intestinal juice had the power of converting coagulated white of egg into peptone, and hydrated starch into sugar. He failed to get any evidence of its power of digesting fats.

### EXCISION OF THE TONGUE.

MR. CROLY, of Dublin, performs the following operation for cancer of the tongue, even when the disease is situated in the anterior portion of the organ. He first ligatures each lingual artery close to the hyoid bone, through a curved incision reaching from the symphysis down to the hyoid bone, and up and back to the angle of the jaw. Through these incisions he withdraws the tongue, as in Ragnoli's operation, and removes the requisite amount of it by the benzoline cantery. Lastly, he divides the gustatory nerve where it lies along the inner border of the jaw-bone.

DR. A. J. FULLER, of Bath, U.S., reports a case of ascites which was tapped no less than forty-three times within a period of one year and three-quarters. The total quantity of fluid removed at the several operations was 1420 pints. The patient, a married lady, aged sixty-five, died a fortnight after the last operation.

DR. GAILLARD THOMAS has, it is stated, consented to resume his occupancy of the chair of Gynecology at the College of Physicians and Surgeons, New York, with Dr. Charles S. Ward as chief clinical assistant.

THE Irish College of Physicians is about to make arrangements for granting certificates in Sanitary Science to licentiates of the College. The fee is fixed at five guineas, not returnable in case of rejection.

A TOMBSTONE has, we are informed, been placed in Walmer churchyard over the grave of the late Fleet Surgeon William Anderson, by subscription amongst the officers of the Royal Navy and Royal Marines.

DR. DAVID W. CHEEVER has been nominated to the Professorship of Surgery in the Harvard Medical School, rendered vacant by the resignation of Dr. Henry J. Bigelow.

AN outbreak of typhoid fever has occurred at Bangor, and is, we hear, being investigated by the medical department of the Local Government Board.

WE regret to hear that Dr. M'Ewen, J.P. for Chester, has been stricken with paralysis, and remains in a precarious condition.

MR. THOMAS COLLINS has been re-elected a representative on the General Medical Council for the Apothecaries' Hall of Ireland.

A PROJECT of law making vaccination compulsory has been rejected by the vote of the Swiss people.

MR. C. G. WHEELHOUSE will preside at a meeting of the Fellows of the College of Surgeons of England, to be held at the Guildhall, Worcester, on Wednesday next, to consider matters affecting the interests of the Fellows generally.

### REPORT ON THE

## BRIGHTON SEWERAGE.

By J. BAILEY-DENTON, C.E.

IN compliance with the request of the Editor of THE LANCET that I should examine the present condition of the sewerage system of Brighton with special reference to the ventilation of the sewers, I have visited that town, and having had the advantage of reading Sir Joseph Bazalgette's report of June 27th, as well as receiving certain explanations from Mr. Lockwood and his assistant Mr. Palmer, I beg to submit the following observations.

I should state, prefatorily, that in the year 1875 I was called in by the sanitary authority of Hove to advise on their general system of internal sewerage, which is so far connected with the Brighton system as to be dependent for discharge upon the same outfall sewer as that provided for Brighton, and which is known as "Sir John Hawkshaw's intercepting outfall sewer." It had been completed about eighteen months.

The investigation I then made led me to form a judgment on that important work which my recent examination has confirmed, and, as I believe that the evils pointed out in THE LANCET on behalf of the residents and visitors to Brighton are greatly due to the defects appertaining to this intercepting sewer and its influence upon the internal sewers of both Brighton and Hove, I think it right to cite an extract from a lecture I gave before the School of Military Engineering at Chatham in the year following my investigations at Hove. I then stated that Brighton might be taken as an illustration of the evils arising from the impounding of sewage in the main sewers of seaside places.

I stated that "a visitor standing on the cliff at the ebb of the tide may see the sewage pouring from the outlet and marking its own passage through the sea for a considerable distance; and if he takes a drive on the parade while the sewage is impounded, he may smell it, to his utter disgust. If an engineer desires to study what to avoid, and to see works which have been admirably carried out in themselves, he should visit the sewage-disposal works of Brighton." While the average death-rate "of healthy districts is 17 per 1000, that of Brighton frequently rises above 20" (first quarter of 1882, 29 per 1000); "and this excess is only to be explained by the character of its sewerage, the treatment of its sewage, and the overcrowding of dwellings; for the town possesses all the advantages due to a southern aspect, an open sea, and a wide reach of downs to shelter it from cold wind and to afford the means of healthful exercise."

The grounds upon which I formed the judgment thus expressed, and which my subsequent visits to Brighton have confirmed, may be stated to be as follows.

1. The daily water-supply of Brighton and Hove, reckoned at from twenty-eight to thirty gallons per head, may be taken to be approximately 4,000,000 gallons, and this represents pretty nearly the measure of the sewage-proper discharged from the internal sewers into the intercepting sewer in twenty-four hours, irrespective of the subsoil water, which finds its way into certain sewers from the surrounding ground.

2. The total capacity (power of storage) of the intercepting outfall sewer between the tidal flaps at the Portobello outlet and the uppermost end at Hove closely approximates

3,000,000 gallons, the present storm overflows only coming into action when the sewer is practically full.

2. Twice in twenty-four hours—i.e., during the rise of each tide—the sewage of Brighton and Hove collects in this outfall sewer, and when such collection happens to take place during those hours of the day in which the water-supply is most largely used for domestic purposes, the quantity of sewage, diluted by subsoil water, is found to occupy as much as half the total storage space afforded by the sewer, leaving the remaining half as *air space*. In other words, the occupation of half the sewer by diluted sewage leaves room in the sewer for an equal quantity of surface waters (the rainfall), which, as they enter, will displace the air. The fact, which is striking, that during each tide in dry weather the diluted sewage collected in this sewer amounts to about 4,000,000 gallons, which is equal to the whole day's water-supply of Brighton and Hove, can only be explained by the leaky condition of the intercepting and, possibly, other sewers, which allows of the copious influx of subsoil water. Upon the only data I have been able to obtain in the time at command I am led to believe that the aggregate outflow from the intercepting sewer, without any increase due to the rainfall, may amount to at least three times the sewage proper, or above 12,000,000 gallons daily.

Sir Joseph Bazalgette says, in his report of June 27th:—"From the Steine to the outfall it (the intercepting sewer) is 7ft. in diameter, and it has an average fall of 3ft. in a mile, and this gives a mean velocity of flow of about  $1\frac{1}{2}$  mile per hour when running half full. But in dry weather the rising tide closes the outfall for thirteen hours out of twenty-four, and thus the lower portion of the sewer becomes a reservoir and stores the sewage until the tide has again fallen below its level. From the observations recently made and furnished to me by Mr. Lockwood, it appears that the ordinary dry weather flow of sewage rises during the time the outfall is closed to a maximum height of three to four feet above the sewer invert at the Roedean furnace, and it reaches the maximum there at about three hours after high water; the tide has by that time fallen below its level, and it again falls to its normal condition."

When I visited the Roedean furnace, on Tuesday, the 4th of July, I learnt from the man in charge that the depth of sewage in the sewer was 3ft. 8in.

4. The whole of the rainfall, I am informed, is admitted from the surface into the sewers, and the extent of impervious surfaces (roads, streets, roofs, yards, pavements, &c.) within Brighton and Hove, which may be taken as tributary to the intercepting outfall sewer, will probably amount to 1200 acres, and as it only requires about one-seventh of an inch of rain to fill the "air space," when the maximum quantity of diluted sewage is in possession of half the sewer, the times must be numerous when the force by which the sewer air is expelled and driven up the side sewers is sufficient to convey it into dwellings within its reach.

5. That this expulsion of air by the rushing in of surface waters does take place with great force is proved by the fact, I have heard stated, that the trapped gullies placed in the road gutters have been known to yield to the pressure, and afford the escaping gases a passage through the traps into the open atmosphere.

6. The number of public and private sewers joining the intercepting outfall sewers are much more numerous in Hove than in Brighton, and as there is a tendency in all sewer gases and organic vapours to collect in the higher portions of sewers, these lateral sewers become the outlets for more than their share of the foul air collected in the outfall sewer. This is made manifest by the circumstance that the Roedean furnace, which draws the sewer air in a direction contrary to its natural course, does not affect the outfall sewer much beyond the Steine.

7. The lateral sewers, up which the pent-up air for the most part escapes, having very rapid inclinations (rising in

fact in some instances with gradients of 1 foot in 12 feet), serve as shafts to ventilate the main outfall at the expense of the streets in which they exist and of those dwellings which may not have been perfectly disconnected from them. This assumption is based upon an experience which permits me to assert without fear of contradiction that there are few dwellings (which have not been specially treated with regard to internal sanitation) of which the traps in use will not yield to extra pressure, particularly where the heat, maintained within the houses themselves, exerts an inductive influence. I have reason to believe that the sanitary authorities of both Brighton and Hove require the private sewers connecting new houses with the public sewers to have inserted in them a syphon or a dip trap; but neither of these expedients without the admission of fresh air into the house sewer is sufficient to prevent the intrusion of sewer air under the conditions I have pointed out.

This exposition of facts, rather than opinions, will I trust serve to show that no amount of money expended in palliations such as those recommended by Sir Joseph Bazalgette will render the sewerage of Brighton what it ought to be. As a health resort Brighton is often frequented by invalids, who are especially sensitive of bad smells; and unless the sewers have a constant discharge, associated with a perfect system of sewer ventilation, the present evils will be maintained.

The facts stated, without any personal bias, afford evidence that THE LANCET was justified in declaring that the sewerage of Brighton and Hove was *radically defective*, in spite of the efforts made of late years to minimise existing evils which could not readily be removed.

I do not understand that it is either the duty or the intention of THE LANCET to point out how existing evils may be removed; how, in fact, a constant flow and discharge of the sewage may be effected, and the detention of foul matters to give off sewer gases avoided; how the separation of surface waters from the sewage may be secured; or how the sewers may be economically ventilated and the escape of deleterious gases and bad smells prevented.

In 1875-6, after advising at Hove, I stated publicly that "sooner or later there will be provided for the sewage of this important metropolitan watering-place (Brighton) a constant means of discharge by the application of steam power to raise and dispose of it above tidal influences"; and seeing that the present complaints are due to the conversion of an outfall sewer, which should act simply as a means of free discharge, into a reservoir of decomposing sewage and a container of effluvium and vapour extending along the leading thoroughfare from the extreme end of Kemp Town in Brighton to the extreme end of Cliftonville, in Hove, I can only, after my renewed examination, reiterate the conviction. I do so with increased earnestness, because the cost of lifting the sewage the necessary height to override the highest tide can be effected as a supplement to existing arrangements (after the partial separation of surface waters from the sewage) with comparative economy. If these two objects were carried out the question of ventilation would be simplified. Though the objectionable smells from manholes and gullies might still exist in places, all danger attending sewage decomposition would vanish, inasmuch as with a discharge at the outlet, independently of the tide, the rapid flow of the sewage, due to the rapid inclination of the internal sewers, there would be no detention nor any perceptible deposit in the outfall sewer. Such ventilation as would still be required might then be applied, without difficulty or any great expense, by the provision of shafts at the head of selected sewers, and by carrying pipes of sufficient size directly from such sewers to the top of houses. This might involve the purchase by the authority of certain houses for the purpose, without any great sacrifice of either money or appearance.

I think it only necessary to add that whilst concurring in much that Sir Joseph Bazalgette has advanced, I view with great misgiving his suggestion of a storm overflow at Roedean, to be constructed on a level with the invert of the intercepting outfall sewer, and additional storm outlets at Hove, as I am strongly of opinion that by the adoption of such a suggestion the advantage gained in freeing the shore of sewage pollution by extending the outfall sewer to Portobello would be lost to a great extent, and that the reputation of Brighton as a sea-bathing place would greatly suffer.

In a word, I would summarise what I have said by repeating that so long as Brighton remains with a tide-locked sewer extending along the whole length of its frontage to

receive surface water as well as sewage, without making an effort to prevent their detention, there will be cause for the strictures made by THE LANCET on the sewerage of Brighton.

22, Whitehall-place, London, S.W., July, 1882.

### WILLS AND BEQUESTS.

THE will of Mr. Edward Grestre, Surgeon-Major, half-pay, Coldstream Guards, of Torriano-villas, Broadstairs, Kent, who died on June 1st last, was proved on the 20th ult. by Mrs. Sarah Jane Grestre, the widow and sole executrix, the value of the personal estate exceeding £3500. The testator gives and appoints all his real and personal estate to his wife absolutely.

The will of Mr. Adam Taylor, Surgeon-Major, Bengal Military Service, formerly of 53, Warwick-road, Maida-hill, but late of Delhi, who died on October 21st last, was proved on the 22nd ult. by Mrs. Alice Johnston Taylor, the widow and acting executrix, the value of the personal estate exceeding £4300. The testator leaves £500 and all his furniture, plate, and household effects to his wife; and the residue of his real and personal estate upon trust for her for life, or until she shall marry again, and then for his issue as she shall by deed or will appoint.

The will of Tertius Ball, M.D., of 8, Bruce-grove, Tottenham, who died on the 2nd ult., was proved on the 25th ult. by the Rev. Charles Richard Ball, the brother and sole executor, the value of the personal estate being over £12,000. The testator gives to his wife, Mrs. Sophia Augusta Ball, in addition to some specific bequests, furniture and effects to the value of £250, a cash legacy of £450, and an annuity of £350; to his brother Charles Richard, his house in Bruce-grove; to his sisters Hannah Mary and Susan Helen, his freehold property in Shropshire and the residue of his real estate; and there are legacies, pecuniary and specific, to his own and his wife's relatives, servants, and others. The residue of the personalty he leaves to his brothers Alfred William and Charles Richard.

The will of Dr. Thomas Beville Peacock, Honorary Consulting Physician to St. Thomas's Hospital, late of 20, Finsbury-circus, who died at St. Thomas's Hospital on May 30th last, has been proved by Mrs. Maria Tucker, the sister, the value of the personal estate amounting to £18,000. The testator leaves all his medical books and surgical instruments and £100 to the City of London Hospital for Diseases of the Chest; and the residue of his property to his next of kin, according to the statute for the distribution of an intestate's effects.

The following legacies have recently been left to hospitals and other medical charities:—Mrs. Mary Sarah Burd, of 36, Connaught-square, Hyde-park, the residue of her personal estate, including the reversion to two sums of £5300 and £5800 Government stock, on the respective deaths of her sisters, Mrs. Clutterbuck and Mrs. Olive, to St. Mary's Hospital, Paddington, and St. George's Hospital, Hyde-park-corner. — Miss Elizabeth Baxter, formerly of Old Broad-street, but late of 309, Oxford-street, £1000 to St. Bartholomew's Hospital and £500 each to the Consumption Hospital, Brompton, and St. Mary's Hospital, Paddington.

### DISTRIBUTION OF THE HOSPITAL SUNDAY FUND.

A MEETING of the Council of the Hospital Sunday Fund was held at the Mansion-house on Wednesday. The Lord Mayor presided, and there were present, among others, Bishop Beckles, Alderman Sir Sydney H. Waterlow, M.P., Mr. Alderman M'Arthur, M.P., Sir E. H. Currie, Mr. Thomson Hanky, Rev. Canon Nisbet, Mr. Coope, M.P., Dr. Wakley, Dr. Glover, Mr. J. H. Buxton, Mr. R. Moreland, Mr. J. G. Piteira, Rev. Dr. Finch, Rev. A. A. Harland, Rev. R. S. Simpson, and Mr. H. N. Custance, the secretary. The committee of distribution submitted their report of the several awards they recommended for pay-

ment this year to 145 institutions, showing an increase of five since last year, and of forty since the establishment of the fund in 1873. Four per cent. of the total amount of the collections (£1390) was ordered to be set aside this year for the purchase of surgical appliances. The cash received to July 18th amounted to £34,424 12s. 2d. After payment of the sum of £1380 for surgical appliances, and allowing sufficiently for liabilities and for the usual current expenses, the amount available for distribution was £32,415 13s. 9d. Of that, £28,446 15s. was now recommended to 93 hospitals, including four institutions which may be classed as hospitals; and £2588 18s. 9d. to 52 dispensaries. They also recommended that all payments to the fund after that date be carried to the credit of next year's fund. In compliance with the order of the Council, and for the special use of its members, tables have been prepared as usual, showing a statistical analysis of the number of beds in hospitals, the cost of patients both in hospitals and at dispensaries, the proportionate expenses of management, as well as other valuable information. The committee had great satisfaction in reporting that the number of deputations invited to confer with them, and to offer explanations on matters of apparently unsatisfactory character, was gradually diminishing. Seven invitations were issued this year, as compared with eleven in 1881. Of that number three sent letters in reply, from two no answers were received, and two hospitals sent deputations.

Sir SYDNEY WATERLOW, M.P., in moving that the report of the Committee of Distribution be approved, and the several awards recommended be paid as soon as possible, congratulated the public that the result of the collection this year had been the receipt of the largest aggregate sum ever yet sent in. It was now nine years since the fund was started, and, like most enterprises, it had had its trials and difficulties, but they had all been amicably and successfully overcome. The greatest possible care had been taken to distribute the Fund according to the comparative needs and merits of the institutions; and he believed that not only the public, but even the managers of the hospitals themselves, had been satisfied with the awards. He added that it should be understood that the great endowed hospitals, such as St. Bartholomew's, Guy's, and St. Thomas's, did not participate in the Fund, but that the whole sum was distributed among institutions which for the most part were entirely dependent on the voluntary contributions of the public. The Fund, moreover, was collected and distributed at the very lowest percentage of cost.

Sir E. H. CURRIE seconded and Dr. GLOVER supported the motion, and it was adopted unanimously.

On the motion of the Rev. Dr. KENNEDY, seconded by Mr. COOPE, M.P., thanks were conveyed to the Committee of Distribution, and at the instance of Sir Sydney Waterlow, M.P., the Council thanked the Lord Mayor (Sir John Ellis) for the zeal and energy by which he, as president and treasurer, had succeeded in securing to the Fund the largest amount that had, as yet, been collected in any one year.

The LORD MAYOR acknowledged the compliment, and the meeting separated.

### NOTIFICATION OF INFECTIOUS DISEASES.

AT a meeting of the medical profession of Sheffield and the neighbourhood, held at Sheffield on August 1st, to consider Mr. Hastings' Bill relating to compulsory notification of infectious diseases, with Dr. de Bartolomé in the chair, and at which there were forty-one members of the profession present, the following resolutions were passed, with only three dissentients:—

1. "That this meeting views with entire disapprobation the proposal to compel medical men, without any discretionary power, to report cases of infectious disease to the sanitary authorities, feeling it to be an unwise interference with the relations in which medical men stand to their patients."

2. "That a petition embodying the views of the previous resolution be drawn up, signed, and presented through our members to the House of Commons and to the forthcoming meeting of the British Medical Association at Worcester; and that a deputation, consisting of the chairman, Mr. Favell, Dr. Keeling, Mr. Arthur Jackson, and Dr. Cleaver, wait upon the Mayor, to explain the views of the meeting."

An amendment, "That it is desirable, in the interests of

sanitary science, that Mr. Hastings' Bill become law," moved by Mr. Sykes, medical officer of health at Mexborough, found only three supporters, including the mover and seconder.

## Public Health and Poor Law.

### LOCAL GOVERNMENT DEPARTMENT.

#### REPORTS OF INSPECTORS TO THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

*Denbighshire Sanitary Districts.*—Under Section 286 of the Public Health Act, 1875, the Local Government Board have power, subject to certain specified conditions, to unite sanitary districts lying either wholly or partially in the same county for the purposes of the appointment of a medical officer of health, and early in 1881 the Board's resident inspector for North Wales made the necessary representation required under that section to the effect that such a union of a number of districts comprised in the county of Denbigh was desirable. But before an order giving effect to their intention was issued by the Local Government Board a deputation of the sanitary authorities concerned urged that such a course was most undesirable, and hence, before proceeding further, the board instructed their medical inspector, Dr. Parsons, to report to them on the sanitary condition and administration of the districts concerned. As the result of this inquiry eight reports have been issued. 1. *Holywell Rural District:* Formerly five district medical officers held the posts of medical officers of health, but later on the district was divided between two officers, and the reports which have been prepared by them have, for a series of years, shown that they had made themselves well acquainted with the sanitary condition of their districts; but the advice which was based on this knowledge appears to have had but little effect, for sanitary neglect, which was reported to the Local Government Board in 1871 by Mr. W. H. Power to be rife in the district, remained much the same in 1881. There has evidently been great lack of progress in sanitary administration, and this has certainly not been, even in the main, due to circumstances which could not be overcome. 2. *St. Asaph Rural District:* Here, also, five district medical officers were originally appointed to take sanitary charge of their respective districts, but in 1873 Dr. J. Lloyd-Roberts, of Denbigh, was appointed to the entire district. He is reported to have made himself acquainted not only with the sanitary circumstances of the district, but to have taken much pains to fit himself for his duties by making himself fully acquainted with the principles of sanitary science. The result has been a large amount of sanitary activity both in the execution of public works and in the abatement of conditions causing nuisance, such abatement being not merely temporary, but of a permanent character. 3. *Abergele and Pensarn Urban District:* Dr. Lloyd-Roberts is also medical officer of health for this district, which has been sewered and is provided with a constant service of water. Scavenging is irregular, and the waterclosets are not so ventilated as to free them from nuisance. These and similar defects have, however, been properly brought under the notice of the sanitary authority. By-laws relating to several matters are in force within the district. 4. *Denbigh Urban District:* This district was formerly under Dr. Lloyd-Roberts' care, but he resigned office in 1878, and was succeeded by Mr. G. Roberts. This district consists of Denbigh town and of Henllan village. It was inspected in 1877 by Dr. Thorne Thorne, who wrote a report strongly condemnatory of the sanitary neglect which the Town Council allowed to prevail. Since then, although certain grave defects remain, some substantial sanitary action has been taken in Denbigh town, but the Corporation still leave Henllan the subject of gross nuisances. By-laws are not enforced; the present medical officer of health admits that he does not make any systematic inspection of his district; and of Henllan Dr. Parsons says: "A more neglected place as regards sanitary condition I have never seen." The Denbigh Town Council cannot be congratulated on the proper exercise of their sanitary functions. 5. *Ruthin Rural District:* The sanitary authority for this district in 1875

represented to the Local Government Board that it would conduce to efficient health administration if the sanitary districts in the county of Denbigh were placed under one medical officer of health, but when the board proposed to act on the representation they rescinded their resolution, and strongly opposed action being based on it. They then made first one and then another appointment, apparently uncertain how to act, and recently a new officer has been elected for the entire district. No special sanitary work has been done in the district; but it appears to be a scattered locality, and its sanitary wants are not of a glaring and urgent description. 6. *Ruthin Urban District:* Dr. Lloyd-Roberts is officer of health for this district. A new and an abundant water-supply has been brought in, a system of sewerage has been carried out, house drains appear to be, as a rule, well constructed, by-laws are in operation as to removal of filth, pig-keeping is fairly well regulated, and the district is in the main subject to an efficient sanitary administration. 7. *Corwen Rural District:* This district has been divided into three portions for the purposes of the post of medical officer of health, two of the officers appointed being Poor-law medical officers. It is said that but little has been done towards the abatement of nuisances on private property; overcrowding of the worst description was ascertained to exist; many houses are without any privy accommodation; and conditions dangerous to health, when reported to the sanitary authority by their officers, are at times "left for consideration." Garth Trevor is evidently suffering much from such inaction. 8. *Llangollen Urban District:* Mr. J. P. Drinkwater has for some years had sanitary charge of this district, and his reports, though not deemed to be patterns, yet show that he has been active in the discharge of his official duties. The sanitary authority have yet many improvements to effect, but they have been by no means unmindful of their duties, and they are stated to be specially careful to curtail the spread of those infectious diseases which are liable to be imported into a district having picturesque scenery and a consequent inflow of excursionists. Since the issue of these eight reports meetings have been held as to the question of the health officer appointments, but from the reports which we have received there does not seem to be any immediate prospect of a satisfactory settlement of the difficulty being arrived at.

#### REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Huddersfield.*—We learn from Dr. J. S. Cameron's annual report for 1881, that the rate of mortality during the past year was the lowest on record since Huddersfield was incorporated in 1868; and this result is the more satisfactory because it has followed on a gradual diminution in the number of deaths during a series of years. The population in 1881 was 81,825, and the rate of mortality 20·3 per 1000. Amongst other sanitary advantages, Huddersfield possesses a hospital for infectious diseases, to which a new and excellently designed detached ward-building has recently been added, the need for extension having arisen together with an increasing appreciation on the part of the public of the advantage of isolation. For some five years past a system of compulsory notification of infectious diseases has also been in operation in the borough. At first, under an Act passed in 1876, medical men were required to give a written notice to the occupier, and this only when they regarded the accommodation as being inadequate for the treatment of infectious cases. The compulsory clauses in this form were not found to act satisfactorily, and hence, in 1880, fresh powers were sought by the Corporation, who still desired that the certificate filled in by the medical practitioner should be given by him to the occupier. But in Committee the clause was altered by the House of Lords so as to make the medical man responsible for the delivery of the certificate to the sanitary authority. Dr. Cameron regards the alteration as unfair towards the profession; but he explains that the plan has nevertheless worked well. Under the new clause all cases of infectious disease must be reported, irrespective of the means of isolation available; and Dr. Cameron has been informed by his medical colleagues that they find less difficulty in reporting now that the responsibility of deciding as to the quality of the accommodation no longer rests with them. The present system is stated to have "acted on the whole very smoothly," and not only are the certificates sent in with increasing promptitude, but, except in the case of "three or four" medical men, a number of optional ques-

tions at the foot of the notice are also answered. The effect has been greatly to extend the usefulness of the hospital for infectious diseases. From a table appended to the report we gather that out of 278 cases of small-pox, scarlet fever, and enteric fever which came under notice, all but 9 were duly certified under the Act, and as many as 164 cases were removed to hospital. The only disease in which any failure, as regards isolation, has occurred is scarlet fever, and the amount of accommodation available did not suffice for the isolation of all cases needing removal from their homes. This must for some years to come be expected in our large towns, where the poison of this disease lies hidden away in all portions of the districts concerned, ready to manifest itself directly a favourable occasion offers. But every case which is isolated will reduce the number of these hidden sources of infection, and the time may, we trust, soon come when even a reasonable number of beds provided by a sanitary authority will suffice for such isolation as is needed to protect the public against what may then be only occasional appearances of this now widely spread and fatal infection.

*Carlisle Urban District.*—In his report for 1881, Dr. Robert Elliot speaks generally as to the satisfactory sanitary condition of the city. He refers, however, to the fact that scarlet fever has for some time past been epidemic, 175 cases having been reported during the year. Out of 102 scarlet fever patients who remained in their own homes 29 died, whereas out of 73 who were removed to the city hospital for infectious diseases only 2 died. In view of this fact Dr. Elliot urges strongly that the compulsory notification of infectious diseases should become general, for under such a system alone can isolation on any comprehensive scale be carried out. The important work of providing for the efficient ventilation of the sewers is steadily in progress. In his efforts to secure this end Dr. Elliot has in the past met with much opposition from some who were evidently ignorant of the first principles relating to the subject. Now, however, the object for which he has contended is on the point of being attained, and we trust nothing will be allowed to frustrate its completion.

### VITAL STATISTICS.

#### HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns, 5652 births and 3176 deaths were registered during the week ending the 29th ult. The annual death-rate in these towns, which had been equal to 19.2 and 19.0 in the two preceding weeks, rose again last week to 19.6. The lowest rates in these towns last week were 13.2 in Cardiff, 13.3 in Portsmouth and in Brighton, 15.1 in Bradford, and 15.6 in Wolverhampton. The rates in the other towns ranged upwards to 24.4 in Newcastle-upon-Tyne, 25.2 in Leicester, 25.6 in Huddersfield, and 28.9 in Sunderland. The deaths referred to the principal zymotic diseases in the twenty-eight towns were 635, showing a further increase of 66 upon recent weekly numbers; 299 resulted from diarrhoea, 107 from whooping-cough, 84 from scarlet fever, 83 from measles, 46 from "fever" (principally enteric), 12 from diphtheria, and 4 from small-pox. The lowest death-rates from these diseases occurred in Halifax, Bristol, and Bolton, and the highest in Leicester and Huddersfield. Whooping-cough caused the highest death-rates in Liverpool and Sunderland; measles in Huddersfield; scarlet fever in Hull; and "fever" in Derby and Newcastle-upon-Tyne. The deaths referred to diarrhoea last week in the twenty-eight towns, though still considerably below the average for the season, showed a further increase upon recent weekly numbers; the highest death-rates from this disease were recorded in Leeds and Leicester. Only two fatal cases of small-pox were recorded in London and its outer ring of suburban districts, 1 in Birmingham, and 1 in Leeds. The number of small-pox patients in the metropolitan asylum hospitals, which had declined in the thirteen preceding weeks from 350 to 193, further fell to 159 on Saturday last; only 10 new cases of small-pox were admitted to these hospitals during last week, against 30, 23, and 20 in the three previous weeks. The deaths referred to diseases of the respiratory organs in London, which had been 199 and 157 in the two preceding weeks, rose again to 183 last week, but were 1 below the corrected average number in the corresponding week of the last ten years. The causes of 74, or 2.3 per cent., of the

deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Portsmouth, Plymouth, and three other towns; whereas the proportions of uncertified deaths were largest in Bristol, Leeds, Salford, and Hull.

#### HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which had been equal to 21.3 and 21.7 per 1000 in the two preceding weeks, declined again to 21.3 in the week ending the 29th ult.; it exceeded, however, by 1.7 the mean rate last week in the twenty-eight large English towns. The deaths referred to the principal zymotic diseases in these Scotch towns were 111 last week, and within 2 of the number returned in the previous week; they included 64 from diarrhoea, 16 from whooping-cough, 13 from "fever," 7 from measles, 6 from scarlet fever, 5 from diphtheria, and not one from small-pox. The death-rate from these principal zymotic diseases averaged 4.7 per 1000 in the eight towns, and exceeded by 0.8 the mean rate from the same diseases in the large English towns. The 64 fatal cases of diarrhoea showed a further increase upon recent weekly numbers, and exceeded by no fewer than 25 the number returned in the corresponding week of last year; 39 occurred in Glasgow, 7 in Edinburgh (Dr. Littlejohn, however, only attributes 3 deaths to this cause), and 5 both in Dundee and Paisley. The annual death-rate from diarrhoea in the Scotch towns was again last week very considerably higher than that which prevailed in the English towns. The 16 deaths from whooping-cough, which included 9 in Glasgow and 3 in Aberdeen, corresponded with the number in the previous week. The 7 fatal cases of measles showed a marked decline from recent weekly numbers, but included 4 more in Dundee, against 9 in the previous week. The deaths referred to "fever," which had been but 7 in each of the two previous weeks, rose to 13 last week, of which 6 occurred in Glasgow, and 2 each in Paisley and Perth. All the 5 fatal cases of diphtheria, and 3 of the 6 of scarlet fever, were returned in Glasgow. The deaths referred to acute diseases of the lungs in the eight towns, which had been 95 and 80 in the two previous weeks, were 82 last week, and exceeded by nine the number attributed to these diseases in the corresponding week of last year.

#### HEALTH OF DUBLIN.

The rate of mortality in Dublin, which in the two preceding weeks had been 21.9 and 20.8 per 1000, declined again to 20.8 in the week ending the 29th ult. During the first four weeks of the current quarter the death-rate in the city averaged 20.0 per 1000, against 18.0 in London and 18.6 in Edinburgh. The 139 deaths in Dublin last week were 7 less than those returned in the preceding week, and included 5 which were referred to diarrhoea, 3 to measles, 3 to "fever," 1 to whooping-cough, and not one either to small-pox, scarlet fever, or diphtheria. Thus 12 deaths resulted from these principal zymotic diseases, against 9 and 8 in the two previous weeks; these 12 deaths were equal to an annual rate of but 1.8 per 1000, against 3.9 in London and 2.5 in Edinburgh. The fatal cases of diarrhoea, which in the two preceding weeks had been 5 and 7, declined again to 5 last week, and were considerably below the average for the season. The 3 deaths from measles exceeded the number returned in recent weeks, and the three fatal cases of "fever" raised the number recorded in the first four weeks of the current quarter to 11. The death referred to whooping-cough was the first registered since the end of April last. The deaths both of infants and elderly persons showed a considerable increase upon those returned in recent weeks. The causes of 15 or nearly 11 per cent. of the deaths in the week were uncertified.

**A MEDICAL MISSIONARY FOR CENTRAL AFRICA.**—A farewell service was held at St. Thomas's, Regent-street, on Tuesday last, to bid God speed to Dr. James Petrie, who has been selected by the Guild of St. Luke as the medical missionary for Central Africa. Dr. Petrie received his medical education at Aberdeen University, where he graduated M.B., M.Ch., in July last. The salary of this medical missionary is provided by the Guild of St. Luke—viz., £200 a year for three years.

## THE SERVICES.

Surgeon Major de Faback, Bengal Army, has been appointed Sanitary Commissioner for Bengal, vice Surgeon Major Lidderdale.

Brigade Surgeon R. Wolseley succeeds Brigade Surgeon J. A. Marston as Secretary to Surgeon General Sir Anthony D. Home, V.C., K.C.B., Principal Medical Officer in India.

Deputy Surgeon General C. Smith, M.D., Madras Medical Service, has been appointed Principal Medical Officer of the Indian Contingent for service in Egypt.

Surgeon Major G. Macnalty has been appointed to the medical charge of the Station Hospital, Roorkee, N.W. Province, India, vice Surgeon Major Douglas, V.C., who is retiring from the service.

ARMY MEDICAL DEPARTMENT. — Director-General Sir William Muir Muir, M.D., K.C.B., has been granted a retired allowance, in addition to his good service pension; Surgeon Frederick Simon Young, half-pay, has been granted retired pay.

YEOMANRY CAVALRY. — Middlesex: Thomas William Thompson, Esq., late Surgeon, 1st Life Guards, to be Surgeon, vice J. S. Ferris, resigned.

RIFLE VOLUNTEERS. — 2nd Glamorgan: Acting Surgeon John Lindsay Leckie to be Surgeon. — 19th Lanarkshire (Liverpool Press Guard): James Booth Clarkson, Gent. (Medical Officer Inman Line), to be Lieutenant. — 1st Lincathgowshire: Robert Kirk, M.D., to be Acting Surgeon. — 2nd East Riding of Yorkshire: Acting Surgeon Charles Danson, M.D., resigns his appointment; Arthur Henry Bissier, Gent., to be Acting Surgeon.

ADMIRALTY. — Fleet Surgeon John Black Nicoll, M.D., has been placed on the retired list of his rank.

The following appointment has been made: Surgeon George Despard Twigg to Chatham Division of the Royal Marines, vice Charles C. Godding.

## Correspondence.

"*Andi alteram partem.*"

## "THE RIDER'S SPRAIN."

*To the Editor of THE LANCET.*

SIR,—The interesting communications from Mr. Morris and Dr. Henderson, in *THE LANCET* of July 29th, call the attention of surgeons to a very important, but not very common, kind of injury. It is doubtful whether the term "rider's sprain" could be applied to all these particular injuries. The following case might probably be classed under this heading; it was, however, clearly a case of complete rupture of the tendon of the adductor longus near its origin from the tubercle at the angle of the pubes.

W. C—, a gentleman aged forty-five years, was riding a young restive horse at the end of last year. The animal, being startled at something, plunged violently, causing the rider to grip the saddle suddenly and forcibly with his knees to prevent himself being unseated. He felt a violent pain at the upper and inner part of his right thigh; he was compelled to dismount at once and hobbled home with great difficulty. He was seen immediately by Dr. John Lloyd of Small Heath, who found a distinct depression, large enough to lay the thumb in, over the site of the tendon of the adductor longus muscle, with a contracted muscular belly below this sulcus. He diagnosed readily the nature of the injury, and applied a firm bandage from below upwards, with a spica about the groin. A few days afterwards a sharply defined triangular ecchymosis appeared, having its apex upwards at the pubes, and its base downwards and outwards, disappearing towards the middle of the thigh. After a few weeks' treatment the patient made a perfect recovery; a small swelling remained at the site of injury for many weeks.

The features presented in this case are quite in accordance with those known to be present in the other more frequently ruptured muscles—viz., the calf muscles, biceps humeri, and rectus femoris. It is noteworthy that all these muscles commonly yield at their rounded and tendinous portions—

thus: the calf muscles at the tendo Achillis; the biceps at its tendinous origin from the glenoid cavity; the quadriceps just above or below the patella; and the adductor longus near to the pubes.

I am, Sir, your obedient servant,

JORDAN LLOYD, M.B., F.R.C.S. Eng.,  
Casualty Surgeon to Queen's Hospital, Birmingham.  
Broad-street, Birmingham, July 31st, 1882.

*To the Editor of THE LANCET.*

SIR,—Rider's sprain, according to Mr. Morris and Dr. Henderson, seems a much more common accident in civil than in military life. I can only remember three cases of rupture of the adductor longus muscle during a period of sixteen years in a cavalry regiment—once in England, in the rough-riding sergeant-major; the other two cases occurred in India. I cannot remember a case occurring amongst men in robust health and riding hard. I therefore think that the accident is due to want of muscular tonicity, and from the muscle in that state being suddenly called into violent action by the horse plunging forward when the rider is sitting loosely in the saddle. I never met with a sprain of the pronator radii teres, and I am not satisfied with Mr. Morris's explanation that it is the back stroke, because I have seen a great deal of racquet playing, when the back stroke is constantly practised, and I never heard any complaint such as Mr. Morris describes as the lawn tennis arm. I should be more inclined to attribute the accident to the heavy tennis ball and bat, which latter is year by year becoming heavier, and naturally taxes severely all the muscles having their attachment or insertion in the radius, the heavy bat being at the end of a long lever.

There is another accident which was very common during the Badminton rap in India, and I have also seen it at home with lawn tennis—viz., acute pain of the external condyle of the humerus, with occasionally swelling and thickening of the bone. I attribute this accident to the head of the radius constantly jarring against the condyle during the game.

I remain, Sir, yours faithfully,

C. A. INNES, M.D.,  
Deputy Surgeon-General, H.P., A.M.D.,  
late Surgeon-Major, 16th Lancers.  
Hull, Aug. 1st, 1882.

## "VACCINATION IN SCOTLAND."

*To the Editor of THE LANCET.*

SIR,—In your annotations last week you refer to vaccination in Scotland, pointing out some defects which would be remedied by a partial adoption of the English system. 1st. You look upon the provision that "no child need be vaccinated until it is six months old" as a disadvantage in our system, whereas here we consider that as the chief reason why vaccination is with us so popular, and so little liable to be followed by bad results. It is well known that constitutional diseases, such as syphilis and ecthyma capitis, manifest themselves in the first three months of life, and these, if following vaccination, are popularly believed to be the result of that operation. If we wait until the fourth or fifth month we, in a great measure, escape these dangers, and are more certain to have uncontaminated lymph. 2nd. "Many escape until the age of nine to twelve months, on account of the want of a system of inspection." This indeed must be extremely rare when the registrars do their work faithfully, and in that they are well looked after by the periodical examiners. 3rd. "The absence of Government grants for special success is much felt." I have practised in Scotland now for several years, and have never once heard this complained of, but have often heard my professional brethren criticise severely such a system in England. It is rather a slur upon the profession generally to think that without some specially recognised reward they will not properly perform their duty. 4th. Ample provision is made for all those who are unable to pay the vaccination fee. 5th. "In truth the lymph in general use is thoroughly humanised." This again is a mistake. It may be in the hands of some, but in our district at least this is not general. 6th. "Effectual protection in the face of a virulent epidemic cannot be anticipated unless the vaccination is not only as regularly, but much more thoroughly, performed

than it is at present." In answer to this, I can only point out the freedom of Scotland from small-pox, and I should hardly think you would wish better proof of the success of our system.

I shall be glad if this letter will in any way assist in altering the views of the profession in England so that they may adopt the six months' limit instead of three, which I am sure would materially assist in stopping the continual prosecutions in England, and in rapidly increasing the popularity of the operation.

I remain, Sir, yours truly,  
Hawick, July 31st, 1882. JOHN R. HAMILTON, M.D.

## DRY AND INFREQUENT WOUND DRESSING.

To the Editor of THE LANCET.

SIR,—Dr. Edward Thompson's communication on Puffball and Dr. Lockhart Gibson's on Salicylic Silk for Wound Dressing, in your current number, suggest a few observations on the principles underlying the treatment. Those materials have the common character of being dry and absorbent, and, in the case of the salicylic silk, it is especially noticed that the dressing was renewed infrequently, sometimes not until the twelfth or fifteenth day.

The discussion on wound treatment has brought more and more into prominence the value of infrequent dressing, on which the majority of surgeons are now agreed. Dry dressing is also gaining largely in favour. The value of rest is universally conceded, and of position rarely questioned. Pressure is also, though more slowly, winning the place it merits in surgical therapeutics; and I venture to think the time is not far distant, when general assent will be given to the proposition which I have repeatedly had the privilege of sustaining in these columns: "The majority of wounds heal rapidly and painlessly under dry and infrequent dressing, uniform gentle pressure, and absolute rest."

I am, Sir, yours faithfully,  
Birmingham, July 31st, 1882. SAMPSON GANGE, M.D.

## "SANITARY STATE OF MARYPORT."

To the Editor of THE LANCET.

SIR,—Amongst your annotations in THE LANCET of July 22nd, I find one on "The Sanitary State of Maryport," casting certain reflections upon me as the sanitary medical officer, to which, in justice to myself, I feel called upon to make some observations; for I must tell you that the article is one series of misrepresentation from the beginning to the end. First, there was no typhus in April, 1881. In the next place, I never talked such nonsense as you have put between inverted commas. Neither was there one or two hundred cases of typhus; for though suffering from the effects of an accident, and unable to attend myself, I am satisfied that nearly all the typhus cases were attended by Dr. Little, and therefore known to me. Again, the sanitary authority has a right to send fever patients to the infirmary, which is not above a rag-store, but is above an old unused maling-room, the floor of which is made of concrete, therefore it is impossible for the effluvia from any store to enter the wards; neither can the sewage from the infirmary percolate into any stores. Such are the misstatements of which I think you will agree with me that I have a right to complain. I am not here about to enter upon the sanitary question of the town; for I have neither the time nor inclination at the present to do so; but I can say that it will compare in that respect with any town in Cumberland. That there is still a great deal to be done I know well; but in my opinion such sensational writing as is contained in your article has a very great tendency to do a very great deal more harm than good, and would not, therefore, have been noticed by me if it had not appeared in the pages of THE LANCET. To show you that I am no tyro in the profession I must tell you that for about thirty-six years I have been the medical officer of the Maryport District of the Cocker-mouth Union, with a population of some 16,000. During all that time I have advised not only the guardians, but the trustees also, as to the carrying out of the various Orders in Council long before there was any sanitary authority. Consequently, I have had to take a leading part in the care and

treatment of the sick through all the various epidemics which have invaded us during all those years. I need not tell you, then, that I claim some consideration for my opinion on the various subjects connected with sanitary matters, though they may be antagonistic to the opinions of others, as to the reckless systems of sewerage, &c., advocated by many at the present day.

In conclusion, I hope, Sir, you will give this letter the same publicity you have thought fit to give to the article in your annotations. As a public officer I know that my actions are open to criticism, and I have no wish to shirk the responsibility; but I have a right to expect that that criticism will be truthful.

I remain, Sir, yours truly,  
Maryport, July 24th, 1882. JOSEPH PEARSON, M.D.

\* \* In addition to the above letter from Dr. Pearson, we have received a local paper in which there is a letter from Dr. Pearson on Mr. Spear's report in May last, and we have also received the subjoined letter from Mr. Mathias. Taken together they are, in our opinion, confirmatory of the main points in Mr. Spear's official report, on which we commented. Mr. Mathias's letter speaks for itself, and Dr. Pearson's letter of May, in so far as it deals with matters referred to in our annotation, admits that the hospital is "insufficient" and "out of order," that "it is impossible to ascertain" the number of cases of fever, that it would be well if the Sanitary Authority could "rebuild the town," that it would be well if the cellar dwellings "could be closed as such," that "no one can deny that there is room for improvement in the scavenging," and that as regards sewerage he "would have some of it" until what amounts to perfection from an engineering point of view can be attained. The portions of our annotation in inverted commas, and to which Dr. Pearson objects, were quoted from the official report of the Local Government Board.—ED. L.

To the Editor of THE LANCET.

SIR,—In your annotation on the above subject in THE LANCET of July 22nd, after animadverting upon the wretched condition of many of the dwellings in the town, and especially as to overcrowding, you express the hope that the case quoted by Mr. Spear, the Local Government Board Inspector, in connexion with that subject "may be an exceptional one even in Maryport, whose sanitary condition seems almost incredible." But I assure you, Sir, it is not the exception, but I might almost say the rule; there are scores of wretched tenements in Maryport entirely devoid of every requirement considered absolute necessities by any civilised community, where overcrowding exists to a shameful extent, and where common decency in regard to the separation of the sexes, in many cases, is not even observed. A correspondent in the *Maryport Advertiser* very recently, in calling attention to the general insanitary condition of the town, thus describes a case in point:—"In a former communication I alluded to the dangers of overcrowding now that such a large number of extra labourers employed at the new dock are residents in the town. I was forcibly struck a few days ago with the necessity that exists for the constant supervision and attention of the inspectors in that respect. In a house in Furnace-road, consisting of a kitchen and a bedroom, where the latter was not more than 10 ft. or 12 ft. square, a man and his wife and seven children, and a lodger, a labourer at the quarries, were sleeping! The poor woman herself and one of her children were lying ill in one of the wretched beds, suffering, I have no doubt, judging from the symptoms, from typhoid fever, one of the other children having died a few days previously from the same complaint. Is not this a very sad and terrible condition of affairs, and can nothing be done to remedy or prevent its recurrence? One would think that a man and his wife and seven children were enough, in all conscience, to sleep in a room of such dimensions, without taking lodgers! And yet I have no doubt that there are numberless other cases equally sad and shocking if they were only made known."

The same correspondent, in a subsequent communication,

dated June 9th, in alluding to a fatal case of typhus fever that had occurred in a house up one of the narrow passages leading out of King-street, remarks that "these premises are utterly unfit for the habitation of a family of seven or eight persons as at present occupy it; indeed, I might say of a family at all. It consists of two small rooms, one above the other, built against the back wall of the house behind, with no means of ventilation, save by a small pane of glass in the window opening on hinges. There is no privy accommodation whatever. Fancy a boy ten years old lying ill of typhus fever in the one little room upstairs, with no means of ventilation save the little pane of glass on hinges, inhaling all day the air made poisonous by his own excretions! And what must have been the condition of the room when the rest of the family at night betook themselves to it for repose?"

From my own experience, Sir, I could give you many other cases equally bad and incredible, but perhaps these are sufficient for the present. But what are we to say or think of an authority that permits such a state of affairs to exist in its midst without taking one single step to abate or remedy it? They cannot plead ignorance, because the report of Mr. Spear brings conviction home to the mind of every intelligent being that, in this and all other respects, the sanitary condition of the town is a disgrace to any community claiming the least affinity to civilisation; and yet I am quite convinced that, unless compelled by the Local Government Board, nothing will ever be done by the local authority to carry out the recommendations of Mr. Spear.

Your obedient servant,

Maryport, July 27th, 1882.

W. B. MATTHIAS.

P.S.—As an instance of the manner in which disinfection was carried out by the sanitary authority, I may relate what took place in a miserable back dwelling in one of the passages between Catherine-street and Queen-street, whence a case of typhus fever had been removed to the infirmary, and which terminated fatally a few days after. I asked the woman if the house and furniture had been disinfected, and she replied, "Oh, yes." "What was done to it?" "Well, the inspector gave me some lime and lent me a brush and told me to whitewash the walls, and I did." "Did anyone help you?" "No." "Were the bedclothes washed and disinfected?" "No, how could they when we were using them" (it was scarcely necessary to have asked that question, as their appearance sufficiently attested the fact of their non-acquaintance with soap and water since they left the shop); "but I put the mattress out in the air for a good bit, and made it as sweet as a nut." Thus it will be seen that those things in the house, such as the furniture, and above all, the bed and bedding where the infection is sure to be the most tenacious, were absolutely left in the same condition as when the fever case was removed from them.

### SALICYLIC SILK.

To the Editor of THE LANCET.

SIR,—Mr. Lockhart Gibson, in your issue of to-day, gives the results of cases treated in Mr. Chiene's wards by means of salicylic silk. He states that the method of treatment adopted "differed from that used in Leeds in this essential—viz., in the use of no mackintosh." In this he is mistaken. Since I first brought this dressing before the notice of the profession, some eighteen months ago, I have used no other dressing in antiseptic cases, and have always used it without the mackintosh. I have reason to know that the practice of the surgeons of the Leeds Infirmary has been the same. Indeed, the chief advantage of salicylic over carbolic acid dressings lies in the fact that they can be used without the mackintosh; the wound is thus kept comparatively dry, putrefaction is less likely to occur, and early healing is induced. The only difference between the Edinburgh and Leeds practice seems to be that in Edinburgh the dressing is completed by covering the silk with a large pad of gauze; while in Leeds we dispense with the gauze pad, and substitute for it one of silk enclosed within two layers of gauze. This is a matter of little moment, but our plan has the advantage of economy, and a larger experience has shown it to be equally efficacious.

I am, Sir, your obedient servant,

Leeds, July 20th, 1882.

A. F. MCGILL.

### GLASGOW.

(From our own Correspondent.)

THE usual graduation ceremony at the University took place on Thursday, July 27th. Of the 169 aspirants to academical degrees in medicine only seventy-six were successful. Professor Charteris' valedictory address to those who had just been "capped" was full of interest and instruction; it took the form mainly of plain and practical advice regarding the various careers open to those just licensed to practise medicine, and was evidently listened to with enjoyment and profit. He pointed out the advantages likely to be derived from a residence at one of the foreign schools of medicine, though he was inclined to think that these were not so great as is generally supposed, maintaining that in the application of the theories and facts of science to the treatment and prevention of disease the English are vastly ahead of the continental nations. He then very properly warned the graduates against continuing long in the mercantile marine service should they have occasion to go to sea as ship surgeons; and concluded by indicating the qualifications necessary for success in the various branches of modern practice.

It is generally understood that our Royal Infirmary is about to lose the services of Dr. M. Thomas as superintendent. Dr. Thomas has fulfilled the duties of this very trying position for many years now with general satisfaction.

### SCOTTISH NOTES.

(From our Correspondent.)

PROFESSOR STRUTHERS was in his war-paint last week. The fighting attitude is not an unusual one with him, as some of his colleagues very well know. His hits are hard, for the most part well considered, and with an almost certain delivery. He had a congenial subject on which to address his students at the end of the summer session, and had no difficulty in proving to their satisfaction how fortunate they were to come so far north for their instruction. He showed that while in regard to the Arts course the Scottish Universities were perhaps behind those of England and Germany, such could not be said of the medical. Those connected with medical education in England believed that whatever exists there is by far the best, whereas in his opinion there was no country in Europe so far behind as England—their system of medical education was positively the worst. The medical teaching in Scotland was excellent, and if Cambridge did but a tenth part of what is done in Aberdeen in this connexion, the world would hear of it. Hard work is the characteristic of the Aberdeen Medical School. Certainly, when Dr. Struthers looks around at his splendid facilities for teaching, and feels how much these are undoubtedly due to his own exertions, when he considers his own devotion and constant assiduity as a teacher, he may well feel proud and complacent. In each of the Scottish Universities the teachers of the purely scientific branches are men whose energies and lives are devoted solely to one subject, and they may be excused for their occasional hint at the opposite conditions which obtain further south. Again, our Gairdners, Pirries, MacLagans, &c., devote their best efforts to teaching, and only lay aside their gowns when, from old age, they feel that they are no longer fit to do justice to their students. Throughout life their highest honours come from teaching, and success in practice is not allowed to detain them from their classes or their wards. All this is highly favourable to good teaching; but Professor Struthers is perhaps wrong in assuming that the English do not admit the excellence, as for many years an entirely disproportionate number of students come from that and other English-speaking countries—the best proof of the real opinion held on the question. The prize-lists of the Aberdeen University show another element of strength which the teachers fully acknowledge: I notice that in one class the first four men have their M.A. degrees. This is material easily wrought.

During the past few weeks several prosecutions—the first in Scotland—have occurred under the Factories Act. Medical men have long known that young women frequently made complaint of the lengthened hours during which they were called to work on but slight necessity.

Certifying surgeons would assist these poor people, as well as the interests of justice, were notes of the complaints made in the consulting rooms, both with regard to overtime and vitiated atmosphere, kept for the use of the inspectors in every case where the same employers were frequently shown to be at fault, and especially where private remonstrance is ineffectual. The prosecutions in Edinburgh, Dundee, and Aberdeen were merely meant as reminders; but in future greater severity will be used.

While satisfaction is generally expressed with regard to the appointment of Mr. Chiene, there was, apparently, surprise felt by many who deemed themselves the possessors of special knowledge. So much is this the case that one proposed candidate at least, and a most creditable one, felt it advisable not to put forward his claims, as he was assured that another than Mr. Chiene was certain of the appointment. To the majority of the curators—gentlemen nominated by the town council—the choice must have been most irksome, and, though they have for once been judicious in their selection, the profession would most gladly see their patronage transferred to other hands.

### IRELAND.

(From our own Correspondent.)

THE Belfast Hospital for Skin Diseases is a very valuable institution, as evidenced by the increased numbers who avail themselves of the advice and care which by it are placed within their reach. Many of these cases are among the most painful and trying, and others are of so contagious a nature that it is of importance to the community that every precaution should be taken against their spreading. The number of patients treated last year was 1167 (79 intern and 1088 extern), those admitted to the wards being very much in excess of the previous year. The expenditure was in excess of the income, but a bequest of £1000 will shortly be obtained from the executors of the late Mr. George Bann.

A vacancy has arisen in the City of Dublin Hospital for a visiting physician, in consequence of the appointment of Dr. J. Magee Finny to the King's Professorship of the Practice of Medicine in the School of Physic of the University of Dublin, which carries with it the post of physician to Sir Patrick Dun's Hospital. It is generally believed that Dr. Duffey, at present attached to Mercer's Hospital, will be selected to succeed Dr. Finny, which would cause a vacancy for a physician to Mercer's Hospital. The latter institution is one which requires purchase money for its medical and surgical appointments, the price averaging from £1000 to £1500.

Dr. Henry MacCormac, of Belfast, has recently published a pamphlet on the Etiology of Tubercle. Dr. MacCormac believing, as he does, that the cause of phthisis is due to the inhalation of rebreathed air, and that perfect ventilation is the antidote, is antagonistic to Koch's theory as to the cause of the disease—viz., that tuberculosis is a parasitic disease, the parasite being a bacillus about as long as a blood corpuscle; and that the affection is communicable by infection, or conveyed into the system by dust. The author does not contend that bacilli are not found in tuberculous subjects, but his chief argument appears to be that before there can be tuberculous bacilli the man or brute must be tuberculous.

The emigrant lodging-houses in Queenstown appear to be very much overcrowded, and the attention of the Board of Trade has been directed to the subject, which is at the present time of importance, as fever prevails in the town. It has been publicly stated that as many as 170 persons of a night have been kept in one or two of these lodging-houses; a condition of things which could not exist if the Town Commissioners would insist on the regulations required by law being strictly enforced.

Two men were suffocated on board the vessel *Woodlawn* last March, and the owners were last week fined £30 for their negligence in not having the fore-castle properly ventilated.

The death is reported at Coppenagh of a widow, Margaret Melady, at the mature age of 105.

An election for a medical officer to Portaferry Dispensary District, in the room of the late Dr. Filson, will be held

next week. The salary attached to the post is £115 per annum, and fees.

Mr. Thomas Higgins, L.R.C.S.I., medical officer of Clonsilla Dispensary District, has been elected a coroner for the Queen's County.

### PARIS.

(From our Special Correspondent.)

YESTERDAY afternoon the Academy of Medicine held its annual meeting, and a list of the prizemen and medalists was read by the Secretary. In one instance there was no award, because no memoir had been sent in for the prize, and in others the competing essays were not considered to be of sufficient merit. The Civrieux prize of £60 went to Dr. Ballet; the Capuron prize (£80) to Dr. Belugou. The Desportes prize was divided between Dr. E. Vidal, for his work on the Treatment of Prolapsus of the Rectum by Hypodermic Injections of Ergotine, and Dr. Campardon. MM. Lucas-Championnière and H. Toussaint were awarded £48 and £32 respectively, the total forming the Prix Amussat. An important prize of 10,000 francs (£400), but which is only awarded once in six years, was divided between Drs. Bigelow (of Boston) and Th. Auger, the former taking £240 and the latter £160. M. Toussaint, of Toulouse, receives an encouragement to continue his researches concerning the cholera of fowls and acute experimental septicæmia in the shape of the Barbier prize, the value of which is £240. The enumeration of all the awards would be tedious, but it may interest your readers to know what are the prizes and what the subjects for 1883. Perhaps some industrious workers in England may be stimulated to enter the list. The Prix de l'Académie is 1000 francs; the subject, to determine the Clinical Value of Antiseptic Methods in Surgical Practice. Prix Portal, 1000 francs, Is Tubercle of Parasitic Nature? Prix Civrieux, 2000 francs, Hysterical Paralysis and Contractures. Prix Capuron, 2000 francs, on the Influence of Sea-bathing in the Scrofula of Children. Prix Godard, 2000 francs, for the best work on External Pathology (Surgical Disease). Prix Barbier, for the Discovery of a Cure for any Disease reputed to be Incurable, such as Epilepsy, Hydrophobia, Cancer, Cholera; part of it may be awarded for advancement in this direction. Prix Desportes, 1500 francs, for the best work on Medical Therapeutics. Prix Daudet, 1500 francs, Lymphadenoma. A prize of 2000 francs, under the name of the Prix de l'Hygiène de l'Enfance; subject, to determine by precise Observation the Role of First Dentition in Infantile Pathology. Prix Amussat, 2000 francs, for a work based upon Anatomy and Experiment leading to progress in Surgical Therapeutics. Prix Saint-Lager, 1500 francs, for the Discovery of a Cure for Goitre. Prix Saint Paul, 25,000 francs, for the Discovery of a Cure for Diphtheria; the interest of the capital may be awarded as an encouragement for work in this direction.

The account given in the last letter of M. Laborde's lecture, and the disturbance created by a lady anti-vivisectionist, does not appear to be quite correct. The meeting, instead of breaking up in confusion, was only interrupted for a few minutes, during which time the fair zoophile let off her virtuous indignation, and declared that the intended demonstrations should only take place after her blood had been mingled with that of the frogs. Force being out of the question, and the lady having determined to occupy the position she had achieved, M. Laborde invited her to share the professorial chair, and act, as it were, as censor, promising to pay attention to any objections she might make. Thanks to his tact, the lecturer was able to carry out his programme; and when he had finished he congratulated his unexpected colleague on the opportunity she had given him of vindicating science. This correction is worth making, the more so as a great deal of unnecessary fuss and misrepresentation have crept into the papers about the incident.

At the present moment there is a case of nervous disease in the Beaujon Hospital which seems to interest all Paris. The daily papers publish bulletins concerning the *dormeuse*, as the patient is termed; and as her identity is unknown, everyone is looking forward with curiosity to the time when the sleeper shall awaken and unravel the mystery. Briefly the facts are as follows: Between two and three months ago, on May 12th, the police

found a woman in a state of intoxication. They took her to the station, and at that time she was able to articulate a few words. hiccupping, "Oh, what a lot of beer I have drunk." In the course of the evening she sank into a state of torpor, and was taken to the hospital, where she has remained ever since. For seventy-four days she remained in a state of lethargy, kept alive by liquids only, and not uttering a sound. When she was found to be *enceinte*, it was thought that the expulsion of the fœtus would be sure to lead to some change; but about a fortnight since a five-month miscarriage occurred, the patient remaining to all appearance absolutely unconscious. It was then determined to try cold douches, and the second was so far successful that the patient is now able to swallow solid food. She remains, however, to a certain extent aphasic, and unable to give any information concerning herself. The fact of her wearing a number of religious medals has the more excited public curiosity, and she is popularly supposed to have been abducted from a convent.

Paris, Aug. 2nd, 1882.

### ROYAL COLLEGE OF SURGEONS.

At an ordinary meeting of the Council, held on Thursday last, the consideration of the resolution, "That in future all candidates for the Primary or Anatomical and Physiological Examination, whether for the diploma of Member or of Fellow of the College, be only required to attend one winter course of lectures on Anatomy instead of two courses of such lectures," was, upon amendment, deferred until the meeting of the Council in March, 1883. The recommendation of the Joint Committee, "That the periods at which the Examination in Elementary Anatomy and Physiology shall be held, be determined by the teachers at the several medical schools, provided that an interval of not less than six months shall elapse between the date at which the candidates shall have passed the Examination and the date of their presenting themselves for the Primary Examination at the College," was, after some discussion, approved and adopted.

Mr. T. M. Stone was granted a retiring pension of £300 per annum in consideration of his long and valuable services.

A letter was read from Mr. Birkett resigning his seat as a Member of the Court of Examiners, the vacancy to be filled up at the quarterly meeting of the Council in October next.

### MEDICAL NOTES IN PARLIAMENT.

In the House of Commons on Thursday, July 27th, a petition was presented from Batley in favour of the Infectious Diseases Notification Bill. A copy was presented of the report of the Commission on Small-pox and Fever Hospitals in the Metropolis.

On Friday, Mr. Trevelyan stated, in answer to Mr. Biggar, that the Local Government Board had received contradictory reports from Belfast as to the alleged refusal of the master of the workhouse to admit aged and infirm persons who had urgent orders for admission, and that a fuller inquiry had been instituted.

#### *The Army Hospital Corps.*

General Fielden asked the Secretary of State for War whether he had any objection to state the result of the inquiry by the Committee presided over by Sir E. Wood into the charges of inefficiency and misconduct brought against the men of the Army Hospital Corps who served in South Africa; and whether he intended to take any action in the matter.—Mr. Childers said the general result of the inquiry was that the more serious allegations against the Army Hospital Corps had not been substantiated. He had, however, with the concurrence of the Duke of Cambridge, appointed a committee of inquiry into the whole organisation of the corps, and he hoped to be able to consider its report before he prepared the estimates for next year.

#### *Adulterated Butter.*

In a discussion on the Board of Trade vote in Committee of Supply, Mr. Biggar complained of the injustice of holding the retail dealer liable to a penalty for selling adulterated butter, whilst the importer of the same material carried on

his business with impunity.—Mr. Chamberlain replied, that the Adulteration Acts rendered a person liable to a penalty of £20 who sold oleomargarine as butter, without declaring to the purchaser the nature of the material.

On Monday, a petition was presented from Barry against the Lunacy Districts (Scotland) Bill. This Bill stands for the Committee stage on Friday.

On Tuesday, four petitions were presented from London and one from Norwich in favour of the registration of midwives. A petition for redress of the grievances of militia surgeons was presented from the South Wales Branch of the British Medical Association.

#### *Coffee Mixtures.*

In Committee on the Customs and Inland Revenue Bill there was considerable debate on the Government proposal for the taxation of imitations of coffee and of coffee mixtures. An amendment by Mr. Maguac, providing that each packet should be labeled with a prominent statement of the substances of which the mixture is composed, was agreed to. Mr. Cavendish Bentinck moved another proviso, that the percentage of coffee contained in the mixture should also be stated, but this was resisted by the Government on the ground that it would be impracticable to state the percentages. In the course of the discussion Mr. Macfarlane warmly complained that the poor were being cheated and poisoned by adulteration. Mr. Courtney expressed his opinion that the proposal, if adopted, would be a piece of "great-grandmotherly" legislation. Eventually the amendment was rejected by 114 to 73. On Wednesday, an additional amendment was inserted permitting the sale of coffee mixtures in quarter-pound packets; previously the limit was half a pound.

#### *The Carriage Duty.*

Clause 9 of the Customs and Inland Revenue Bill, which related to the proposed increase of the carriage duty, was struck out.

During the evening a supplementary estimate was laid on the table for the purpose of augmenting the grant in aid of medical relief in Scotland from £10,000 to £20,000.

#### *Navy Hospitals.*

On Tuesday, Mr. Gorst asked whether, in the event of a hospital-ship being sent out to Alexandria or a naval brigade being landed in Egypt, the services of any of the Sick Berth Staff of the Royal Navy now employed in the Royal Navy Hospitals would be utilised.—Mr. Campbell-Bannerman: Yes. The services of any of the Sick Berth Staff, whether at present employed in the navy hospitals or in the flagships, will be utilised in Egypt as required.

On Wednesday, the order for the second reading of the Bill for repealing the compulsory clauses of the Vaccination Acts was discharged, and the Bill was withdrawn. A copy was presented of the 37th report of the Scotch Board of Supervision of Poor Relief and Public Health.

#### *Analyses of Butter and Milk.*

Lord E. Cecil asked the President of the Board of Trade whether his attention had been drawn to the report of Mr. Blyth, analyst under the Adulteration of Food Act to the Devonshire Court of Quarter Sessions, dated June 13th, 1882, in which, speaking of the adulteration of butter and milk, he compared the difference of limit between the public analysts of 1874 and that of the Somerset House certificate at the present time; and whether he proposed to take steps in the interest of the public to raise the standard of purity in both these articles.—Mr. Dodson confirmed the citation from Mr. Blyth's report, and said there was no doubt as to the difference of opinion of those two bodies. The Somerset House analysts, however, were not alone in their opinion. The Local Government Board were now in communication with them on the subject; but at present he was not prepared to say whether it was practicable to fix any such standard of purity with regard to these natural products as would effectually protect the public from adulteration whilst securing the honest dealer from persecution. Mr. Dodson said further that the Local Government Board were in communication with the chief analyst at Somerset House, to ascertain whether, in his opinion, anything could be done to improve the present condition of things.

#### *Alkali Works.*

Mr. Dodson, in reply to questions by Mr. A. Arnold and Mr. Gore Langton, said an efficient system of inspection

was being built up under the new Act, but some experience would be necessary to fix the number of inspectors required. The list of works under inspection would be printed.

*The Norwich Vaccination Inquiry.*

Mr. Dodson replied to Mr. P. A. Taylor that the inquiry by the medical inspector at Norwich was not yet completed. He had heard that since the first group of cases a death very similar had occurred of a recently vaccinated child, but he had at present no information to show that it was due to vaccination.—Mr. Taylor said he would repeat his question on Tuesday.

*Classification of Butter Substitutes.*

Viscount Folkestone asked the President of the Board of Trade when the Statistical Inquiry Committee that was examining into the subject of the better classification of butter, oleomargarine, and other butter substitutes, was likely to issue their report, and whether he would communicate the result of that inquiry to the House.—Mr. Chamberlain said the report would probably be ready in a few days. It was for the Treasury to decide whether it should be laid on the table. It would deal with many other subjects besides those to which the noble lord referred.

*Emigrant Ships.*

Mr. Moore asked the President of the Board of Trade whether there were a number of emigrant ships which, on their homeward voyages, came to this country laden with cattle, returning to America with large numbers of steerage passengers; and if he could state what, if any, special precautions were enforced for the disinfecting and cleansing of those ships after each voyage with cattle.—Mr. Chamberlain said the vessels were thoroughly disinfected and cleansed after each voyage. They were subsequently inspected by a Board of Trade emigration and sanitary officer. Emigrants would not be allowed to travel by these vessels if they were in a condition dangerous to health.

*Vivisection.*

In the House of Lords the Earl of Shaftesbury had the following notice on the paper: To ask the Under-Secretary of State for the Home Department whether Dr. Charles S. Roy, having received a licence for vivisection in 1881, received also a certificate for the same year permitting experiments on living dogs and cats; also whether he received any such certificate for the year 1882. The noble earl, however, was not in his place, and the question was postponed.

## Obituary.

HENRY DODGSON, M.D., L.R.C.S.E., &c.

DR. HENRY DODGSON, who died on the 10th ult. at his residence, Derwent House, Cockermouth, in the full vigour of manhood, after a few days' illness, of typhoid accompanied by pneumonia, was born in that neighbourhood forty-nine years ago of a good old Cumberland family. He studied at the Universities of Edinburgh and Paris, graduating M.D. at Edinburgh in 1856. Since then he had practised in Cockermouth and the neighbourhood for many miles round. Those who had the privilege of knowing him cherish the memory of his bright and manly expression, united with great modesty. Dr. Dodgson was beloved by all who knew him, and was buried with every mark of respect and honour, both military and Masonic, he being a major of volunteers and one of the best officers in the county, and Past Grand Senior Deacon of his Province. His contributions to medical, astronomical, meteorological, and other sciences made him well known to the scientific world.

**PRESENTATION.**—Dr. William Sinclair, house-surgeon at the Aberdeen Royal Infirmary, has been presented with a handsome amputating case by the students of his surgical class, in recognition of the care and efficiency with which he conducted the meetings.

The Brighton and Sussex Eye Infirmary is being enlarged, or rather reconstructed, at a cost of £5000. The building will, it is expected, be ready for occupation by the end of the present year.

## Medical News.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON.**—The following gentlemen were admitted Fellows of the College on July 27th:—

Blanc, Henry, M.D. Montpelier, Bombay.  
Grant, James Alexander, M.D. Montreal, Ottawa.

The following gentlemen were on the same day admitted Members of the College:—

Grabham, George Wallington, M.D. Lond., Earlswood.  
Herringham, Wilmot Parker, M.B. Oxon., St. Bartholomew's Hospital.  
Jessop, Charles Moore, Whitehall-place.  
Jones, Arthur Henry, M.D. Lond., Northampton.  
MacLagan, Thomas John, M.D. Edin., Cadogan-place.  
Mitra, Jogendra Nath, Keppel-street.  
Richardson, Gilbert, M.D. Dub., Roland Gardens.  
Routh, Amand Jules McConnell, M.B. Lond., Upper Montagu-street.  
Shaw, John, M.D. Lond., Willoughby-road.

The following gentlemen were also admitted Licentiates of the College:—

Alpin, William George Patrick, Commercial-street.  
Bamford, Charles Robert, Uttoreter.  
Banatvala, Hormasjee Edaljee, Endsleigh Gardens.  
Bass, Frederick, Union-road.  
Bertram, Benjamin, Montagu-street.  
Blatherwick, Henry, Rochester.  
Buckell, William Robert, Romsey.  
Cameron, John, Bilston.  
Challinor, Oedric, Reedworth-street.  
Chown, Henry Havelock, M.D. Kingston, Great Ockham-street.  
Collins, Robert John, Middle Mall.  
Cooper, Walter, South Hill, Park-road, Croydon.  
Cox, Roland Frederic, Ryder-terrace, Twickenham.  
Day, John Roberson, Camden-road.  
Dendy, Walter Chester, Guy's Hospital.  
Downing, Charles, Falmouth.  
Durant, Robert James Anderson, St. Thomas's Hospital.  
Evans, Thomas Jones, Edward-street.  
Frost, George, Bedford-square.  
Greaves, Thomas, M.D. New York, Regent-square.  
Hoskyn, Donald Templeton, Isleworth.  
McMillan, John Furse, Middlesex Hospital.  
Marston, Francis Ernest, Ludlow.  
Pocock, Alfred George Clarke, Brixton-road.  
Pritchard, Samuel Evan, Tower Hamlets Dispensary, Stepney.  
Reynolds, James Jones, Stoke-by-Clare.  
Robinson, Wilford Vidal, Saffron Walden.  
Strachan, William Henry Williams, Guy's Hospital.  
Tait, Henry Brewer, Highbury Park.  
Thornton, Hastwell William, M.D. McGill, Nicholas-street.  
Todd, Charles Edward, Sussex Gardens.  
Toller, Chas. Wm. Edward, St. Bartholomew's Hospital.  
Viney, Josiah Ernest, M.B. Camb., Fernwood, Highgate.  
Wightwick, Fallon Percy, Folkestone.  
Williams, Evan, St. Paul's Crescent.  
Zimmermann, Benjamin Frazier, Ealing.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—

Dr. William Joseph Lunn, the senior surgeon to the Hull Infirmary, was elected a Fellow of the College at a meeting of the Council on the 3rd inst., his diploma of Membership bearing date May 14th, 1883.

The following gentlemen, having passed the required examination for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 27th ult.:—

Dawson, George Herbert, Moor Allerton.  
Dixon, Henry Charles, Putney.  
Downman, Charles Frederick, Castle Hill.  
Dutton, William Henry, M.B. Edin., Edinburgh.  
Faunce, Charles Edmund, L.S.A., Guernsey.  
Holcroft, Henry, Sevenoaks.  
Lynam, Robert Garner, L.S.A., Stoke-on-Trent.  
Northcott, Arthur, L.S.A., Fulham.  
Perez, George Victor, L.S.A., Tenosiffa.  
Williams, John Alexander, M.B. Aberd., Enfield.  
Wise, Charles Henry, L.S.A., Llanconston.

The following gentlemen were admitted Members of the College on the 28th ult.:—

Baattie, Robert, M.D. Queen's Univ. Irel., Ballymena.  
Berry, John Bourne, L.S.A., Barna, Galway.  
Bostock, John, L.S.A., Osgathorpe, Leicester.  
Harris, Walter Thomas, L.S.A., Lloppien, Devon.  
Hoyland, Stanley Stenton, L.S.A., Botherham.  
Leadbeater, Thomas Edward, L.S.A., Bromley-by-Bow.  
Morse, Thomas Rickett, L.S.A., Cheltenham.  
Pollard, George Samuel, South Walsham.  
Rogers, Thomas Edward, L.S.A., Bickerton, Devon.  
Salmon, Arthur Guy, L.S.A., Truro, Cornwall.

The following gentlemen were admitted Members of the College on the 31st ult.:—

Bott, Joseph, L.S.A., Dunmow, Essex.  
Bevor, Hugh Reeve, L.S.A., Hingham, Norfolk.  
Cox, Roland Frederic, L.R.C.P. Lond., Twickenham.  
Durant, Robert James Anderson, L.R.C.P. Lond., Bengal.  
Howard, R. J. Bliss, M.D. McGill Coll., Montreal.

Hudson, Ernest, L.S.A., Harleston, Norfolk.  
 Lovegrove, Thos. Ernest, L.S.A., Wollaton, near Nottingham.  
 Roe, Arthur Dumville, B.A. Cantab., Ekeles.  
 Tate, Alan Emondson, L.S.A., Trent, Somerset.  
 Voss, Francis Henry Vivian, L.S.A., Clanton-square.  
 Williams, Evan, L.R.C.P. Lond., Bala, North Wales.

The following gentlemen were admitted Members of the College on the 1st inst.:-

Finch, Thomas, B.A. Cantab., Torquay.  
 Jones, Owen Clayton, L.S.A., Philipot-street.  
 Thomas, John Henry, L.S.A., Tenby.

Of the 284 candidates examined during the past fortnight 124 passed to the satisfaction of the Court and obtained their diplomas; 48 passed in Surgery, and when qualified in Medicine and Midwifery will be admitted Members; the remaining 112 failed to reach the required standard, and were referred for six months' further professional study. Ten candidates who had passed in Surgery at previous examinations, having subsequently obtained a Medical qualification recognised by the College, were also admitted Members. This is the last examination for the Membership of the College until November. The Museum of the College, which is now undergoing painting and decoration, will be closed from this date until further notice.

UNIVERSITY OF LONDON. — The following is the list of candidates who passed the recent Preliminary Scientific (M.B.) Examination:—

#### FIRST DIVISION.

Adams, Charles Edward, University College.  
 Althorp, Charles Frederick Manning, private study.  
 Balgarnie, Wilfred, Yorkshire College.  
 \*Basu, Jagadish Chunder, B.A. Calcutta, Christ's Coll., Camb.  
 †Bidwell, Leonard Arthur, St. Thomas's Hospital.  
 Blackler, Henry John, Guy's Hospital.  
 Blackston, Charles Reginald, King's College.  
 †Brennan, Joseph Richard, Owens College.  
 Brock, Ernest Henry, Guy's Hospital.  
 Brook, Wm. Henry Breffit, St. Bartholomew's Hospital.  
 \*Brown, Arthur Edward, private tuition and Univ. College.  
 Cameron, Robert Watson, B.A., Owens College.  
 †Canney, Henry Edward Leigh, University College.  
 \*Carnegie, Douglas John, Epsom College.  
 Clarke, James Jackson, St. Bartholomew's Hospital.  
 Clarke, William Frederick, Guy's Hospital.  
 Cook, Samuel Bird, St. Thomas's Hospital.  
 \*Cox, Alfred Edward, St. Thomas's Hospital.  
 Crook, Herbert Evelyn, Guy's Hospital.  
 Davies, Ernest Reuter, Guy's Hospital.  
 Dewhurst, John Henry, Owens College.  
 \*Edge, Frederick, Owens College.  
 Elliot, William Henry Wilson, Guy's Hospital.  
 Evans, Isabel Clare, Mason College, Birmingham.  
 Gilchrist, Thomas Caspar, Owens College.  
 Harper, William Norton, Huddersdon School.  
 Helsham, Hugh Paul, St. Thomas's Hospital.  
 Jucks, Cyril William, University College.  
 †Joly, Antoine Maurice, University College.  
 Lains, Alfred William, King's College.  
 †Legg, Walter Littlewood, Yorkshire and Clifton Colleges.  
 Macdonald, Isabella Macdonald, Univ. Coll. and private tuition.  
 \*Macevoy, Henry John, St. Joseph's College, Clapham.  
 May, William Page, University College.  
 Pagden, Trayton Charles, St. Bartholomew's Hospital.  
 Pernewan, William, University College.  
 Rodfern, John Joseph, Queen's College, Belfast.  
 Roper, Harold Kennaway, Guy's Hospital.  
 Sansom, Harry Arthur, Univ. Coll. and St. Thomas's Hosp.  
 \*Seville, Charles Frederick, Owens College.  
 Shirliff, Edward Dickinson, St. Thomas's Hospital.  
 Simpson, Charles Shackleton, Guy's Hospital.  
 Smith, Alex. Rochfort, St. Barthol. Hosp. and private study.  
 Smith, Hugh, Guy's Hospital.  
 Solly, Ernest, St. Thomas's Hospital.  
 †Stacy, John Herbert, Univ. of Edin. and Univ. Coll. Lond.  
 †Stephens, Richard John, King's College.  
 Thompson, James Edwin, Owens College.  
 Tomlinson, William Henry, Owens College.  
 Toogood, Fredk. Sherman, Hartley Institution and Univ. Coll.  
 Tunstall, John Ogle, University College.  
 Wheaton, Samuel Walton, St. Thomas's Hospital.  
 Wheeler, James Atkin, University College.  
 †Wilkinson, Percy John, Owens College.  
 \*Wray, Richd., Spalding, Yorkshire and Elmfield Colleges.

#### SECOND DIVISION.

Anstie, William Charles, University College.  
 †Aveline, Henry Talbot Sidney, University College, Bristol, and private study.  
 \*Barker, George Henry, University College, Bristol.  
 Biddlecombe, Edward Henry, St. Bartholomew's Hospital.  
 Bidwell, Lawrence, Guy's Hospital.  
 Brown, Arthur Thomas, Guy's Hospital.  
 Burghard, Frédéric François, Guy's Hospital.  
 Baras, James, Owens College.  
 Barrell, Arthur William, London Hospital.  
 Carter, Weldon Cragg, Owens College.  
 Conolly, Charles Hamilton, St. Bartholomew's Hospital.  
 Coryn, Herbert Alfred William, Charing-cross Hospital.  
 Craig, Henry Edward, Guy's Hospital.  
 Crouch, Charles Percival, St. Bartholomew's Hospital.  
 Davidson, Harold, St. Bartholomew's Hospital.

Davis, Arthur Hildsworth, St. Bartholomew's Hospital.  
 \*Dean, Henry Percy, University College.  
 Dobson, Leonard Charles Talbot, St. Bartholomew's Hospital.  
 \*Duncan, Charles Herbert, Epsom College.  
 Featherstone, William Barltrop, Queen's and Mason's Colleges, Birmingham.  
 Fisher, Theodore, Guy's Hospital.  
 Freeman, Ernest Carrick, St. Thomas's Hospital.  
 Furnivall, Bryan, St. Bartholomew's Hospital.  
 Godfrey, Albert Edward, St. Thomas's Hospital.  
 Halliwell, Thomas, St. Peter's Sch., York, and Yorkshire College.  
 \*Hammersley, Percy Herbert Vickers, St. Barthol. Hosp.  
 \*Haring, Nathan Charles, Owens College.  
 Harris, Frances, University College and London School of Medicine for Women.  
 Hensley, Arthur Egerton, King's College.  
 †Holloway, Samuel Frederick, Guy's Hospital.  
 Joseph, Arthur Hill, University College, Bristol.  
 Kanthack, Alfredo Antunes, University College, Liverpool.  
 \*Kell, Edmund Delacourt, London International College.  
 Kelson, William Henry, London Hospital.  
 Kingsford, Edward Claude, Guy's Hospital.  
 Lang, Arthur Joseph, Epsom College.  
 †Legg, Cyrus, Guy's Hospital.  
 Lindow, Albert, King's College.  
 Lys, Henry Grabham, private tuition.  
 Marshall, Charles Frederick, Owens College.  
 Moore, Robert Lee, Queen's College, Belfast.  
 O'Reilly, George Hartley, private study.  
 \*Pallthorpe, Mary Elizabeth, London Sch. of Med. for Women.  
 Pickering, Rowland Neville, Umfreville, private tuition.  
 Prall, Samuel Esmond, Guy's Hospital.  
 Pugh, John Williamson, University College of Wales and London Hospital.  
 Randall, Ernest Bldgood, University College.  
 Risdon, William Newt, Guy's Hospital.  
 †Roberts, David Foulkes, Owens College.  
 Scott, Arnold, Guy's Hospital.  
 Shadwell, Bertrand, St. Bartholomew's Hospital.  
 \*Smith, Edmond Fauriel, St. Bartholomew's Hospital.  
 Smith, Henry Ernest Hill, King's College.  
 Smith, John Anderson, St. Bartholomew's Hospital.  
 \*Smith, Robert Gillies, Univ. of Aberdeen and St. Bartholomew's Hospital.  
 †Sprent, Frank Arthur, St. Bartholomew's Hospital.  
 Stedman, Frederick Osmond, Charing-cross Hospital.  
 Stocks, William Percy, Owens College.  
 \*Stokes, Frederick William, Mason College, Birmingham.  
 Swayne, Walter Carlos, Bristol Medical School.  
 Wallis, William Kay, Owens College.  
 Wethered, Frank Joseph, Bristol Medical School.  
 Whitcombe, William Sandford, Epsom College.  
 Williams, Frederic Newton, St. Thomas's Hospital.  
 Wynter, Andrew Ellis, St. Bartholomew's Hospital.  
 \* Passed in the Mathematics of the Intermediate Examination in Science, and are thus admissible to the B.Sc. Examination.  
 † Examination in Botany postponed.  
 ‡ Examination in Physics postponed.  
 § Examination in Zoology postponed.

ARMY MEDICAL SERVICE. — The following is the list of Surgeons on probation in this Service who were successful at both the recent London and Netley examinations. The marks gained at Netley are not shown in this table, as the final positions of these gentlemen are not affected by them:—

	Marks.		Marks.
* S. Westcott ..	2295	H. S. McGill ..	2065
† H. R. Whitehead ..	2230	A. A. Pechell ..	2000
B. M. Skinner ..	2200	C. R. Tyrrell ..	2050
C. R. Bartlett ..	2195	J. Hickman ..	1980
J. D. T. Reckitt ..	2175	W. B. Thomson ..	1975
T. A. P. Marsh ..	2150	H. E. Deane ..	1945
R. Kirkpatrick ..	2140	S. O. Stuart ..	1940
A. C. A. Alexander ..	2095		

\* Gained the Martin Memorial Gold Medal.

† Gained the Montefiore Medal and Prize of 20 guineas.

INDIAN MEDICAL SERVICE. — The following is the list of Surgeons on probation in this Service who were successful at both the recent London and Netley examinations. The final positions of these gentlemen are determined by the marks gained in London added to those gained at Netley, and the combined numbers are accordingly shown in the list which follows:—

	Marks.		Marks.
* H. H. R. Charles ..	5455	J. P. Barry ..	4922
† G. Duncan ..	5025	A. V. Anderson ..	4690
W. A. Sykes ..	4875	E. W. Reilly ..	4445
R. W. S. Lyons ..	4560	J. Scott ..	4150

\* Gained the Herbert Prize, the Parkes Memorial Bronze Medal, and the Montefiore Second Prize.

† Gained the Prize in Pathology.

APOTHECARIES' HALL. — The following gentlemen passed the examination in the Science and Practice of Medicine, and received certificates to practise, on July 27th:—

Grigg, William Henry, Torrington, Devon.  
 Hulseberg, John Wild, Gipsy Hill, Upper Norwood.  
 Power, Charles Frederic, Bexhill, Hastings.  
 Roberts, Thomas Pritchard, Twyford, near Winchester.

Watson, Robert Walker, Highbury New Park.  
Watson, William, High-street, Rochester.

The following gentlemen also on the same day passed the Primary Professional Examination:—

William Henry Carrington, Guy's Hospital; Charles John Maddison, And t Essex Hospital; William Kirman Pauli, Coaring-cross Hospital.

**OBSTETRICAL SOCIETY.**—The Library of this Society will be closed from August 14th to September 14th.

**MR. AXFORD, M.R.C.S.**, for thirty years Medical Officer of No. 3 District and the workhouse of the Bridgwater Union, has received a superannuation allowance of £25 a year.

A **BAZAAR** has been opened at Lydney for the purpose of raising funds for providing a hospital dispensary and experienced nurses for the poor of the district.

**EASTBOURNE HOSPITAL FUND.**—The result of the bazaar just closed is that £500 was realised towards the funds of the new Memorial Hospital, leaving about £1000 to be collected by the time the building is ready for opening.

The formal opening of the new wing of the West of England Sanatorium at Weston-super-Mare took place on the 26th ult. The institution began in 1868, as a cottage hospital with four beds, and is now capable of accommodating 100 patients.

**METROPOLITAN ASYLUM, CATERHAM.**—Mr. George S. Secombe, the Senior Assistant Medical Officer of this Asylum, having been appointed by the Secretary of State for the Colonies to fill the post of Medical Superintendent to the Trinidad Royal Asylum, has resigned his office at Caterham, and was recently presented with a handsome repeating chime clock by the staff of the Asylum as a token of their regard and esteem. The presentation was made by Dr. Stanley Elliot, the Medical Superintendent, who referred to Mr. Secombe's long service, and also the interest he had taken in promoting the happiness of the patients during his residence at Caterham.

**NATIONAL ASSOCIATION FOR THE PROMOTION OF SOCIAL SCIENCE.**—At the congress of this Association, to be held at Nottingham from Sept. 20th to the 27th, the following questions will be discussed in the Health Department, the presidency of which has been accepted by Sir Rutherford Alcock, K.C.B.:—1. How does the employment of mothers in mills and manufactures influence infant mortality; and ought any, and if so what, restrictions to be placed on such employment? 2. What reforms are desirable in the administration of hospitals? 3. What are the advantages of a system of notification of infectious diseases, and what are the best means of carrying the same into execution?

An interesting event, proving that the public are not always indifferent to the risks and anxieties involved in medical practice, especially the work of union surgeons, has just taken place in Buntingford. The labours of Dr. Smith, medical officer of the West District and the workhouse of the union, had recently, it appears, been unusually heavy and perilous in consequence of the existence of a large amount of infective disease in the infirmary. The infection, carried home by the doctor, seized upon his children, necessitating their isolation. A few friends and patients of Dr. Smith have accordingly presented a handsome tea and coffee service to Mrs. Smith as a token of sympathy with her in her trying experience in being isolated from friends in nursing her children.

## Medical Appointments.

*Intimations for this column must be sent DIRECT to the Office of THE LANCET before 9 o'clock on Thursday Morning at the latest.*

**BARNES, ROBERT, M.D., F.R.C.P.** has been elected one of the Honorary Consulting Physicians to the Chelsea Hospital for Women.

**BOUCHER, ARTHUR HENRY, M.D. Edin.**, has been appointed House-Surgeon to the East Suffolk Hospital, Ipswich.

**CAMPBELL, PATRICK EDWARD, M.B., C.M.**, has been appointed Senior Assistant Medical Officer to the Metropolitan District Asylum, Caterham, Surrey, vice G. S. Secombe, resigned.

**CRALLAN, GEO. EDW. J., B.A. Cantab., M.R.C.S., L.S.A. Lond.**, has been appointed Assistant Medical Officer to the County Lunatic Asylum, Cambridge, vice Clun, resigned.

**CUNNINGHAM, —, M.R.C.S.**, has been appointed Medical Officer for the First District of the Romford Union, vice McClure, resigned.

**ERWIN, SAMUEL JAMES, L.R.C.P. Ed., L.R.C.S. Ed.**, has been appointed Medical Officer and Public Vaccinator for the Openshaw District of the Chorlton Union, vice Brebner, resigned.

**HATTON, G. STOKES, M.D., M.S. Dur., M.R.C.S., L.S.A. Lond.**, has been appointed House-Surgeon (Senior Medical Officer) to the North Staffordshire Infirmary.

**MOULLIN, C. W. MANSELL, M.D. Oxon., F.R.C.S. Eng.**, has been appointed Junior Assistant-Surgeon to the London Hospital, vice Tay.

**NEWCOMBE, FRANK, M.R.C.S., L.S.A. Lond.**, has been appointed Medical Officer for the Newton-on-Trent District of the Gainsborough Union.

**SMALLMAN, BENJ. F., M.R.C.S., L.S.A. Lond.**, has been appointed Medical Officer for the Sutterton District of the Boston Union.

**SPACKMAN, HENRY ROBERT, L.R.C.P. Lond., M.R.C.S., L.S.A. Lond.**, has been appointed House-Physician to the Wolverhampton and Staffordshire General Hospital, vice Mortimer, resigned.

**TINDALE, WENTWORTH RAYNES, M.B., C.M. Aber., L.R.C.P. Lond., M.R.C.S.**, has been appointed Medical Officer for the New Hampton District of the Kingston Union.

**WIGO, ALFRED E., M.D., L.R.C.P., M.R.C.S., L.S.A. Lond.**, has been appointed Honorary Medical Officer to the Children's Hospital, Adelaide, South Australia.

## Births, Marriages, and Deaths.

### BIRTHS.

**BADCOCK.**—On the 25th ult., at Buckingham-place, Brighton, the wife of Lewis Carter Badcock, M.D., of a son.

**EUSTACE.**—On the 30th ult., at Lowestoft, the wife of Surgeon-Major Edward Eustace, Army Medical Department, of a daughter.

**GOODHART.**—On the 21st ult., at Hervey-road, Blackheath, S.E., the wife of James F. Goodhart, M.D., F.R.C.P., of Weymouth-street, W., of a son.

**INGLEDEW.**—On the 30th ult., at 17, New-road, Woolwich, the wife of Geo. Ingledeu, Surgeon, of a son.

**LAST SMITH.**—On the 27th ult., at Mayfield, Torquay, the wife of Edward Last-Smith, L.R.C.P.E., L.R.C.S.E., of a daughter.

**LEWIS.**—On the 27th ult., at Radnor Cottage, Houston, Renfrewshire, the wife of William Lewis, M.D. Glas., L.R.C.P. Ed., L.R.C.S. Ed., &c., of a daughter.

**NICHOLLS.**—On the 9th ult., at Dominica, West Indies, the wife of H. A. Alfred Nicholls, M.D., of a son.

**VAN GEYZEL.**—On the 29th June, at Bangalore, India, the wife of Surgeon J. L. Van Geysel, Indian Medical Department, of a daughter.

**WORLEY.**—On the 23rd ult., at Brook Lodge, De Beauvoir-road, N., the wife of William Charles Worley, L.R.C.P. Lond., of a daughter.

### MARRIAGES.

**BECKINGSALE—SMITH.**—On the 28th ult., at Christ Church, Lancaster-gate, Daniel Loftus Beckingsale, M.D., of Sydney House, Bedford-park, Chiswick, second son of J. E. Beckingsale, F.R.C.S., J.P., to Amy Florence, adopted daughter of the late George Smith, Esq., of Melmoth House, Ryde.

**COLEMAN—MCKIE.**—On the 27th ult., at St. Augustine's, Highbury New-park, Charles Alfred Coleman, M.D., of Hill-view, Streatham-common, to Jessie Mitchell, youngest daughter of the late Thomas McKie, of Halifax, Nova Scotia.

**GREEN—BLAKISTON.**—On the 29th ult., at the Parish Church of St. Andrew's, Rugby, George Richard Green, M.R.C.S. & L.R.C.P.E., of Inkberrow, near Redditch, to Maude Douglas, eldest daughter of J. B. Blakiston, M.A., Her Majesty's Inspector of Schools.

**SANKET—HALLER.**—On the 27th ult., at Baschurch, near Shrewsbury, by the Rev. Douglas P. Ware, Herbert R. Octavius Sanket, M.B. Lond., to Marie A. Haller, eldest daughter of the late Dr. Moritz Haller, Landesgerichtsarzt, of Vienna.

**WALKER—GARDE.**—On the 24th ult., at St. Jude's, Southsea, Surgeon-Major John Walker, B.A., M.B. T.C.D., Army Medical Department, only surviving son of Samuel Walker, Esq., Portsea, county Londonderry, to Mirrie, eldest daughter of Henry Prendergast Gard, Esq., Barrister-at-Law.

### DEATHS.

**BRUSH.**—On the 8th ult., at Norwalk, Conn., Francis V. Brush, M.D. New York, aged 38.

**ELKINS.**—On the 21st ult., suddenly, at Wylde-green, Erdington, near Birmingham, Charles Elkins, M.R.C.S., of Denmark Villa, Weston-super-Mare, aged 78.

**HOPKINS.**—On the 1st inst., at Highbury New-park, N., Alfred Boyd Hopkins, M.R.C.S., aged 48.

**HURST.**—On the 29th ult., at St. Mary's-square, Kennington, William Hurst, M.R.C.S., aged 68.

**MALE.**—On the 29th ult., at Penn House, Yeovil (the residence of his brother-in-law), Henry D. Male, M.D. Brus., L.R.C.P. Lond., M.R.C.S., of Victoria-park-square, London.

**PEPLOW.**—On the 27th ult., at Lower Tooting, Surrey, Joseph Peplow, M.D., L.R.C.P., late of Great Russell-street, W.C., aged 76.

**SAYER.**—On the 30th ult., at Kenninghall, Norfolk, Thomas John Sayer, Surgeon, aged 58.

**SMITH.**—On the 31st ult., at the Paddington Provident Dispensary, Star-street, Edgware-road, William Smith, M.R.C.S., for 42 years House-Surgeon to the above institution, aged 71.

**WOODWARD.**—On the 25th ult., at King's Lynn, Edwin Woodward, L.R.C.P., in his 48th year. No cards.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

## Notes, Short Comments, and Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*We cannot prescribe, or recommend practitioners.*

*Local papers containing reports or news-paragraphs should be marked.*

*All communications relating to the editorial business of the journal must be addressed "To the Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

### THE MEDICAL PROFESSION AND FRIENDLY SOCIETIES.

We are sorry to see "The Prince of Wales" Lodge, Devonport, advertising in the *Devonport Independent* for a medical officer, in place of the late Dr. W. C. Wilson, deceased, at the rate of 2s. 6d. per member per annum. This is a very antiquated and inadequate sum for such a lodge. For years past good friendly societies have been aiming at giving their medical men at least 4s. a year, and in many cases 6s. We are aware of certain attempts to form huge associations for attending societies en masse and their families at petty rates of 2s. a year. This is thoroughly unworthy of the working classes as well as impolitic. When the wages of the working classes are increasing they should see that the remuneration of medical men for attending them and their families increases too.

### "IN EVERY DEEP A LOWER DEEP."

The modest terms on which the promoters of some dispensaries have been content to attend sick people, or rather to allow their unqualified assistants to attend them, have been exceeded by Mr. Timothy, physician and surgeon, 193, Regent-road, Salford. His fees are stated in a handbill, as follows:—"To meet the working expenses, the charge for each patient will be *siyence*. A visit to any dispensary patient within the radius of one mile will be one shilling."

*Dum Spiro Spero* should refer to the article on Books in our Students' number, Sept. 10th, 1881. Information, brought up to date, will also be found in our forthcoming educational number to be issued on the 9th prox.

*Messrs. Cusson and Co.*—No doubt antiseptics will be employed, though that is a matter which will be left to the discretion of the medical officers. Application should be made to the Director-General of the Army Medical Department.

*L. R. P.*—We are not aware of the existence of an institution of the kind where patients are received at so low a fee.

### "THE CAUSE OR CAUSES OF ACUTE TONSILLITIS."

*To the Editor of THE LANCET.*

SIR,—I had hoped that Dr. Atkinson's letter would have elicited some important information regarding the pathology and treatment of quinsy, an affection which many members of our profession suffer from, owing, I suppose, to the continued mental strain which they have often to endure. Speaking from my own personal experience, I have no hesitation in saying that anxiety is the chief factor in the causation of it. Next to it I would place over-exertion, then chills, irregularity in meals, defective ventilation, &c.

Having had seven attacks, and having consulted some eminent medical gentlemen, the treatment I have been led to adopt is, to say the least of it, very unsatisfactory.—I am, Sir, yours, &c.,  
July 29th, 1882.

TYRO.

*Sig. Loescher.*—The number forwarded will be noticed in due course, but we cannot exchange.

*Dr. Henry Davy.*—The paper will be published very shortly.

### "OBSCURE SKIN DISEASE."

*To the Editor of THE LANCET.*

SIR,—I will not venture to give a diagnostic opinion regarding the above. If "Enquirens" has not prescribed an ointment of chrysophanic acid, he should do so. I have successfully treated both obscure and obstinate cases of skin diseases with it.

I am, Sir, yours truly,

W. S. STYER, L.K. & Q.C.P., and L.R.C.S.I.

Chatterfield, July 29th, 1882.

### "A PIONEER MEDICAL COLLEGE."

THERE is, it appears, in the United States a certain establishment, with a medical title, which issues to the world a printed list of physicians addresses. "The following letter," says the *Philadelphia Medical Times*, "was recently received by this firm, and we give it in full as chronicling a new birth, and as an example of what material is required in this land of freedom for the construction of an institution which gives the right to practise medicine:—

'COLLEGE OF PHYSICIANS AND SURGEONS,

'JOPLIN, MO., 5, 23, 1882.

'GENTS,—Please send price list of Doctors, and Druggist Names, by states as I want to mail several thousand Annual Catalogues to the Profession, all over the U.S.A. and Canada. I am starting an embryonic Pioneer-Medical College and I must, of necessity, noose it around to the world to make it pay me. An early reply will greatly oblige your Respectfully, &c. J. C. PETIT, M.D., Dean."

### DISEASE STATISTICS IN CANADA.

At the recent setting of the Medical Council of the College of Physicians and Surgeons of Ontario, a plan was approved whereby statistics of disease in the Dominion might be collected. The scheme proposed the appointment by the Federal Council of 144 medical practitioners whose duty it should be to report every week upon the diseases most prevalent, their severity, &c., in their respective districts. For this service each reporter is to be paid twenty-five dollars yearly.

### TONGA.

DR. D. L. WALLACE, of Newark, N.J., contributes to the *New York Medical Record* his experiences in the use of tonga. He states that the results of the employment of the drug have in his hands been remarkably good, and he thinks it deserves a place among successful new remedies.

*L.R.O.P. Edit.*—The title mentioned cannot be used in connection with this qualification.

*Mr. Brookhouse.*—Next week.

*Dr. S. C. Smith (Halifax).*—The paper will be inserted in an early number.

### "RECOVERY FROM RABIES."

*To the Editor of THE LANCET.*

SIR,—I have read with special interest your note on Recovery from Rabies. I quite agree with you that to fix the date at which, in cases of recovery, the animal's saliva ceases to be infectious would be a great step in advance. I would suggest, however, that a still more pressing question is the date at which the saliva becomes infectious. A few months since a lay journal stated that if a dog did not show symptoms of rabies within ten days or so after he had bitten a person, the patient was absolutely safe from hydrophobia, for the reason that if the poison was in the dog's system it was either not sufficiently concentrated or not sufficiently active to do harm. I immediately challenged the editor of the paper to produce proofs of his statement, but, though he reiterated it, the required evidence was not forthcoming.

It certainly seems to me a reasonable supposition that canine rabies should have a definite period of incubation, and that the animal should not have the power of imparting the disease till towards the close of that period; but no medical practitioner in this town, as far as I have been able to consult them, can give me any information on the subject whatever, and our leading veterinary surgeon absolutely rejects the statement as untrue.

If you or any of your readers could bring forward any evidence on the point, it would help us to quiet the fears of many a dog-bitten patient.

I am, Sir, your obedient servant,

July 29th, 1882.

A PROVINCIAL HOUSE-SURGEON.

*Hammill* will probably find the information he desires in Dr. Hardwicke's book "On Medical Education and Practice in all parts of the World."

*R. & B.*—No card enclosed.

*Mr. W. A. E. Wilson.*—Six weeks from the time of attack you probably intended, which can hardly be regarded as too wide a limit.

### "THE NEW DECISION UNDER THE REGISTRATION OF DEATHS ACT."

*To the Editor of THE LANCET.*

SIR,—If the decision of Mr. Chance at the Lambeth Police-court is to become law, the coroner's work will be largely increased. I saw a case this week, a very common one in practice among poor people. My diagnosis I think was correct, and my prognosis I know was, as I told the friends there was no hope, although I gave them a bottle of medicine. The following day they came for a certificate of death. According to Mr. Chance's law I am liable to a fine of £2 and £2 2s. costs. I do not intend to run any risks, and the next case I have I shall decline to certify, and bring the matter before the coroner and quote the new law. I am not so sure that he will agree with it.

I think that an immense number of your readers will consider themselves quite justified in giving the usual certificate of death after "one solitary attendance," which Mr. Chance holds does not amount to that degree of investigation and attendance of the patient's case which would warrant such an act.—I am, Sir, your obedient servant,  
August 2nd, 1882.

SPES.

**ERRATA.**—In Dr. Hill's letter on "Stamping out Small-pox," inserted last week, two or three printer's errors escaped correction. In the twenty-eighth line, for "inmate," read *inmates*; in the fortieth line, for "attack," read *attacked*; in the forty-fifth, for "quarantine," read *quarantined*; and in the eightieth, for "circumstance," read *circumstances*.

ON

## PAIN AT THE HEART AND PALPITATION.

Delivered in King's College Hospital,

By I. BURNEY YEO, M.D., F.R.C.P.,

PHYSICIAN TO THE HOSPITAL.

### LECTURE I.

GENTLEMEN,—There are few symptoms that we are more frequently called upon to relieve than pain at the heart and palpitation. In nine cases out of ten, perhaps, these symptoms are referable to dyspeptic conditions or to hysterical states, and a knowledge of this fact has probably at times induced us to pay less attention to them than they have merited. It has occurred to me, therefore, that it would be advantageous to make use of the opportunities we here so largely possess to examine and analyse in detail, more fully, it may be, than has hitherto been done, the precise nature and signification of these symptoms. I shall also take this opportunity of introducing to you a method of exploring the sensibility of the præcordial and præ-aortic regions, which has been suggested and largely applied by Professor Michel Péter of Paris, and which you have seen me adopt in the investigation of several cases in this hospital. My observations, although they confirm in all essential particulars the conclusions advanced by this eminent clinician, do not entirely coincide in all points with his.

I propose, then, in this lecture to direct your attention chiefly to the consideration of cardiac pain, or of pain referred to the cardiac region as its seat. "Pain at the heart," as complained of by patients themselves, is often a very vague term. Pain anywhere in the left side of the chest, and often pain in the epigastric region, are commonly spoken of by the sufferer as "pain at the heart." Usually the complaint of "pain at the heart" means the existence of pain about the anterior part of the chest, on the left side, near the base. Now, it is scarcely necessary I should say that pain in this region may have nothing whatever to do with the heart, yet I have been somewhat surprised, while carrying out the method of exploration I am about to describe to you, to find in how many of the cases where "pain at the heart" has been complained of there has been quite unmistakable tenderness, on pressure with the tip of the finger, over the seat of the apex beat.

Of the different causes of thoracic pain which may incorrectly be referred to the heart as its seat, you must take account of the following:—

1. *Intercostal Rheumatism*: rheumatism of the intercostal muscles.—The pain of intercostal rheumatism is rarely limited to one or two spots: it usually occupies a certain tract of muscular tissue. It occurs with or is aggravated by movements of the chest; it is often relieved by diffused pressure or any support which diminishes thoracic movements. It is often accompanied by muscular pain elsewhere, and the pain is sometimes described as shifting its seat. The patient will generally tell you that he feels it when he stoops or when he straightens himself after stooping, or when he rises from the lying or sitting posture.

2. *Intercostal Neuralgia*.—This is a common affection in women, and is not unfrequently spoken of by them as "pain at the heart," especially when it occurs, as it often does, in the subjects of hysteria, with chronic uterine affections. It usually affects the sixth, seventh, and eighth intercostal nerves. It may generally be recognised by its sharp lancinating character, shooting along the course of the intercostal nerve, and by the discovery of Valleix's points—three painful points along the course of the affected nerve; one of these, the "vertebral" point, situated quite external to the spinous process and opposite the point of emergence of the nerve from the intervertebral foramen; the second, a "lateral" point, situated about the middle of the intercostal space, corresponds with the division of the nerve; and the third, "sternal" or "epigastric," point is found near the sternum, on the upper and about the middle line in the epigastrum, when the lower nerves are affected. It sometimes follows or accompanies an attack of *shingles* (herpes zoster).

3. *Costal Periostitis*, of syphilitic origin.—In such cases there is tenderness on pressure over the ribs and their cartilages, where the periosteum is felt to be thickened, and these pains are aggravated at night, when hot in bed.

4. *Pleuritis*.—The pain of acute dry pleurisy is felt as a peculiar "stitch" or catching pain on inspiration. It is usually attended with some fever, and a friction-sound may be heard on careful auscultation. In cases of chronic progressive phthisis, pains of pleuritic origin are not infrequently spoken of by patients as "pains at the heart." Old *pleuritic adhesions* may also give rise to pain in the side. This may come on after severe exertion of the respiratory organs, as after coughing, or from anything causing unusual traction on these adhesions.

5. The pain and discomfort attending *flatulent distension of the stomach*, associated with acidity and known as "heart-burn," are often, very often, mistaken by patients for cardiac pain, and in this case the action of the heart, too, is often excited, and there is also complaint of palpitation. Under this head I would mention one of the effects of the abuse of tea, coffee, and tobacco. Either of these, but especially tea, will frequently give rise to a form of dyspepsia associated with vague pains in the chest, not always limited to the region of the stomach, but often referred to a spot higher up on the left side of the chest, and commonly accompanied with disturbed cardiac action and a nervous apprehension of the existence of heart disease. I think there can be no doubt that overdoses of tea and coffee do disturb cardiac innervation to a considerable extent, and possibly cause occasionally a certain amount of cardiac neuralgia.

6. Finally, there is a pain usually spoken of as "sub-mammary pain," but constantly referred by the patients themselves to the heart, which you will often hear complained of by young women who are also the subjects of anæmia, or who are suffering from some derangement of the menstrual functions; and you will, moreover, frequently find this submammary pain associated with tenderness over the ovaries, and especially over the left ovary. If you examine these cases attentively you will find that the pain complained of is often limited to a spot situated exactly over the cardiac apex, just over the seat of the apex beat, and it is much aggravated by pressure of the tip of the finger on this spot. I have satisfied myself of this again and again, and I have repeatedly taken occasion to demonstrate this fact. You may press with moderate firmness, with the tip of the finger, on various parts of the surface of the chest without provoking any complaint of pain, but the instant the tip of the finger presses over the seat of the apex beat, the patient starts back with a very decided expression of suffering. What, then, is this submammary pain? Is it, after all, a pain of the heart itself? Is it an anæmic or other hyperæsthetic morbid state of the cardiac muscle or nerves dependent on the general anæmia? or is it a form of cardiac neuralgia sympathetic with a morbid condition of the sexual organs, especially of the left ovary? When it is associated with well-marked anæmia it will certainly disappear completely as the anæmia disappears. But when it is associated with ovarian irritation without anæmia, as you will sometimes find it to be in robust young single women with florid complexions, it is often a most troublesome symptom to relieve. Repeated small flying blisters over the left ovary and over the cardiac apex have appeared to me to be one of the most effective modes of treatment in this latter class of cases.<sup>1</sup>

I have enumerated these several varieties of thoracic pain, any of which may be spoken of by patients themselves as "pain at the heart," to clear the ground, so to speak, for the more exclusive consideration of pain having its origin in some undoubted morbid condition of the heart itself, or of its covering or of the great vessels at its base. And before I proceed to treat of this subject in detail it will be necessary for me to describe to you the method of exploring the cardiac

<sup>1</sup> I notice that Dr. Balfour, in the second edition of his excellent lectures on Diseases of the Heart, which I have only just had an opportunity of seeing, modifies the statement which appeared in the first edition as to the nature of this submammary pain, and adopts a view almost identical with the one I have stated in my lecture. In the first edition he speaks of this pain as "wholly external," but in the second edition he modifies this as follows:—"In some cases the infra-mammary pain is wholly external. In most, however, the pain is truly cardiac in character." And further on he says, "The infra-mammary pain of chlorotic girls is almost invariably associated with pain in the heart itself, neurotic in character, and depending on mal-nutrition."

sensibility, for the introduction of which we are indebted to Professor Péter of Paris. Dr. Péter considers this method of examination of equal importance with that of auscultation or percussion. You must bear in mind that the cardiac muscle in the healthy state is insensible. Even in wounds of the heart pain is a very rare symptom, and it has been observed that when the heart has been touched by foreign objects passed through a wound in the chest pain has rarely been felt. Harvey had the opportunity of making some observations on the Duke of Montgomery, whose heart was partially exposed, after the healing of a severe wound of the chest, and he convinced himself that the heart in a healthy state was entirely wanting in sensibility.

But it is not only the sensibility of the cardiac muscle and its ganglion which we profess to expose by this method, but also that of the nerves of the cardiac plexus, and of portions of the pneumogastric and phrenic nerves. The method I am speaking of consists in simply pressing with the tip of the index finger, and with moderate force, along the intercostal spaces corresponding with the præcordial and præ-aortic regions, and generally on the several points in the thoracic and cervical regions which are in relation with the organs whose sensibility we wish to explore. Patients who suffer from chronic myocarditis often complain of a dull, heavy, almost constant deep-seated pain in the region of the heart, aggravated at times under the influence of emotion or any considerable effort, and shooting then into the back. In such cases pressure with the tip of the finger along the intercostal spaces in the præcordial region, close to the sternum and over the ventricle, will constantly afford distinct evidence of the existence of a morbid sensibility of the cardiac muscle. The patient will often complain of severe pain when pressure is made over certain definite spots. In these cases the pain is especially felt in the fourth and fifth left interspaces when the surface of the ventricle is in contact with the wall of the chest, and also over the cardiac apex. And pressure over the apex will remain painful even after the pain has disappeared, under suitable treatment, from the other points.

Dr. Péter has noticed that in middle-aged men who suffer from the excessive abuse of tobacco, pressure over a very limited point on the third left intercostal space, near the sternum, will give rise to acute pain; and he thinks this point corresponds with the auriculo-ventricular groove, and that this strictly localised pain is probably due to a morbid condition of the ganglion of Remak consequent on tobacco impregnation. Such patients often suffer from cardiac intermissions, of which they are conscious, and also from deep-seated pain, which they refer to the same spot, which is found to be painful on pressure. In morbid affections of the aorta and its valves he finds pain on pressure over the second left intercostal space close to the sternum and over the sternum itself on the same level; and this pain he maintains is due not to the lesion of the aorta itself, but to a neuritis propagated from the diseased aortic tunics to the nerves in close relation with that vessel.

Pressure over the præ-aortic region is also of special importance in exploring the sensibility of the cardiac plexus and its tributary nerves; but it is necessary to be careful not to press too strongly over this region, as an attack of angina has been induced by neglecting this precaution. If there exist neuritis or neuralgia of this plexus, then pain on pressure with the tip of the finger will be found either in the third, second, or first left intercostal space near the sternum, or over the sternum at the level of the second interspace. The second intercostal space, a few lines from the left border of the sternum, has been found by Dr. Péter to be particularly painful on pressure in these cases as well as over the sternum in this level; and he mentions that pain in this situation is very significant of lesion of the aorta affecting the whole thickness of its walls, since the nerves adherent to them are involved; and he asserts that he has often been able by this method of exploration to diagnose the existence of aortic disease which had not been before suspected.

In such cases Dr. Péter has found, and, I believe, been able in several cases to corroborate his statement to a certain extent, that there is tenderness on pressure over the pneumogastric at the root of the neck, especially on the left side, and in other parts of its course. I have several times found a painful spot on pressure with the tip of the finger over the situation of the vagus (just at the root of the neck, inside the anterior border of the sterno-mastoid); but I have not been able to corroborate Professor Péter's observation as to the existence of painful spots in these cases over the spines of

the upper cervical vertebrae. Nor have I been able to satisfy myself that it is easy (as Dr. Péter seems to think) to explore in this manner the condition of the phrenic nerves.

I will now ask you to allow me to bring before you the particulars of a certain number of cases where the patients have complained of "pain at the heart," and where exploration of the sensibility of the cardiac muscles and nerves, in the manner I have just described, has given definite results. In many of these cases there was evident organic valvular lesion, readily detected by the ordinary methods of examination; but in some other cases there was no organic valvular disease to be discovered. And first let me call your attention to those cases of organic cardiac lesion in which the complaint of cardiac pain has been a marked feature. I am not at this moment thinking of those alarming paroxysmal attacks of pain often observed in persons where no definite cardiac lesion has been detected, and called usually by the name of "angina pectoris." We shall certainly have to consider briefly these cases in connexion with our present subject, because I cannot doubt that causally they are often closely allied with the non-paroxysmal form of cardiac pain. But I wish, in the first place, to speak of that less severe and less distinctly paroxysmal form of cardiac pain found associated with many cases of heart disease.

Now, there is one clinical fact you may accept undoubtedly, and that is that complaint of cardiac pain is much less common in mitral than in aortic disease; and the reason probably is that in many of these cases of disease of the aortic valves, there is associated with it a diseased condition of the coats of the aorta, a chronic aortitis, which extends to

FIG. 1.

and invades the contiguous nerves of the cardiac plexus. I am speaking, of course, of cardiac pain of some intensity, not of mere cardiac discomfort, which is common enough in mitral cases. I will now read to you from my case-book the notes of one of the first cases in which I applied this method of cardiac exploration, and in which the complaint of "pain at the heart" was well founded, was associated with well-marked lesion of the aortic valves, and moreover was greatly benefited by appropriate treatment.

J. A—, aged thirty-nine, a labourer, applied at the Brompton Hospital last spring, complaining of pain at the heart, shooting through the left breast to the back, and also of sudden pains across the chest, which made him stop when walking. He also complained of "fluttering at the heart." He had been troubled with this pain, together with some dyspnoea, cough, and streaky expectorations for seven or eight weeks. He had also lost flesh; had had rheumatic fever four times. There was notable pallor of the face and lips. Examination of the heart revealed the existence of a prolonged systolic murmur at the base, loudest over the second right cartilage, but conducted all over the cardiac region. There was some hypertrophy of the ventricle and some dulness over the base in the upper sternal region, as if from dilatation of the aorta. Pulse 104, rather small. On pressure with the tip of the finger over various parts of the chest three distinctly painful spots were discoverable—one at the sternal end of the first, one at the sternal end of the second right interspace, and the third at the sternal end of the third left interspace. He was ordered four minims of tincture of digitalis in one ounce of the iron and calumba mixture of the Brompton Pharmacopoeia three times a day, and to apply small flying blisters the size of a florin over the

upper sternal and adjacent præ-aortic region. A fortnight afterwards he reported himself as much better; he had less pain and less dyspnoea. Pulse had fallen to 88. Under this treatment the pain continued to get less and his dyspnoea was greatly relieved, and the pulse became stronger and less frequent. The annexed diagram shows the situation of the painful points in this case. (Fig. 1.)

In this case the affection of the aorta was no doubt of rheumatic origin, and the chronic inflammatory condition of the coats of this vessel had probably extended to some of the nerves of the cardiac plexus in relation with it. There appeared to be some want of tone about the cardiac muscle and imperfect filling of the vessels, though no regurgitant murmur could be detected. Great benefit followed counter-irritation over the aortic region, associated with small doses of digitalis and citrate of iron.

The next case to which I wish to call your attention also illustrates the value of local and general treatment in relieving the cardiac pain and other symptoms dependent on aortic disease.

This patient, a widow, thirty-two years of age, engaged in teaching, I first saw in November, 1876. She was not, at that time, complaining especially of cardiac pain, but of dyspnoea on exertion, of cough, of frequent epistaxis (six years before she had had a small hæmoptysis), and of loss of appetite and constipation. She then had a diastolic murmur, heard loudest in the mid-sternal region at the left border of that bone. There was no history of acute rheumatism. I saw her once or twice during the next two years. But in the spring of 1880 she came to see me complaining for the first time of "pain at the heart." She was said to be suffering from the shock of the death of a sister, and complained of much nervous distress and of sleeplessness. She had a cough, and the expectoration was often tinged with blood. But her chief complaint was of pain in the cardiac region, shooting down both arms to the elbows, aggravated on the least exertion. She came to see me again in May, 1881, with much the same symptoms, pain at the heart and palpitation, pain shooting down left arm from shoulder to elbow, some swelling of the ankles, which she said "turned black" at times; dizziness, ringing in ears, loss of appetite, and constipation. As before, there was a distinct "brush-like" diastolic murmur in the mid-sternal region; the apex beat was somewhat diffused, but in its normal situation. Pulse 120, collapsing. On exploring the cardiac sensibility with the tip of the finger, one, and only one, painful spot was found at the sternal end of the second left interspace. There was marked tenderness over this spot, and pressure there with the tip of the finger provoked an immediate complaint of pain. She was ordered a mixture containing five-minim doses of tincture of digitalis with five grains of citrate of iron, some ammonia and chloric ether. A small flying blister was to be repeatedly applied to the præ-aortic region. Three weeks after the commencement of this treatment she was very much better; the pain in the cardiac region and in the left arm was much less; the palpitation was less troublesome, and the pulse was reduced from 120 to 80; moreover, the painful spot in the second left interspace had disappeared.

(To be concluded.)

## ON THE ABORTIVE TREATMENT OF GONORRHOEA.

By W. WATSON CHEYNE, M.B., F.R.C.S.,

ASSISTANT-SURGEON TO KING'S COLLEGE HOSPITAL, AND DEMONSTRATOR  
OF SURGERY IN KING'S COLLEGE.

(Concluded from p. 177.)

I WILL now proceed to give my experience in hospital practice since October, 1880, and then I will sum up the facts, and describe what I believe to be the best mode of procedure. The method which I originally tried was the introduction of one of the bougies previously described, followed by the use of an injection of boracic lotion, and the administration of alkalies and aperients. After some time, I tried an emulsion of eucalyptus oil as an injection (one part of the oil in forty parts of the emulsion), and certainly got more rapid cures. The results obtained in about forty cases by these means are detailed in my former paper. At the commencement of the period at which this statement of results begins, I con-

tinued to treat patients in the acute stage by the insertion of an iodoform and eucalyptus bougie, the frequent use of an injection of eucalyptus emulsion, and the administration of alkalies and aperients. I treated nine cases in this way during the winter of 1880. Of these, six were seen within five days of the commencement of the discharge, and in all the inflammation was cut short at once, and the average duration of treatment till complete cessation of all discharge was nine days and two-thirds. Two were not seen till fourteen days after the commencement of the disease, when the acute symptoms had almost subsided and the duration of treatment in these was twelve and twenty-eight days respectively, so that here the treatment cannot be said to have had any influence in arresting the disease; this is in accordance with my general experience. The other case was a patient suffering from gleet, who contracted a gonorrhoea eight days before he was seen. The inflammatory symptoms subsided under treatment, and in three or four days he was in the same condition as formerly—i.e., he had a little gleet discharge, noticed the first thing in the morning. I soon found that copaiba might also be given with great advantage from the very first, and two cases were treated with an iodoform and eucalyptus rod, and copaiba and eucalyptus injection, the one being well in four days, and the other in fourteen days. In the latter there was only a little discharge in the morning after the fifth day, but it did not entirely disappear till the fourteenth day. In two cases the use of an injection of eucalyptus emulsion, and the administration of an alkali, without the previous introduction of an iodoform and eucalyptus rod, did not appear to shorten the progress of the disease.

Several patients having complained of the irritating nature of the eucalyptus injection, and the pain caused by it, I began to try other injections, and, finally, the following case led me to abandon the eucalyptus emulsion altogether. A patient treated with the bougie and the emulsion got almost well in four or five days. He complained, however, of the pain caused by the injection, and after about four days the discharge increased, and an abscess formed in the cellular tissue of his penis. Of course abscess is not an unfrequent complication of acute gonorrhoea, but here the acute inflammatory stage had apparently been checked, and I cannot but attribute the abscess to the irritating nature of the eucalyptus injection. Among other substances which I tried, I used the injection of tannin—two grains to the ounce of water. In four patients in whom this was employed the average duration of treatment was nine days and a half, but one of these cases was eighteen days in getting quite well, though after five days there was only a little discharge in the morning, and thus the average time required for complete cure is considerably increased. These patients, however, also complained of the pain caused by the injection, and one case had symptoms of irritability of the bladder for some days. I finally tried, and now always use, an injection of sulpho-carbolate of zinc (two grains to the ounce of water), begun after the introduction of one or two of the iodoform and eucalyptus rods, copaiba being at the same time administered internally. The following is the mode in which I proceed:—The patient is told to pass his water; he then lies down, and an iodoform and eucalyptus rod is dipped in eucalyptus oil, and passed into the urethra; a small pad of boracic lint is applied over the orifice, outside this a large piece of gatta-percha tiasna, the whole being fastened on by strapping. He is told to allow this to remain on as long as he can, generally about five or six hours. He then takes it off, passes water, injects one or two syringefuls of the sulpho-carbolate solution, and if the case is very acute another rod is introduced. Afterwards he uses the sulpho-carbolate of zinc injection as often as he can (six or seven times a day generally), always passing water before its use in case any infective material remains in the urethra, which might be driven back before the injection. I always recommend that a piece of boracic lint be kept over the orifice of the penis to absorb the discharge; this can be retained in position by drawing the prepice down over it. A purge is administered at the first, and the bowels are afterwards kept freely open by salines. Copaiba is also given in half-drachm doses thrice daily from the beginning. The patient is further cautioned against the use of beer or spirituous liquors, &c. After three or four days, when the acute symptoms have subsided, an injection of sulphate of zinc, tannin, acetate of zinc, or, indeed, any of the astringent injections in common use, is substituted for the sulpho-carbolate, which, in my experience, though the best injection

at the beginning, does not, as a rule, arrest the discharge in the chronic stage nearly so rapidly as some of the other injections. After the discharge has ceased the injection, and possibly, also, the copaiba, at any rate the restrictions as to drink, ought to be continued for four or five days, so as to avoid a recurrence of the discharge.

Fifty-one hospital cases were treated more or less in the way described with the following results. In forty-one the average time from the commencement of the treatment till complete cessation of the discharge was 9.9 days. Of these four cases lasted longer than fourteen days, being eighteen, twenty-six, twenty-eight, and thirty days respectively under treatment; in all the acute symptoms had completely subsided in two or three days, but a little discharge remained, especially seen in the morning, which did not quite disappear till the times mentioned. In two of the four cases the sulpho-carbolate injection was unintentionally continued throughout; and I think this may have had something to do with the result, though it is undoubted that in some people, for some reason which is not very apparent, the discharge does not cease so quickly as in others. In two cases the discharge returned slightly after heavy drinking, but soon got well again; and in two cases it returned for a day or two after leaving off the injection, but disappeared again under treatment. The average time which had elapsed between the onset of the symptoms and the commencement of the treatment was 3.2 days. It may be interesting to state the time more exactly; thus in seven the symptoms had lasted for one day, in twelve for two days, in eight for three days, in five for four days, in three for five days, in one for six days, in four for seven days, and in one for eight days. The incubation period of the disease also varied considerably, having an average of 4.5 days in thirty-nine of the cases (in two the incubation period was not ascertained). More exactly, three had an incubation period of one day, three of two days, ten of three days, four of four days, seven of five days, five of six days, three of seven days, two of eight days, and two of ten days. As far as possible only cases of virulent gonorrhoea are included in this list, though in the cases in which the symptoms had only lasted for one day it was not always easy to be certain that a virulent attack was coming on. However, even in these rapid increase in the amount of discharge, increase in the scalding pain on passing water, and in some marked redness of the orifice of the urethra and of the glans penis indicated pretty certainly a severe attack. The majority of these were first gonorrhoeas. The other ten cases require special notice. In one the sulpho-carbolate of zinc injection was used throughout, and not at all regularly. Here the acute symptoms subsided as usual, but the discharge did not cease absolutely till the twenty-second day. In two instances the patients did not come back for a fortnight, not having had medicine or injection for a week. These got well in twenty and twenty-two days respectively. In one case where the symptoms were acute they subsided on the commencement of treatment, but a slight gleet discharge continued for three months. Six weeks after the commencement of the discharge a secondary syphilitic eruption appeared. The patient was positive that he had never had anything the matter with him before. No chancre, no gonorrhoea, no syphilitic symptoms. Was this a case of chancre in the urethra as well as of gonorrhoea, and was the gonorrhoea cured, and did the chancre remain? I could not make out any swelling in the urethra, and I regret that I have omitted to note the incubation period, but I think it was only a few days. In two cases though acute symptoms subsided rapidly, as usual a gleet discharge remained for about two months, and one of these had symptoms of irritability of the bladder, and the other had had chordee, though the inflammatory stage had passed off. (It is a curious fact which I cannot explain that in one or two cases where the discharge had almost or entirely ceased erections of the penis, sometimes painful, were troublesome about the eighth or tenth day.) In one case the acute symptoms subsided and the discharge steadily diminished till the fifth day, when being ill from some other cause the patient ceased the treatment and the discharge increased; slight scalding returned. He had symptoms of irritability of the bladder. He was, however, quite well fourteen days later, the treatment thus lasting nineteen days. One case was that of a married man who had apparently not been infected with gonorrhoeal pus. The symptoms were acute, and were checked as usual, but the discharge only ceased after a month's treatment. In one no benefit was derived from the treatment, the acute

symptoms were apparently unaffected, and the case followed the usual course, two months elapsing before the cure was complete. In one case the injection and copaiba were never used, only the bougie being employed, and there was only slight improvement as the result. This case lasted five weeks. This last case brings me to one or two experiments which I made with the view of testing what part each of these three things—the iodoform and eucalyptus rod, the injection of sulpho-carbolate of zinc, and the copaiba—took in the treatment, and whether their conjunction was really necessary.

In another case I have used one bougie alone, without any other treatment, and though the acute symptoms were checked to some extent they did not subside so rapidly as usual. In three cases, two of them not very acute, the sulpho-carbolate of zinc injection and copaiba were used alone, the treatment being begun four, six, and seven days after the commencement of the disease, and an average of twenty days was required for complete cure. The use of a bougie and the sulpho-carbolate injection cut short the acute symptoms much as usual in two cases, but they were not quite well for sixteen days. The essentials for cutting short the acute stage seem to be the introduction of one or two iodoform and eucalyptus rods and the use of an injection of sulpho-carbolate of zinc, while the copaiba and the substitution later on of some other astringent for the sulpho-carbolate shorten the treatment very considerably.

Alongside of these cases I have treated a number with alkalies, diuretics, purges, &c., without any local treatment in the first instance. The contrast in the results was very striking; for while those treated locally came back in four days or a week, saying that the acute symptoms had passed off in two or three days, and that the discharge had either ceased or was very slight, those treated in the ordinary way generally said that the acute symptoms were but slightly better, indeed sometimes worse, and that the discharge was more profuse, while complications occurred not unfrequently. The absence of complications in the cases treated by the method which I have been describing is very gratifying, while one does not have those bugbears of an out-patient room—cases which come week after week complaining of a little discharge in the morning.

When Dr. Koch was in London at the meeting of the Congress in 1881, I spoke to him on the subject, and told him about my attempts to arrest gonorrhoea. He suggested that I might get still better results if I used bichloride of mercury, which was the most powerful antiseptic with which he was acquainted. I accordingly introduced into each iodoform and eucalyptus bougie one-sixteenth of a grain of bichloride of mercury, and have used these bougies in eleven cases, the rest of the treatment being carried out in the same way as before described. The result, however, did not show any improvement on my former plan; indeed, I think rather the reverse. The average duration of treatment in ten of these cases was ten days and a half; but this average is increased by two cases, which lasted for eighteen days. In one case the treatment failed, and the patient was only well after six weeks. All the patients complained of considerable pain for a short time after the introduction of the bougie; in some, indeed, the pain was severe. There were no complications in these cases, but as I found no advantage from the bichloride of mercury, and as there was greater pain caused, I have given up its use. In three cases I tried weak injections of bichloride of mercury, one grain to ten or twelve ounces of water. Only one of these cases was a typical acute gonorrhoea, and this did not improve materially as a result of the treatment, and was not well till eight weeks had elapsed. In the other two cases there were no acute symptoms, and these got well in about twelve days. I do not think that the use of injections of bichloride of mercury is a promising method of treatment.

Since I began these experiments I have become acquainted with another method of arresting gonorrhoea. Mr. Furneaux Jordan of Birmingham, in speaking of the good effects of counter-irritation in the cure of acute inflammations ("Surgical Inquiries") mentions two or three cases in which very rapid cure of gonorrhoea has resulted from the application of blisters in the groin. He tells me that the results of this method vary in different individuals, but that in first gonorrhoeas it is generally satisfactory. In later attacks of gonorrhoea, and more especially where there is a tendency to stricture, however slight, the treatment is ineffectual. Now, it may be objected that if this inflammation can be

arrested by counter-irritation in the groin it cannot be caused by the growth of organisms in the urethra. In answer to that I would remind the reader that from the very first I have looked on two factors as necessary—namely, organisms and a weakened condition of the mucous membrane. The organisms weaken and inflame the mucous membrane in their vicinity, and then grow in it and affect the neighbouring parts similarly. If, however, that mucous membrane be brought into a condition in which it cannot inflame, as we may roughly suppose to be the effect of efficient counter-irritation, then the organisms cannot spread, and if this condition of the mucous membrane be kept up they must ultimately die out. Hence I would conclude that it is quite possible that counter-irritation might check, and even cure, the inflammation, but then it must be kept up for some time after the discharge has ceased, otherwise the organisms will again grow. I wrote to Mr. Jordan to ascertain if this were the fact, and he tells me that it is, and that if the counter-irritation be stopped too soon the gonorrhœa returns. Now, seeing the effect of counter-irritation, if we add it to the treatment I have proposed, and thus destroy the organisms, we ought to have a more rapid and perfect result. It is but seldom that one can get a patient who is able to lie in bed for some days, and I have only once in a first gonorrhœa tried counter-irritation on Jordan's plan, but without any good result. I should however, if opportunity presented, try the combination of the two methods as just mentioned.

I may sum up the results of this investigation shortly as follows:—The treatment recommended here—the use of one or two iodoform and eucalyptus rods, an injection of sulpho-carbolate of zinc, and the internal administration of copaiba—has the effect, in the great majority of cases of acute gonorrhœa, of checking the acute symptoms in a day or two, and bringing the disease rapidly to the chronic stage, thus avoiding all the risks dependent on the violence of the inflammation. The discharge at this time is very amenable to treatment, and gets rapidly well under the use of suitable remedies. All that I claim for the method, however, is that it cuts short the acute stage, in the great majority of cases, and thus the patient escapes the dangers and pain incident to that stage. The essential parts of the method are the use of the bougie and the injection; but the rapidity of cure is much aided by commencing the use of copaiba or sandal oil at once. The method may be employed at any stage of the disease, but is, in my experience, only of use before or during the acute stage, up to (say) the eighth day. The result is the more marked the more acute the inflammation, the rapid subsidence of the inflammatory symptoms being very striking. Even in the very few cases in which it has failed to produce this effect, it has not, so far as I can judge, done any harm. The addition of bichloride of mercury, though a powerful antiseptic, to the rod, or its use in the form of injection, does not seem to be of advantage. It is possible that the combination of counter-irritation with this method may yield even more rapid and satisfactory results.

[ERRATUM.—In the last paragraph but one of last week's issue for "granting, however, that these views are incorrect," read "granting, however, that these views are correct."]

Old Cavendish-street, W.

## A CASE OF HYDROPHOBIA TREATED SUCCESSFULLY WITH ACONITE.

By D. H. CULLIMORE, F.R.C.S.I., &c.,

PHYSICIAN TO THE NORTH-WEST LONDON HOSPITAL; FORMERLY ON  
THE MEDICAL STAFF, H.M. INDIAN ARMY.

THE rapid approach of the dog days, and the recent report from Paris of a successful case of hydrophobia treated with pilocarpine, induce me to publish the notes of the following case, where aconite—a drug possessing properties in some respects analogous to jaborandi—was the chief remedy employed.

A boy, aged ten years, presented himself at the out-patient department of the North-West London Hospital, complaining of pain over the diaphragm and abdomen, with gasping and spasmodic breathing. Some three weeks before

he was bitten on the finger by a supposed rabid dog; but as the wound after cauterisation healed well, and as he continued in his usual health, no notice was taken of him till two days before he was taken to the hospital. At this time, however, owing to the wound becoming painful and angry-looking, and symptoms such as restlessness, anxiety, fidgetiness, and sleeplessness having commenced to trouble him, relief was sought. The boy was admitted an in-patient on November 13th, 1881, as, in addition to the symptoms just detailed, there was a peculiar and suspicious wildness of expression, with choreic-like twitches of the face, and a temperature of 101° F. These symptoms, taken in their entirety, led me to so strongly suspect the existence of the melancholic stage of hydrophobia that I fully expected the immediate onset of the fully developed symptoms of this dreaded disease. The tongue was furred and cracked in the centre, but red at the tip and edges, and the pulse presented nothing abnormal.

The treatment, after placing the patient in a quiet and secluded corner, consisted of a dietary of milk thickened with arrowroot and beef, with the following mixture:—One minim of the tincture of aconite, six grains of bromide of potassium, six minims of the tincture of cinchona, to half an ounce of water, to be taken every half hour for twelve doses, and then three times a day.

Jan. 16th: Passed a restless night, attended with occasional delirium till towards morning, when very free perspiration was followed by sleep. The sister in charge states positively that he refused to take fluids during the night, and, on testing him myself, he took water with reluctance, swallowing it, however, with about the same difficulty one might expect in a sharp attack of tonsillitis. So much was I struck with this symptom that I at once expected some severe throat inflammation; but on examination no swelling whatever was found, nothing, in fact, beyond a slight redness of the parts about the root of the tongue. It is necessary to say that there was not the same difficulty with the beef-tea and arrowroot, to which thickened fluids his drink was restricted, as I did not think it advisable again to try him with water, lest it might aggravate his complaint. —17th: Continues to complain of the epigastric pain and depression, to which is added severe frontal headache, and is much in the same state as yesterday. He takes beef-tea, and has no convulsive paroxysm beyond an occasional twitch. —19th: The patient has lost his wildness of expression, but appears sleepy and drowsy, owing probably to the effect of the medicine. The wound does not heal well. —25th: He made good progress since last observation; all symptoms clearing up, with the exception of the abdominal sinking, and the state of the wound, which shows little inclination to cicatrise. The aconite to be omitted, and two grains of quinine to be taken three times a day. —27th: The temperature, which for some time was normal, rose to 101° F.; but from this date till December 6th, 1882, it gradually declined. Bowels rather constipated throughout. He was then discharged; temperature normal; wound not well cicatrised.

Remarks.—This case presents two problems for solution:—First, was it a case of hydrophobia, looking at this affection as the result of a specific poison, and not, as some few still consider it, a complex neurosis acting on susceptible organisations? Second, looking at it as an example of the incipient stage of specific disease, did the remedies employed prevent its further and fatal development? The history of the bite and its seat, the period of incubation, and the age of the patient (nine out of thirty-six persons attacked, according to Mr. Dolan, being about this age), together with the renewed pain and soreness in the wound, would render a diagnosis of rabies probable. Added to which, the convulsive twitches, the look of alarm, the fidgetiness, the spasmodic breathing, and the reluctance, difficulty, and refusal to take water, though not insurmountable on the day after admission, and of short duration, appear to me to afford evidence sufficient to render certain what the prodromata rendered probable. Moreover, the absence of other causes, though carefully looked for, corroborates this view of the case. It might be alleged that the difficulty with fluids was of too transient a character to be compatible with rabies, and I grant I was very agreeably and extremely surprised by its speedy subsidence. Yet, on the other hand, many fatal cases are recorded where there was no hydrophobia (using the word etymologically) and no difficulty of swallowing fluids, while it should also be borne in mind that fluid dysphagia is a symptom of other affections, and that

there is at least one case on record where a patient suffering from laryngitis was violently and fatally treated for rabies. Again, if not rabies, what was the disease? Tetanus it certainly was not, for I have seen so many cases of this disease in India that I can positively say the symptoms are very different. Besides, the onset of traumatic tetanus is rarely delayed beyond the tenth day, and never for three weeks. Against the symptoms being caused by serious apprehension and dread of impending evil are the age of the patient and the increase of temperature of the body. The second question to be answered has reference to the value of the medicine. Now, rabies has two stages, exclusive of the period of incubation. One corresponds to the circulation of the poison in the blood, and is reflected by the malaise, fidgetiness, nervous breathing, changes in the wound, and, in this case at all events, by the pyrexia. The other is due to a later pathological action of the poisoned blood setting up irritation of the medulla and the nuclei of the bulbar nerves, and manifests itself by the fatal spasmodic convulsions of the pharynx and air passages. Therefore the remedy should be selected with a double object: first, to eliminate the poison from the blood, and, second, to counteract, control, or relieve the congestion of the nerve centres before referred to. Aconite, as I will now endeavour to show, recommends itself to our consideration as fulfilling both requirements in a manner unequalled by any other drug in our possession, or by any that has hitherto been tried as a remedy for hydrophobia. Thus, by the profuse perspiration which it causes, it eliminates, in common with jaborandi, the morbid poison from the blood. It is true, it does not act as a sialogogue, but no superior benefits can be claimed for jaborandi on this account; as in the olden days mercury to salivation was frequently tried, not only with no good result, but often with an unnecessarily disagreeable one. Thus, it is the sweating action of aconite, as it is of jaborandi, that is beneficial in the first stage. We know that many bitten on exposed parts by dogs undeniably mad never catch the disease, and we know also that the poison may remain permanently latent, or latent till called into activity by some exciting cause, generally of a moral nature. Therefore it is easy to go a step further and conceive how in certain mild cases, but when the latent poison has yet become sensible, it may be removed by such remedial agents as the Turkish bath, aconite, and jaborandi. But the rôle of aconite does not end here, while that of jaborandi and the vapour bath may be said to do so. For this drug, as a vascular depressant, slows the circulation, and thus reduces the interchange between the morbid blood and those tissues on whose irritation depends the fatal manifestations of the disease, "bleeding"—as Dr. Fothergill expresses it, I think, "the blood in its own vessels." And even when this irritation has occurred aconite promptly given is not only the best drug to control it, but, by its great power of subduing peripheral hyperæsthesia, it will reduce to a minimum the effect of those secondary external causes which often bring about the paroxysms and give them their fatal virulence. To substantiate what I have just said, I cannot do better than quote a few examples from Dr. Ringer's text-book. He says that one drop of tincture of aconite given at bedtime quiets the distressing fidgets of men and women, and causes calm and refreshing sleep. The import of this is obvious when we remember that fidgetiness is one of the commonest and earliest symptoms of rabies. The same author says it soothes the nervous system, and favours sleep by producing free perspiration, which perspiration may continue for days, and that it cuts short the inflammation, not by removing its products, but, by controlling the inflammation, it will prevent their formation. In its action on the nervous system Leigois and Hotot state that it paralyses first the perceptive centres, afterwards their terminations, and, lastly, the trunks of the sensory nerves. Thus I am justified in saying that if jaborandi is useful in the first stage of hydrophobia, and wourali, by its soporific and paralyzing effect in the second, aconite, combining in itself the properties of those agents so highly spoken of, is beneficial in both. It might, of course, be combined with one or other, and should also be given as a prophylactic, as indicated by its sedative action, to all who may unfortunately be bitten by animals about whose condition there is the slightest suspicion. Belladonna has been tried and recommended in rabies, which I allude to simply to condemn, for in doses one would be inclined to employ in a disease like rabies, it would probably arrest the action of the skin and cause dryness of the throat and set up convulsions, conditions which it should be our principal aim to prevent.

ON A CASE OF  
OBSTRUCTION OF BOWEL CAUSED BY A  
LARGE INTESTINAL CONCRETION;  
ENTEROTOMY; DEATH.

By J. O. BROOKHOUSE, M.D., M.R.C.P. LOND.,  
PHYSICIAN TO THE NOTTINGHAM GENERAL HOSPITAL.

THE following is a case of such rarity that I venture to hope a place may be found for it in the pages of THE LANCET.

I was sent for on Tuesday, March 14th, to see Mrs. C—, aged fifty-six, the wife of a nurseryman, residing a few miles from Nottingham, from whom I obtained the following history:—On the previous Saturday night she went to bed as usual about ten o'clock, having felt during the afternoon and evening griping, twinging pains in her belly. At three o'clock on Sunday morning she awoke and was violently sick, the abdominal griping and sickness continuing the whole of Sunday, Monday, and Tuesday; when I saw her about 4 P.M. I found her in bed with an anxious expression; cool, dewy skin; small pulse, 88; tongue moist and red, with a yellowish fur in the centre. There had been no action of the bowels since the previous Friday morning. The sickness and retching were incessant. The vomit shown to me was a greenish fluid without odour, and was obviously bile largely diluted with soda-water, of which she drank freely and eagerly. No food had been taken since Saturday evening. The abdomen was not distended (the abdominal wall was very fat and ponderous); there was tenderness on pressure, as well as a distinct tumour to be felt in the right inguinal region (upper border). I at once gave her a large enema—about half a gallon of warm water—which had the effect of removing a considerable quantity of rather light-coloured faeces. I then prescribed two calomel and colocynth pills, to be followed by a draught containing two drachms of the sulphate of magnesia, and two ounces of the compound decoction of aloes, but before leaving the house I gave a quarter of a grain of morphia hypodermically, and further ordered half a grain of opium in pill every four hours. On the 15th at 10.30 A.M. I saw her again; the vomiting continued, the medicines and everything else being instantly rejected; no action of the bowels. I gave another large enema of soap-and-water, but without result. I repeated the hypodermic injection of morphia, and ordered the opium pills to be continued.

The same evening I saw her again and found her condition practically unaltered. I gave an enema of nearly a gallon of thin gruel with an ounce of castor oil and turpentine, and it was returned in a few minutes without a trace of feculent matter. The sickness being so incessant and distressing, and the patient thinking the opium pill added to her trouble, it was agreed to discontinue it until the morning at least, but I gave her another quarter of a grain of morphia by the skin. The vomit presented the same character as before. The size of the abdominal tumour appeared to me to be less, and the local tenderness was, if anything, diminished; on the other hand, her general aspect and constitutional condition were not so good. This was a curious and unusual feature, and I shall refer to it again later.

On the 16th no improvement whatever was observable; one sample of the vomit was brown and had a slightly fecal odour. A large warm-water enema was now given through a stomach-pump tube passed eight or nine inches, but the water returned unaltered. The morphia injection was repeated, and she was urged to take the opium pill every four or six hours. At this morning's visit I first noticed an intermission in the pulse, but the rate was unchanged. The woman was evidently weaker. On the 17th the condition of the patient was unchanged, except that it was clear the exhaustion was increasing and she was becoming apathetic. I mentioned at this visit that I thought medicine would be unavailing, and that next day if unrelieved I should advise an operation. I saw the patient at 10 A.M. on the 18th. She was distinctly more feeble; the pulse smaller and weaker, intermitting every fifteen or twenty beats; facial aspect very unfavourable; eyes sunken; nose pinched; cheeks purple flush. The skin was cool and clammy, the hands and every part of the body rapidly losing

heat on exposure. The sickness was as urgent as ever, and I was shown a vomit ejected during the night markedly stercoraceous in character. I now advised the expediency of operation, and obtained the consent of the patient and her friends. In the afternoon I asked my friend and surgical colleague, Mr. Littlewood, to see the patient with me with the view to an abdominal section. Mr. Anderson, our able house-surgeon at the infirmary, accompanying us to give the anæsthetic. The operation was performed by Mr. Littlewood at 4.30 P.M. by an incision in the median line about four inches in length between umbilicus and pubes. The subcutaneous fat was nearly three inches thick. On opening the peritoneum and introducing the hand in the direction of the right iliac region a hard body was felt within a portion of the small intestine; this on being brought outside the wound was found completely filling, indeed distending, the gut, so that the wall was sufficiently thin to see the nearly black colour of the foreign body, and which was thought to be a gall-stone. An incision was made upon it, when it readily slipped out; the bowel was empty both above and below. The wound was closed with an uninterrupted silk thread and returned into the abdomen. The abdominal wound was united with silk ligatures—treated, indeed, as in the operation for the removal of ovarian disease. The woman was put back into bed and a quarter of a grain of morphia given by the skin. The temperature immediately before the operation was 96° F.; the pulse 88 and intermittent. Ordered not to have anything except soda-water and milk, the quantity of the latter not to exceed a teacupful before the morning. Ice to suck *ad lib*.

The foreign body removed was in shape and size very similar to a small hen's egg, its weight, two hours after removal, was eight drachms less fourteen grains, its circumference at its upper or broad end was three inches and seven-eighths, at the narrow end barely three inches and a half, whilst its length was two inches and a half; it had a roughish, granular appearance, with whitish spots (cholesterine?), standing out on a very dark brown-red ground.

Next morning Mr. Littlewood and I saw the patient together. She had passed a rather restless night, moaning a good deal. Her facial expression was, I thought, unfavourable, but she was partially under the influence of opium. There had been no sickness. Pain in the belly was complained of, and there was more distension than I had before observed. The pulse was about 100, occasionally intermittent; temperature 98° F. To continue milk and soda-water.

March 20th.—Although her facial aspect is not encouraging, there is no increase of abdominal pain or distension. Pulse 112; temperature 98.4°. To be allowed half a pint of milk to-day, and the same quantity for the night.—21st: Appears generally better; is more observant and disposed to talk; has passed flatulencies during the night. Temperature 99°; pulse 120. To have fully a pint of milk during the next twenty-four hours; the opium pill (half a grain) only night and morning.—22nd: Seen by Mr. Littlewood. Not so well. The abdominal wound is gaping and sloughy at the lower end, and the line of incision throughout is dull red; there is considerable fetid discharge, dark and grumous. Temperature 99.4°; pulse 112, weak. Aspect unfavourable.—23rd: Worse; has passed a restless night. The bowels were open for the first time last evening at 7, when a consistent motion was passed, but during the night has had several relaxed stools. She has a dull, apathetic look, dorsal decubitus, and sinks down in the bed. Temperature 100.4°; pulse 130, and running. The wound is offensive, but nearly dry.—24th: Died at 3 A.M. No post-mortem allowed.

*Remarks.*—The precise cause in cases of intestinal obstruction is often doubtful and not unfrequently, during life, indeterminate. It was so in the present instance; the nearest approach to a diagnosis that I could arrive at was that the obstruction was purely mechanical, as distinguished from mechanical and vital. I concluded this chiefly from the fact, already stated, that whilst the local conditions were not active and gravescent, the constitutional state became progressively more and more serious and urgent. With a clinical history such as we had here there was no reason to suspect the presence of a gall-stone or intestinal concretion, and I take it to be an unusual feature that a concretion of such size should have travelled the small intestines to within six or eight inches of the cæcum without having given rise to symptoms more or less prominent; beyond, however, occasional attacks of "biliousness," to which the patient had

been subject for years, there was no history of liver or bowel troubles. With regard to the composition of the concretion itself, it is largely composed of cholesterine mixed with various organic substances, the scales of the former being well shown under the microscope with the aid of polarised light. The fatal issue, in my opinion, was, mainly, if not entirely, due to the sloughing of the abdominal wound and to the condition of blood-poisoning consequent thereon. The unusually fat abdominal wall was remarked upon as an untoward element in the future of the case at the time of operation, and doubtless upon the low vitality of this fat tissue was the sloughing of the wound dependent. At no time did the intra-abdominal local (inflammatory) conditions occasion serious apprehension; but even after the operation and consequent relief to the intestinal obstruction the patient made no corresponding improvement in her general condition, whilst after a brief and partial rally she sank into a state of adynamia and exhaustion to which she finally succumbed.

## RELIEF THROUGH SPONTANEOUS BLEEDING IN PNEUMONIA.

By JOHN MEREDITH, M.D. EDIN.

THE following case of illness, if it were not for one or two circumstances associated with it, would not, I expect, possess any points of interest deserving of special notice. In consequence of these circumstances, the nature of which I shall presently describe, I began making notes from the commencement of my attendance. The story of it is briefly as follows:—On October 23th, 1881, I was requested to see a Mrs. M—, aged twenty-four, wife of a pensioner, residing a little way out of Wellington. I saw her about four o'clock in the afternoon, and found her suffering from an attack of pneumonia, complaining of a severe pain in the left side; skin dry; very frequent short respirations; quick pulse, and temperature 106°, fully. I found the pneumonic space was at the base of the left lung. The patient informed me that she experienced "a shivering fit" two days previous, and that she had been getting worse and worse ever since, and, further, that she was a little over three months gone in the family way. I directed that warm poultices should be applied at once to the pneumonic side, and that she should take a mixture composed of tincture of aconite and solution of acetate of ammonia in small doses at short intervals. At ten o'clock the same evening a message came, saying that Mrs. M— had some bleeding from the nose. I did not then attach much importance to this. At the same time I sent a few doses of ergot extract with hamamelis tincture for the patient to take if it persisted, and added instructions for applying cold cloths to the face and nape of the neck. At three o'clock in the morning of the 29th inst.—i.e., about five hours afterwards—an urgent message came for me to go and see her, and off accordingly I went. I found the patient now in a particularly exhausted condition, appearing all but bloodless; pulse hardly perceptible at the wrist, the breathing laboured and rapid, and there was very little power to speak, and that only in a feeble whisper. The skin was still dry, but comparatively cool; temperature 101°. Her bedclothes were saturated with blood, and there was much also in a basin beside the bed. The blood had escaped in spurts from the nose, and to some extent from the mouth; no cough with it, nor any effort at vomiting. It issued most likely from the Schneiderian membrane, and from it some escaped through the mouth. There was no pain anywhere complained of. The means resorted to, to arrest the hæmorrhage, for it was still going on when I reached the bedside, were injection of hazeline and water into the nostrils, continuation of the medicine sent at ten o'clock, dashing water on the face, or cloths wet with water, and holding up the arms of the patient. Before long the discharge became less and appeared to cease altogether in about an hour's time, and I felt at liberty to go away again. I called next at nine o'clock, and learnt that there had been a little bleeding since my early visit. At half-past twelve, when I saw the patient for the third time that day, some signs of improvement were perceptible. The hæmorrhage had ceased; the temperature was now 100.3°, pulse at the wrist a mere thread; no complaint of pain, but there was some cough, for which an ordi-

nary cough mixture with antimonial wine and chlorate of potash was ordered. She was able to partake of liquid food, which was freely supplied to her. After this there was nothing special to note for a few days, except that the area of dulness was extending in the left lung.

On November 3rd the temperature was 99°; pulse 110. The temperature had been about 100–101° since the morning of October 29th. The patient seemed to me at this stage to have passed the most dangerous point in her illness, and was able to speak, consequently I began making all the inquiries I could regarding this, to me, unprecedented form of systemic relief. Since then I have often thought of the case, and chiefly in connexion with what we term now the old practice of bloodletting in acute diseases. The remarkable change which followed the hæmorrhage from the nose on the night of the 28th was, as I have said, unprecedented as far as my experience is concerned. The body temperature fell about 5° in a very short time, and there was complete relief from pain.

I should mention, with regard to this patient, that she is one of those who never perspire—"at all events nothing to speak of," to use her own words, even in summer weather. The relief occurring in the way it did seemed to me but a pronounced illustration of the physical law, which is to the effect that a body expelling some of its component matter loses heat thereby and becomes cold, and that, no doubt, in proportion to the rapidity of the expulsion and the quantity of the loss. In this case there must have been a condition of extreme tension of the bloodvessels, and the portion of the contents which performed the part of expelling the other portions lost heat thereby and became cooled, but the expelling power pervaded the whole system; that being so, general cooling of the whole system followed. I do not know how the practice of systematic bloodletting arose in medicine, and if I did this would not be the place to attempt any historic account of it. There can, however, be no doubt, on the principle of there being nothing new under the sun, that cases like the one I am describing happen in all countries, and fall under the observations of medical practitioners; consequently it occurs to me, thinking over the question of general bloodletting with the light shed upon it by this case, that our predecessors, noticing the relief following spontaneous bleeding—but noticing also the exhaustion produced by excess, as in this instance—argued that, if moderate bleeding were resorted to, and that at a spot where it could be controlled, the evil effects of spontaneous bleeding would be avoided and the good only secured. At the beginning a few selected cases ending favourably would be a sufficient inducement for the adoption of the practice generally without reference to special selection. Thus it may fairly be presumed that a practice, originating from a good and judicious act, subsequently degenerated into a scandal and an injury to mankind, falling into such a depth of degradation as richly to deserve the scathing satires of Le Sage, as exhibited in his character of Dr. Sangrado, besides that of many other observers; from the consideration of which it may of a truth be asserted that degeneration is ever more fertile than evolution in the formation of varieties.

The spontaneous bleeding was the first point of interest in the case to which I wish to draw attention, and I would observe that it occurred on the third day of the illness. Usually in this district relief in such cases comes later, about the fifth day, and in the form of diaphoresis. As an example of this, I shall refer to another case of inflammation of the lungs which I had to attend about the same time, that of a Mrs. T—, aged about twenty-six years, suffering from over-lactation. On the evening of December 1st the temperature of her body was over 105°, with the usual symptoms of acute pneumonia. On the morning of the 2nd, being the fifth day of the illness, epistaxis began, and she saturated three pocket-handkerchiefs very soon, then diarrhoea with copious watery stools followed. The breasts, which had been distended, discharged about a quart of milk, according to her attendant's account. Her skin had not been particularly dry, but there was not much perspiration. The temperature fell very soon to 100°. Next day it was at normal. In this case the heated vascular tension found relief through more than one outlet, and in consequence there was no special prostration.

But to return to Mrs. M—'s case and show how it fared with the implicated lung and the uterine contents. In the course of a few days the pulmonary dulness indicating hepatization extended over the whole of the left side with

blowing-sound respiration and no crepitus audible. I was not able to detect any until about a fortnight after the commencement of the illness, when resorption was taking place. The laboured character of the breathing lasted for several days after the epistaxis crisis, and then became normal. The next point of interest was the effect of the illness upon the uterus and what it contained. On November 5th the patient complained of some discomfort rather than pain in the lower part of the abdomen, and there was tenderness on pressure, leading one to infer that there would be miscarriage before long. The pulse continued quick, always over 100, at times as high as 120. The temperature remained between 99.4° and 101°. It never went down to normal. These conditions left no doubt on my mind that the foetus in utero was dead. Still the pain and tenderness about the womb were at times very little complained of, but more so at others, and opiates were given for their relief. In spite of all, the patient was visibly improving, taking food fairly well and feeling tolerably cheerful. On November 29th some liquor amnii escaped, and it smelt offensively the attendant told me. I examined per vaginam and found the os uteri dilated to about the size of a fourpenny piece filled by a clot or something feeling like it. Next day regular uterine pains set in and the contents of the womb were expelled about three o'clock in the afternoon. The expelled substance consisted of twin boys, about the fourth month of uterine existence, attached to one placenta. All had a macerated appearance, but did not smell badly, not so bad, by all accounts, as the water which had escaped the day before. The foetuses had been dead for a long time, it was evident, I believe from the time of the epistaxis, thirty-three days before. These dead bodies had remained in the uterus all that time, and caused not one alarming symptom or anything calling for interference, bearing out an observation I often heard Mr. Lister make more than twenty years ago—namely, that living tissue possesses antiseptic power capable of delaying putrefaction for a long time. At the same time, there is no doubt, these bodies and their appendages kept up a certain amount of blood poisoning as indicated by the pulse and increased temperature. The patient suffered for a while from metritis, but in a few weeks this passed away and the lung affected completely recovered, but it was some months before she regained her usual state of health.

The histories of these two cases of acute pneumonia possess still another feature of interest, in that they both tend to confirm the view that the disease is of zymotic nature, belonging to the preventable order. For example, Mrs. M—'s house, although internally in good sanitary condition, was situated in close proximity to a bad-smelling privy, the smell from which pervaded her house both before the accession of the illness and at the commencement of it.

Mrs. T—, like many country labouring people, had potatoes stored in her bedroom, and the decay smell from these struck one at once on entering the room. The sanitary condition of her house in other respects was fairly good, both inside and out.

Wellington, Somerset.

## STATISTICS OF TETANUS IN THE MEDICAL COLLEGE HOSPITAL, CALCUTTA.<sup>1</sup>

By JAMES R. WALLACE, L.R.C.S., L.R.C.P. EDIN.,  
HOUSE-SURGEON, MEDICAL COLLEGE HOSPITAL, CALCUTTA.

THE frequency of tetanus in Bengal, as evidenced by the records of the Medical College Hospital—which represent fairly a very large section of the prevailing diseases which come under observation throughout this Presidency,—and its participation in augmenting the mortality in surgical operations, as further demonstrated by reference to the practice of surgeons connected with this largest of Indian hospitals, make a brief summary of their experiences worthy of our notice, not only as being interesting, but instructive. The notes on tetanus in the Medical College Hospital, which I am about to record, consist of an analysis of a tabulated statement of cases kindly placed at my disposal by Dr. McLeod and some jottings from other medical and surgical records of this hospital. During the ten years from

<sup>1</sup> Read before the Calcutta Medical Society.

1869 to 1879 there were 280 cases of tetanus admitted into the Medical College Hospital, in all of which the well-marked symptoms of the disease were more or less fully developed at the time of their admission into the wards. Of these 212 died. Irrespective of these 280 cases, 23 others occurred in the surgical wards, following operative interference of various kinds, and all of these terminated fatally. Of the former series of cases, 159 were of the idiopathic variety, the subjects being 93 males and 66 females, of whom 53 of the former and 58 of the latter died. Of the traumatic form there were 121 cases, 67 males with 64 deaths, and 54 females with 37 deaths.

With regard to age and race: in infants up to fourteen days old there were 34 cases, of which 13 were natives and 21 Europeans, with 29 deaths in all. From one to five years, 5 cases, 4 natives and 1 European, with 3 deaths; from five to fifteen years, 23 cases, 20 natives and 3 Europeans, with 11 deaths; from fifteen to forty-five years, 195 cases, 175 natives and 20 Europeans, with 154 deaths; from forty-five years and upwards, 23 cases, 21 natives and 2 Europeans, with 15 deaths.

With regard to season: during the winter months—namely, November, December, January, and February, this series shows 96 cases admitted, 38 from traumatic and 58 from idiopathic tetanus, with 80 deaths. The early summer months—March, April, and May—give a total of 71 cases admitted, 28 traumatic and 43 idiopathic, with 44 deaths. The months of the monsoon, or rainy season—namely, June to October inclusive—show 113 cases, 53 traumatic and 60 idiopathic, with 88 deaths. The minimum of admissions was in July and the maximum in December.

With regard to the etiology of this series of 280 cases, I have been able to trace the history of 117 of the idiopathic, and in 94 of the traumatic to note the nature of the injuries giving rise to the disease. The various causes, with the number of casualties from each, are as follows:

1. Exposure to cold and wet	47
2. Menstruation, pregnancy, and abortion	29
3. In infants under fourteen days old	23
4. In persons suffering from fever, dysentery, general debility, and privation, in whom there is no distinct history of exposure	24
5. Injuries	94

#### Nature of Injury.

(a) Wounds of all varieties	35
(b) Machine injuries	23
(c) Contusions	13
(d) Burns and scalds	6
(e) Compound fractures	17

The duration of the disease will be ascertained from the following record of 212 fatal cases:—

	Cases fatal.
Within two days	88
From two to five days	41
From five to ten days	26
From ten to twenty-two days	23
Above twenty-two days	34

With regard to treatment, the records give evidence of trial of every known remedy, but the plan notably in use in all the medical and obstetric wards has been by free purgation and the administration of such anodynes and antispasmodics as chloral, morphia, and atropia, given by the mouth and subcutaneously, opium in combination with ammonia, Indian hemp, belladonna, potassium bromide, and Calabar bean. Opium-smoking has been largely tried in the obstetric wards. Quinine and other preparations of cinchona found place in the chronic cases. In the surgical wards, the removal of irritant particles, stretching of nerves, and amputation have been resorted to for the relief of the traumatic form, in addition to the already named medicinal means.

**Results.**—There were 68 cures in 280 cases, or 14·16 per cent. Of these 53 were among the idiopathic and 15 among the traumatic. In subjects under fourteen days old, the recoveries were in the proportion of 1 to every 6 cases; from one to five years, 1 in every 2·5 cases; from five to fifteen years, 1 in every 2 cases; from fifteen to thirty-five years, 1 in every 5 cases; from thirty-five to forty-five years, 1 in every 6 cases; from forty-five years upwards, 1 in every 3·23 cases. After revising the notes in forty-six of the cases in which recovery took place, I do not find one in which

success can be attributed to any single remedy, or any individual plan of treatment, though in most of them chloral and cannabis indica were more largely used than other drugs. The practice in which surgical operations were performed for the relief of the sufferer has been attended with most unfavourable results. In two cases the sciatic nerve was stretched for tetanus arising from wounds of the foot, in one instance the median was subjected to the same operation for disease originating in a comminuted fracture of the thumb, and in neither of these cases did abatement of the spasms or other improvement in the patient's condition attend the procedure. Amputation of the hand in two cases, of the forearm in three, and of the leg in two, was resorted to without effect.

The second series of 23 fatal cases comprises those arising after surgical operations in the wards during the years from 1869 to 1879. There were altogether during this period 2148 major operations performed in the Medical College Hospital, with 402 fatal results from all causes, among which 23, or 5·7 per cent., are attributable to tetanus, and occurred in the following instances:—

	Cases.
Excision of scrotal tumours	8
Amputation of foot and leg	7
Amputation of hand and arm	6
Excision of simple tumours	2

These statistics serve to illustrate certain facts in connexion with the general characteristics of tetanus in Bengal: how it affects the varied population, how the disorder is altered in its virulence, and the frequency of its occurrence with special reference to age, sex, and season, how it influences the results of surgery, and in what direction the efforts towards alleviation have tended. Thus we find that trismus nascentium occurs more frequently among the children of Europeans than among those of natives, for out of 34 cases 21 were Europeans, and this observation is all the more striking when we consider the comparatively small proportion the European element is among the vast native population of Bengal. Referring still to infantile tetanus, we find that it is indefinitely written about as being of the idiopathic variety; if, however, it is held that the source of irritation lies in any abnormal changes in the ligatured and divided umbilicus, then it is truly traumatic. In Mahomedan and Jewish infants in this country, however, there is no doubt in many instances as to the disease being traumatic, even though the umbilicus be free from complication. With these religious persuasions the custom is to circumcise an infant on the eighth day, and in many instances tetanic symptoms supervene upon this procedure. Thus I find in nine of the infants affected the penis was the focus of irritation to the nervous system, and in two cases the application of anodyne poultices to this part resulted in allaying the acuteness of the symptoms and in finally curing the little patients.

In adults tetanus seems equally dispersed among Europeans and natives; males were more affected than females, and in infants and adults the disease was more frequent than in children and persons over forty-five years. In women idiopathic tetanus is very frequently associated with the puerperal period and with menstruation, for in 52 females affected, 29 were either menstruating or they had just been confined at full term, or they had aborted. The majority of cases occur in the winter months, and though no season enjoys a perfect immunity, least of the cases are noted in midsummer, the maximum being in December, and the minimum in July.

The general death-rate in tetanus, as shown by the statistics of the years from 1869 to 1879, is 75·7 per cent.; in the idiopathic it was 69·7, and in the traumatic so high as 83·4 per cent. The disease is certainly most fatal in the early stage, almost one-third of the cases dying within the first two days of the attack, whereas recovery may almost as surely be prognosticated after the disease has passed the fifteenth day.

Of injuries resulting in tetanus, those by machinery, compound fractures, and punctured wounds have yielded the largest proportion of cases.

The appearance of tetanus in operation cases has been attended with the most deplorable results, as in 23 cases which occurred not one recovered. It appears that operations upon the scrotum, involving much interference with the testis or cord, are peculiarly prone to the supervention of tetanus. Thus in five out of eight cases, in which elephantoid

growths were removed from the scrotal region, castration seemed necessary and was accomplished, and in all these tetanic symptoms were manifested. Another case in point was in the radical cure of hernia by Wood's operation; here the patient died of tetanus, and it was found on post-mortem examination that the spermatic cord was strangulated in the wire suture used in approximating the pillars of the abdominal ring and obliterating the canal.

Our treatment, though aiming principally at removal of the cause and the subsequent tranquillising of the nervous system, seems to border much on the domain of empiricism; for when one analyses the treatment one is compelled to confess ignorance as to the part which any single remedy may have exerted upon a fortunate occurrence, and to say that the cure seemed accidental. However this may be, the success in the treatment of tetanus in the Medical College Hospital during the years from 1869 to 1879 is even more favourable than books on the subject would lead us to surmise; and if any drugs are to be relied on favour is decidedly on the side of chloral, opium in the form of morphia, and opium-smoking. Unfortunately, nerve-stretching has not been attended with the same success in tetanus as in the case published by M. Paul Vogt, nor even with the partial relief reported as occurring in two cases which came under the treatment of Dr. Ebenezer Watson of Glasgow. Amputation has not afforded any satisfactory results, nor has division of nerve-trunks been attempted as a *dernier ressort*.

## ON THE INCREASE OF CARBONIC ACID IN THE ATMOSPHERE.

AN ATTEMPT TO DETERMINE THE PERIOD WHEN THE AIR WILL BE IRRESPIRABLE.

By T. HATFIELD WALKER, L.R.C.P., F.C.S., F.M.S.,  
MEDICAL OFFICER OF HEALTH, LONGTOWN.

THE question of how long our coal-fields will last has been frequently discussed, and astronomers have endeavoured to determine the life of the sun, but the important question of how long the atmosphere will continue to be respirable has not, I believe, ever been considered. We are taught that plants, by absorbing the carbonic acid formed in breathing and combustion, &c., prevent the atmosphere becoming overcharged with this gas. Doubtless, in bygone ages, when the earth was almost covered with trees, and combustion was confined to the burning of wood, this was correct, but little consideration is required to show that this is now no longer true. We have every evidence that in primeval ages the atmosphere abounded in carbonic acid; this abundance of carbonic acid, together with the high temperature, caused very luxuriant vegetation, which rapidly fixed the carbon of the carbonic acid, giving out the oxygen. As ages rolled on this carbon, abstracted from the atmosphere, was gradually stored up in the bowels of the earth as coal, and thus the excess of carbonic acid in the atmosphere became decreased until the latter became capable of supporting the lower forms of animal life. With the development of the higher forms of life commenced the accumulation again of carbonic acid in the air, but until the birth of man this would have very little effect. With the birth of man a very great influence is brought to bear. Man is the only animal capable of making a fire; but even his influence, so long as he continued to burn only wood, would not be very great in poisoning the air, but when he commenced to give back to the atmosphere the millions of tons of carbonic acid slowly abstracted from the air, and stored up through countless ages, he rapidly tends to bring back the atmosphere to its original condition. It appeared to me that it would be very interesting to endeavour to make some guess as to the influence on the atmosphere of the enormous quantities of carbonic acid which are thus yearly added to it. Not only is this a question very interesting from a speculative point of view, but if the consumption of coal continues to increase as it has done during the last twenty years, it will soon become a question of practical importance.

To make the subject as clear as possible I will first consider the sources of carbonic acid, and balance against them the influences which tend to decrease the amount in the air.

The sources of carbonic acid are—(1) Animal respiration; (2) decay of wood plants, &c.; (3) manufactures, as burning of limestone, fermentation, &c.; (4) craters of volcanoes and caverns; (5) combustion. The first of these—viz, respiration, can have little permanent influence, for the animal only gives back to the atmosphere what has previously been absorbed by the plants on which the animal feeds. Decay also only gives back what has been previously abstracted. In the burning of limestone, also, we only return what the animals, from the shells of which the limestone is built up, have previously absorbed. The amount given out by volcanoes, &c., is too small to require notice. We have therefore only left to consider the carbonic acid evolved by combustion. The influences which tend to decrease the carbonic acid are—(1) Absorption by vegetation; (2) solution in water from which it is absorbed by shell animals in building up their shells, but we have balanced this in the burning of limestone, so we have only the influence of vegetation to consider. All cereals, grass as food, can have no permanent influence, as the carbonic acid is given back to the atmosphere by respiration. All animals also give back in their decay what they have previously stored up. The same applies to shrubs and trees, for more wood is being destroyed by burning and decay than is being formed by growth, so we see that vegetation, instead of storing up carbonic acid, is now actually increasing the amount in the atmosphere, and thus the whole of the carbonic acid given off by the combustion of coal and coal products, as petroleum, &c., is permanently added to the atmosphere.

In answer to a question Sir Henry Bessemer very courteously informs me that the amount of coal annually consumed throughout the world cannot be short of 400 million tons; this gives 336 million tons of carbon, which equals 1232 million tons of carbonic acid annually to the atmosphere, and thus a billion tons will be added in from 700 to 800 years, which will increase the amount of carbonic acid in the air from three billions, which it at present contains (the total weight of the atmosphere being 5210 billion tons) to four billions. But as the amount of coal annually consumed is rapidly increasing, probably in a single century a difference will be made which cannot fail to have a great influence on vegetation, and probably on the health of man; and there can be no doubt the air will be quite irrespirable long before the total known coal contained in the world is consumed. Professor Rogers estimates the amount of coal in America and Europe, in round figures, at ten billion tons; adding to this that of China and the rest of the world we get between twenty billion and thirty billion tons, which is equal to between sixty billion tons and ninety billion tons of carbonic acid. Even the lesser of these figures gives an increase of carbonic acid in the air equal to twenty times the amount it at present contains—i.e., it will increase it from '04, as at present, to '8 per cent. Dr. Angus Smith found that feebleness of the circulation was induced by breathing an atmosphere containing 0.15 per cent. when only breathed for a short time, and a much lesser quantity than this lessens the elimination of the carbonic acid from the blood, and thus produces headache, and from its retarding nutrition induces debility and other diseases. Taking these figures as correct, we see that the air will be incapable of supporting life, even when only one-sixth part of the coal known at present is consumed, and as the amount of coal is probably double this, there can be little doubt that the air will be irrespirable before one-tenth part of the available coal is consumed.

Carlisle.

## ON A CASE OF SARCOMA; PETECHIAL ERUPTION; DEATH.

By L. W. MARSHALL, M.D. ABERD.,  
SURGEON TO THE CHILDREN'S HOSPITAL, NOTTINGHAM.

I AM led to publish the following case in consequence of its peculiar termination, and because I am told by my friend Dr. Goodhart that one or two similar cases have been observed at Guy's, the cause of the rash being, as yet, not very clear.

Ada R—, aged twelve years and nine months, was admitted under my care April 13th of this year. She then complained of pain in her right thigh and back and was believed to be suffering from hip disease. On examination

I came to the conclusion that she had a collection of matter (chronic abscess) in her psoas muscle of that side. Her limb was semi-flexed and there was distinct fulness over the right sacro-iliac joint. When standing her limb was advanced and she rested on her toes. Pain was most marked, yet not severe, at the top of the thigh on the inner side. The history of the case dated from the previous summer, but she relinquished her work as recently as three weeks prior to admission. A normal temperature was recorded. The treatment was confined to absolute rest and cod-liver oil.

On April 20th in the afternoon, being in the hospital, I was called hastily to her and found her lying with the surface cold, face pallid, pulse small, clonic contraction of the muscles, first on the left, then on the right side, the hands and arms only being affected. Her legs were drawn upwards towards her abdomen, no facial distortion; she moaned, but appeared to be conscious, although she did not answer questions put to her. Urine was passed freely during the attack. Bowels not having acted for a few days an enema was ordered, which returned. Ten-grain doses of bromide of potassium were given every third hour.

Nov. 22nd: No urine had been passed and a catheter was therefore used. Eyeballs twitching. A raised rash was formed not very unlike a scarlet fever eruption, but more dusky and mottled. Its distribution on the chest was in the line of the intercostal nerves, the ribs being mapped out, and a distinctly intervening surface free from rash was noticeable at mid-sternum. This appearance was most striking on raising the patient's dress. On the abdomen the rash had extended to the umbilicus, the same middle division, but did not appear on the front of the lower part of the abdomen, excepting in the line of the ilio-inguinal nerve on either side. There was also a similar patch on the inside of the left thigh. Pupils very large, but still acting feebly to light. Left leg rigid. At 8 P.M. the head was thrown back; both legs were moved. Temperature 102.4°. Quite unconscious.

April 23rd: Pupils dilated and fixed; left believed to act very slightly. Rash now occupies the same lines of distribution previously described, but is distinctly petechial. Trunk inclined towards the left side; left angle of mouth depressed; eyes partially closed (left eye injected, and covered with a film). Catheter was again used. In the evening of this day she died.—24th: Post-mortem revealed a large growth springing from the transverse process of the last three lumbar vertebrae, burying itself in the substance of the right psoas muscle, which was tense and expanded, anteriorly, over it. The right ureter was displaced towards the middle line and rendered "varicose." The genito-crural nerve was flattened out, and the external cutaneous and anterior crural also. Kidney on that side was unaffected; mesenteric glands enlarged; both lungs adherent over greater surface to the chest wall; no effusion; no deposits in the lung or any other organ. Brain was examined, and nothing unusual was found.

I append to this a microscopical examination which Mr. Handford, of the General Hospital, has kindly made for me: "A microscopic examination of the tumour showed it to be one of the mixed sarcomata. Portions of every section consisted of masses of large, irregularly rounded cells, about the size of a white blood-corpuscle, and containing one or more nuclei. The remaining portions presented more the appearance of a 'small-celled infiltration,' there being innumerable small round cells, about one-third the size of a red corpuscle, with a few spindle cells, in a fibrillated intercellular substance. There were no signs of degeneration, but everywhere pointed rather to active growth and proliferation." The case was seen by Dr. Seaton with me.

ROYAL COLLEGE OF PHYSICIANS.—The following gentlemen were elected examiners on the 27th ult.:—Chemistry and Chemical Physics: Drs. Thomas Stevenson, W. J. Russell, C. R. A. Wright, and Mr. C. W. Heaton. Materia Medica, Medical Botany, and Pharmacy: Drs. W. H. Stone, Moxon, Buchanan Baxter, and F. T. Roberts. Osteology, Anatomy, and Physiology: Drs. Pye-Smith, Allchin, Curnow, and Mr. William Anderson. Medical Anatomy and Principles and Practice of Medicine: Drs. Fincham, Pollock, Southey, and Sydney Ringer. Midwifery and Diseases peculiar to Women: Drs. Playfair, Galabin, John Williams, and Potter. Surgical Anatomy and Principles and Practice of Surgery: Messrs. Pollock, Sydney Jones, John Couper, and Alfred Willett.

#### GUYS HOSPITAL.

CASES TREATED BY HYPODERMIC INJECTION OF PILOCARPINE; REMARKS.

(Under the care of Mr. HIGGENS.)

FOR the following notes we are indebted to Mr. Trapp, dresser in the eye department:—

CASE 1. *Detachment of Retina, with Floating Opacities in Vitreous in both Eyes.*—Catherine H—, aged thirty-nine, was first seen amongst the out-patients March 21st, 1882, and at once admitted. About nine months before, when reading, sight of right eye was suddenly reduced to perception of large objects. Vision remained about the same up to date of admission. Four months after the beginning of the trouble in the right she first noticed a fog before left eye, the sight of which got gradually worse.

On admission the right eye had perception of shadows only. The left could scarcely count fingers. The ophthalmoscope showed a very large detachment of the retina in the right eye, a detachment of the lower and outer part of the retina in the left eye, and floating opacities in the vitreous in both eyes.

March 27th:—Hypodermic injection of one-sixth of a grain of nitrate of pilocarpine. In about four minutes profuse sweating and ptialism set in, which lasted for over an hour. The injection was continued night and morning, the patient being kept in bed. At times she complained of a good deal of thirst and itching in skin of trunk and arms.

April 3rd:—Left eye counts fingers, and can tell one from the other; reads Jaeger No. 20 at two feet doubtfully.—5th: Quantity of pilocarpine increased to one-third of a grain.—6th: Was sick after injection yesterday evening, and has had headache ever since. Pilocarpine increased to half a grain.—9th: Very sick after injection yesterday; its effects lasted nearly two hours.—11th: No further improvement had taken place; the injections were discontinued.—17th: The retinal detachment appeared to be about the same, but the opacity in the vitreous was thought to be rather less. The patient was seen some weeks later, and was then as bad as at time of admission.

CASE 2. *Detachment of Retina in Left Eye; Cataract; no perception of light in Right Eye.*—Elizabeth S—, aged forty-four, admitted April 17th, 1882. She had had two still-born children, three children born alive, all of whom died under two years of age, and two miscarriages; had suffered from ulcerated throat. About eleven years ago—immediately after the last miscarriage—the patient suffered from dropsy. At this time noticed vision becoming dim; had no pain or inflammation in the eyes; the sight failed gradually, and sixteen months before admission the right eye had become quite blind. She attended the out-patient department in February, 1882, the sight of the left eye having grown gradually worse in the last few months; the right eye was quite blind, and the lens opaque; in the left eye there was good perception of shadows; the retina was displaced at its lower part.—April 20th: Hypodermic injection of one-sixth of a grain of nitrate of pilocarpine. Profuse sweating followed shortly after, and lasted some time.—22nd: Sweating lasted two hours; complains of being faint and thirsty; says she can see better.—24th: Can see the colour of the bed-cover, also figures moving about the ward.—25th: Left eye counts fingers. Pilocarpine increased to one-third of a grain.—28th: Sight about the same. Pilocarpine increased to half a grain. The injection was discontinued on the 29th, having been given morning and evening since the 20th. The patient had been in bed the whole time.

On July 3rd condition the same as on admission.

CASE 3. *Opacity in Vitreous of both Eyes, probably Blood.*—Archibald C—, aged seventeen, admitted April

21st, 1882. Three years before some dust was thrown into the left eye; a slight attack of inflammation followed, for which he was treated at the Royal London Ophthalmic Hospital. He did not notice any failure of vision of the left eye till on one occasion the right eye was covered, when it was found that the left had only perception of shadows. The eye entirely recovered, and two years before admission into Guy's his sight was as perfect as ever. About a year before admission he began to notice floating opacities in both eyes; in sunlight the opacities appeared red. (Patient now remembers that about five years ago he suffered in a similar manner, but quite recovered.) The floating opacity in the left eye soon became fixed and obscured vision so much that only perception of shadows remained. The patient attended amongst the out-patients in November, 1881. At that time vision was the same as on admission—i.e., right eye reads Jaeger No. 1 at one foot and 6-6ths, when opacities had floated out of the way. Left eye had perception of shadows only. The ophthalmoscopic appearances were: right eye, dark floating opacities in vitreous, settling into a dark mass at the lower part of fundus; left eye, yellowish reflection from whole of fundus; retina appeared to be detached. The patient's general health was good. He did not suffer from constipation.—22nd: Hypodermic injection of one-sixth of a grain of nitrate of pilocarpine; injection followed by profuse sweating.—25th: The quantity of pilocarpine increased to a quarter of a grain; on the 28th to half a grain; on the 29th the patient complained of headache. As there was no alteration in the condition of the eyes, the injection was discontinued. He was kept in bed during the time that he was treated by the injection.

July 18th:—The patient is still under treatment. For the last month he has been rubbing mercurial ointment into the temple. The right eye varies from time to time as fresh hæmorrhages occur; but when there has been no bleeding for about a fortnight, vision is as good as on admission. The left eye remains quite blind.

*Remarks.*—It appears from these three cases that if pilocarpine does any good it does it within a week, and that it is useless to continue the injections longer. Its effects do not last. Cases 1 and 2 were decidedly improved, but soon relapsed. The patients objected so much to the treatment that they were not pressed to try it again; possibly the same amount of improvement would have taken place had the injections been repeated after some weeks' discontinuance. Case 3 is a good instance of a class of cases which unfortunately are not very uncommon—i.e., repeated bleedings into the vitreous humour occurring in young adult males, against which treatment seems almost powerless, and which end sooner or later in total blindness.

### THE QUEEN'S HOSPITAL, BIRMINGHAM.

SUBPERIOSTEAL RESECTION OF HIP-JOINT FOR CHRONIC HIP DISEASE; FRACTURE OF FEMUR DURING OPERATION; CURE; REMARKS.

(Under the care of Mr. WEST.)

JAMES P—, aged thirteen, was admitted into the Queen's Hospital on Oct. 2nd, 1881, in a feeble anæmic state, suffering from advanced hip disease on the left side. The limb was shortened two inches, adducted, and the knee flexed, very painful when moved; there was evident muscular atrophy. A sinus existed over the great trochanter leading to carious bone, and an abscess was forming over the anterior superior iliac spine. The disease began six months previously (as he states), from carrying heavy baskets of goods for a grocer. He had previously been in hospital for three months, and relieved by rest and extension. The same treatment was employed, good diet, cod-liver oil, and syrup of iodide of iron being also given. No improvement, however, resulted, but the hectic symptoms and exhaustion rather increased. Mr. West on Dec. 3rd resected the joint by a single straight incision, preserving as much as possible the periosteum. In turning the head of the femur through the skin wound considerable force was required to break down the adhesions which had formed between the femur and the dorsum ilii, close to the acetabulum, and while an assistant was using the lower end of the femur as a lever, with a view of turning the head out of its new socket, the femur was broken about the middle. This accident at the time rendered the excision of the head of the femur rather

difficult; but, strange to say, it did not militate against the ultimate success of the case. The operation was performed antiseptically minus the spray, and the limb was put up with an extension apparatus after an interrupted splint had been applied along its outer side.

On Jan. 4th, 1882, the antiseptic dressing was discontinued and the wound dressed with sulphate of copper lotion.

On Feb. 2nd, a starched case was applied to the limb. The fracture seemed to have united, and the line of incision was healed except at one or two points.

On March 6th a Thomas's splint was applied, and the patient was sent to the Convalescent Home for Children at Solihull, where he remained till the beginning of June, steadily improving in health and gaining increased power in the thigh. The limb is now only an inch shorter than the sound limb, although it was two inches less before the operation. There is much deposit of new bone, and the site of the fracture can now scarcely be made out.

*Remarks.*—Professor Sayre, in his excellent practical work on Orthopædic Surgery (p. 290), alludes to the occurrence of fracture of the femur in the operation of resection of the hip, if care and gentleness are not employed in using the femur as a lever. This case is a further proof of the necessity for such care in dealing with bone that is weakened by disease, but it also teaches us that when fracture does unfortunately occur, the result, both as to length and strength of the limb, may be all that could be desired. It confirms the views enunciated in THE LANCET annotation of July 1st, 1882, on "Lengthening of the Femur after Division," *a propos* of the specimen shown by Dr. Moore at the recent meeting of the American Medical Association, in which "an interval between the fragments of more than an inch in length was completely filled with new bone."

### BOOTLE BOROUGH HOSPITAL.

SEVERE INJURY TO RIGHT FOOT; NECROSIS OF METATARSAL BONES; OPERATION; CURE; REMARKS.

(Under the care of Dr. C. SWABY-SMITH.)

FOR the following notes we are indebted to Mr. Chas. A. McLean, M.B., house-surgeon.

J. H—, aged forty-three, seaman, was admitted on Dec. 29th, 1881, suffering from an injury to his right foot, which he sustained while engaged in one of the Cunard boats, repairing the sails on one of the masts, from which he fell. He was attended by the ship's doctor previous to admission.

On examination there was found what appeared to be fracture of the metatarsal bones. Sinuses had formed on the inner and outer aspects of the foot, which altogether presented disorganisation of its constituent joints and bones. Dr. Swaby-Smith made a careful exploration of the parts, and found necrosed bone, more especially in the metatarsal aspect of the great toe. He left the parts alone for two days, when, on re-examination, the probe revealed disintegrated bony structure, which ended in the formation of pus, and its consequent extravasation along the muscles and synovial structures. The patient was anaesthetised (chloroform having been administered), and Dr. Smith made an incision over the metatarsal joint of the great toe, and removed about half of this bone. The subsequent local treatment consisted in the application of carbolic oiled (1 in 10) lint to the part, with pressure on the plantar aspect of the foot, and careful attention to cleanliness, the foot having been bandaged from the toes upwards. The outer aspect of the foot, which presented a sinus, and from which fragments of necrosed bone which had gradually worked their way to the surface had been removed, steadily showed signs of repair. Sinuses had also formed between the great and second toes, and between the fourth and fifth. From these pus came at first in considerable quantity, originating from the plantar aspect of the foot; for when pressure was applied here the matter was obviously finding an exit in the regions already mentioned, and also over the sinuses which existed in the metatarsal bones of the great and small toes on the dorsum of the foot. The dressings of carbolic oiled lint were, a fortnight subsequent to operative procedures, changed, nitric acid lotion (half a drachm in eight ounces of water) having been substituted. His diet on admission was ordinary; but he got milk and beef-tea diet on Jan. 24th, 1882.

The patient made rapid progress, the sinuses healing up, new bone having been thrown out; although now a little pus was to be seen working its way between the great and second toes, which with pressure on the plantar aspect of the foot with a pad of lint, daily dressing, and syringing with carbolic lotion (one in forty) and careful bandaging, was suppressed. When discharged and made an out-patient, on April 25th, 1882, the foot presented a healthy appearance, both sinuses having healed—i.e., those over the dorsum of the foot; and dry lint dressing was substituted for the lotion. His ankle-joint was not involved in any way during his treatment here, every movement of the same being effected with moderate fairness. Latterly a mixture containing iron and arsenic was ordered him.

*Remarks.*—This case illustrates the good results produced by time, in conjunction with pressure, careful attention to cleanliness, dressing, and the removal of all sources of irritation from the part. At first, on patient's admission, the foot presented such a disorganised appearance that it was doubtful whether it could be saved, amputation through the ankle-joint being the question then discussed. Fortunately enough for the poor fellow, whose occupation is a seaman, his foot has been saved; he is now able to walk on it, and presents himself here from time to time, proud of his once useless foot.

### GOCULDAS TEJPAL HOSPITAL, BOMBAY.

#### CASES OF ELEPHANTIASIS OF SCROTUM.

(Under the care of Surgeon-Major T. CODY.)

The following cases continue the report begun in the "Mirror" on July 29th, 1882.

**CASE 2. Elephantiasis of Scrotum and Penis; Removal by Operation; Tetanus; Death.**—A Mussulman priest, aged forty, was admitted with a large elephantoid tumour, enveloping both scrotum and penis. The patient was very stout and flabby, and had led a lazy, indolent life. He stated the tumour was of some eighteen years' growth, and that latterly he had been subject to periodic attacks of fever, accompanied by a tense painful feeling in the growth. He was detained in hospital for a week before the operation was performed. On being brought under chloroform it was found the penis was imbedded in the tumour, and could not be drawn forward. The index-finger of the left hand was passed down the opening till the glans was felt. A strong scalpel was passed along the finger, and an incision made upwards which exposed the glans. It was then seen that the prepuce was healthy, and it was carefully separated by a circular incision from the adjacent unhealthy surface. The penis was then seized; dissected out and reflected upwards. An incision was now carried downwards and outwards on the right side, and the fingers were used to search for and free the right cord and testicle. A large hydrocele was discovered in the right sac, which was evacuated by a free incision. The right testicle being found to be completely atrophied, it was excised and the cord secured. An incision was then carried from the commencement of the former and from the root of the penis, downwards and outwards on the left side to the extent of five or six inches. It was found that on this side and on the back of the tumour there was much more healthy integument than on the right side, and as much of it as possible was preserved to form a flap. There was a hydrocele also on the left side, but somewhat smaller than the right, which was evacuated, and then the testicle, which was found healthy, was reflected upon the abdomen. The incisions were now made to meet at the back of the tumour, and its substance was divided by a Catlin. There was very free hæmorrhage, which was controlled in the manner referred to in the former case, and fine vessels had to be ligatured. In addition, the surface of the wound oozed considerably—a circumstance attributed to the plethoric habit of the man. The testicle was next brought down, and fixed in the centre of the wound by passing through its outer covering three of the wire sutures used to bring the edges together, which came excellently into apposition. About half an inch at the lower end of the wound was left free to admit the ready exit of the discharges, but the remainder was closely brought together up to the root of the penis. The only covering left

on the penis was the healthy prepuce, and this was tied back by three sutures to the subcutaneous tissue, so as to act as a point from which granulations and a healing process might start. The whole surface was enveloped in carbolic dressing, and the man removed to bed. The dried mass of the tumour, after it had oozed away for some time, weighed exactly 13 lb., and it was calculated that the escaped fluid weighed as much more. For the first twenty-four hours there was some oozing, which stained the dressings, but this passed off, and everything progressed most favourably till the eleventh day after the operation, by which time all the sutures and ligatures had been removed, and the discharges, which were all through healthy, were very slight. At the morning visit on this day the patient complained of stiffness of the jaws. Full doses of chloral, with stimulants, were prescribed, but without the effect of staving off the spasms, which came on next day. Nothing could be noticed in the wound to account for this setting in of tetanus; and it may be remarked that all through its course till the patient's death the wound continued to heal day by day, so much so that at the end the penis, which had been completely denuded, was more than three-parts covered with new integument. All the known remedies were tried, but nothing was found to give so much relief or to stave off the spasm so effectually as large doses of chloral and brandy.

Thirteen days after he first complained of stiffness of the jaws, and twenty-four after the operation, he died in strong spasm, which seemed to arrest the respiration.

**CASE 3. Elephantiasis of Scrotum; Removal by Operation; Recovery.**—A Hindoo, native of Madras, aged thirty-seven, had been labouring under the disease for five years. The patient was a very thin, unhealthy, cachectic-looking man, and on admission was found to have a tumour enveloping the lower part of the scrotum only. It was very angry and inflamed, showing patches of sloughing on the surface, and was accompanied by hectic. Although the patient was in a very low state, operation was decided on, as it was thought that his low hectic condition could be best treated by the removal of what was too evidently its cause. The tumour, which weighed only three pounds and a half, was removed with the right testicle, which was found extensively diseased. There was sufficient flap left to cover the left testicle and to allow of the edges being brought into apposition over it. The healing in this instance was very slow, and a large abscess formed along the course of the right cord, after its ligature came away, and had to be laid open. This discharged freely for about a fortnight under poultices, and eventually closed up, after which the wound took on a more healthy action.

About seven weeks after the operation the wound had perfectly healed, and the man left the hospital much improved in every way.

## Reviews and Notices of Books.

*Manuel d'Hygiène Industrielle.* Par Dr. HENRI NAPIAS. Avec Figures. Paris: G. Masson, éditeur.—The formidable volume before us will become a useful book of reference not merely for French readers, but for all who can read French. The work is truly cosmopolitan in its character, and in this will be found at once its principal utility and originality. Dr. Napias divides his subject into three sections: First, General legislation affecting all industries, such as Factory Acts; secondly, the workshop and manufactory, and the classification of industries according to the risks involved to public health; thirdly, the materials employed, the great industrial poisons, lead, phosphorus, &c. In each of these sections we have put before us not merely the French law, but extracts showing any particular feature of the laws of the various European Powers. Thus in the first section we find that while the French law displays great solicitude on behalf of the proprietors of houses situated in the neighbourhood of unwholesome manufactures, nothing is said on behalf of the workmen employed in these trades. The Belgian law of the 29th January, 1863, seeks to mitigate all mischief affecting "either the workmen employed or the neighbours of the factory." In the Swiss law, which is given

in full, the condition of the workmen is taken into consideration in almost every schedule. The Prussian law gives the authorities both instructions and the power to protect the lives of workmen, and insists on the efficient ventilation of factories. In this analysis of the various laws of Europe, the English Factory Act holds a prominent and unique position as the only law that insists on the necessity of good drainage, and gives some details as to what measures should be adopted to secure this end. On the other hand, the French law is the most perfect in Europe in so far as the classification of unwholesome industries is concerned, and their division in three categories. In this respect the French law has served as a model to many other countries, and has been imitated notably by Portugal and Belgium, though Dr. Napias gives a list of industries classified in Belgium and not in France, and *vice versa*. Under the same section we have an analysis of all the laws regulating the work in factories of women and children in France, England, the various States of Germany, Austria, Denmark, Spain, Holland, Switzerland, &c. This compilation will be of the utmost use to the sanitary reformer, the legislator, and the medical officer. The experience thus gathered, spreading over many hundred pages, is too complex to render a summary possible within our limited space. But we may note, in passing, one important feature of the Austrian Sanitary Act of 1876, which commends itself to imitation by all nations. According to Article 82 of this enactment, all Austrian employers are compelled at once to report any case of contagious disease that may occur among their workpeople. Those who are aware how often the manufacture of clothes is the means of spreading disease will appreciate the value of this enactment. The Swiss law has also a peculiar feature, by which, when rules affecting the management of a factory are about to receive official approbation, the workmen are to be called upon to express their opinion and move amendments. In the second section of Dr. Napias' book we have many useful details as to the contamination of watercourses by the residue from factories, and the various measures that have been adopted in different countries for the mitigation of the evil. Then follow details as to the ventilation of factories, the dangers of mining, and the measures to prevent accidents from the use of machinery. The third section treats in a similar manner all that relates to the poisonous substances employed in various industries, and we have not only the laws of all countries affecting the same, but some account of the inventions destined to modify the dangers, and a summary of the opinions expressed by some of the best authorities. There are also a few illustrations that are of considerable assistance to the reader. Lastly, we have in the latter part of the volume a sort of dictionary of substances used in manufacture, or trade, their classification, the legislation affecting the same, and general suggestions as to what dangers may arise and how they can best be avoided. This dictionary, which takes up nearly two hundred pages, is most useful for facilitating prompt reference. Indeed, Dr. Napias may be congratulated on the thoroughly practical and complete character of his work. It is also written with scientific disregard of that patriotic vanity which is a weak side in the French character. There is no attempt to extol France or to conceal the superiority of the legislation of other countries. Dr. Napias, whom we know personally to be one of the most patriotic of Frenchmen, has understood that the production of a strictly correct and impartial work is the highest of all tributes, and the best means of winning for French scientific literature a prominent position in Europe. Finally, we might mention that, as Government inspector of factories and unwholesome dwellings, Dr. Napias is especially qualified for the task he has undertaken. Dr. Napias is also the Secretary-General

to the French Society of Public Medicine and Professional Hygiene, Corresponding Member of the Belgian, Italian, and Russian Sanitary Societies, Knight of the Legion of Honour, and Officer of the French Academy.

*Lock Hospitals and Lock Wards in General Hospitals.* By FREDERICK W. LOWNDES, M.R.C.S., Surgeon, Liverpool Lock Hospital. London: J. and A. Churchill. 1882.—The purport of this pamphlet is to give information as to the history and work of the existing lock hospitals and wards, and in that way to show how very deficient this special form of hospital accommodation is in London, and nearly all other large towns. Mr. Lowndes has not attempted a complete justification of these institutions, but he points out that all of them relieve the suffering of innocent as well as of vicious people. In Liverpool the Lock Hospital was originally a part of the infirmary, and is now under the management of the committee of that institution, and Mr. Lowndes is so well satisfied with the working of this plan, that he strongly advocates its adoption in other towns. He believes that a separate hospital is far better than special wards in a general hospital for these particular patients, but, owing to the great difficulty everywhere experienced in supporting them as independent institutions, he strongly urges that they should be provided and managed by general hospitals. Unfortunately many general hospitals are already so pressed for funds that they will not feel encouraged to undertake fresh responsibilities.

*A Handbook on Diseases of the Skin, with especial reference to Diagnosis and Treatment.* By ROBERT LIVEING, A.M., M.D. Cantab., F.R.C.P. Lond., Physician to the Department for Diseases of the Skin at the Middlesex Hospital, &c. Third Edition, revised. London: Longmans, Green, and Co. 1882.—In the first edition of this popular and well-written handbook, published in 1878, Dr. Liveing made it the feature of the work to draw attention specially to the differential diagnosis of the various diseases. The usual detailed descriptions of the symptoms—e.g., of eczema, were avoided as far as possible, when not bearing particularly on the diagnosis. The excellence of the book was at once recognised, but it was felt that its value would be still further enhanced if the author extended its scope and included the subject of treatment. This Dr. Liveing carried out in the second edition, indicating the special treatment best adapted for each particular disease, and adding a very useful chapter on the therapeutics of skin diseases generally. This necessitated some further remarks on etiology, and the addition of about one-third to the bulk of the book. The third edition has been carefully revised, and we can cordially recommend it as a thoroughly sound, clearly written handbook, with the distinctive features we have pointed out.

*Archives Italiennes de Biologie.* Vol. I, Parts 1 and 2. Turin: Hermann Loescher.—We desire to bring under the notice of our readers a new journal with the above title, which has just appeared under the direction of Professors C. Emery and A. Mosso, and which is intended to place before the world the results of Italian research. It is thought by the editors that many of the memoirs published in Italian are practically overlooked in consequence of the language in which they are written being familiar to but few of the workers in biology. They have therefore, we think wisely, adopted the French language, which is more widely read and understood. It is intended that the new journal should appear every two months at the rate of thirty francs per annum. The first two parts have already appeared, and contain some excellent papers. Some relate to anatomy, others to physiology, and others again to the application of biological research to the diagnosis and treatment of disease. The numbers before us are well printed, and will, we do not doubt, prove of great service in bringing Italian researches into more general notice.

*The Botanical Atlas.* A Guide to the Practical Study of Plants. By D. M'ALPINE, F.C.S. Parts I. to III. London and Edinburgh: W. and A. K. Johnston.—The object of this handsome work is to assist beginners in botany by showing them pictorially every part of the structure of the leading forms of plants. It cannot fail to be of great use to the student who, with the plant before him, employs the Atlas as a guide to show him what to observe; whilst in such subjects as those illustrated in the second part—viz., the bacteriæ and desmidiæ—he will have to rely mainly upon the illustrations for his instruction. Properly employed the pictorial method is a valuable means of education, and worth many pages of text-book description. The author of this Atlas has already published a "Biological Atlas" and a "Zoological Atlas," each of which has been much appreciated. From the careful manner in which this Botanical Atlas has been planned and the admirable execution of the plates, it will doubtless be held in as high estimation as the former works. Without entering into details we may content ourselves at present with indicating our approval of a work which should do something to enhance the attraction that botany naturally has for lovers of nature and science. Each part contains four large plates, and the work is produced at a very moderate cost.

*L'Année Médicale, 1881.* Paris: E. Plon and Co. 1882.—This is the fourth year of this useful publication, which is produced under the editorship of Dr. Bourneville, assisted by the younger school of writers, some of whose names are already well known in literature. The great difficulty in all such summaries is to limit the extent over which analysis should extend, and, so far as one can judge, the work has been done here with a fair amount of discrimination. It will be observed that many of the papers abstracted in the volume were communicated to the International Congress—evidence of the important position which the proceedings of that Congress took in last year's scientific work. An innovation in the plan of the volume appears this year in an appendix containing brief memoirs of some of those who died during the year, together with a summary of the chief reforms in medical education and hospital management in Paris, in several of which the energetic editor has himself taken a prominent part.

## THE NUREMBERG MEDICAL CONGRESS.

THE above Congress was to have assembled this year at the Berlin Hygienic Exhibition; but the recent destruction of that building, together with the opportune invitation of the local association of Nuremberg, decided the presidential body to select the latter city for the meeting. An additional reason for doing so was the fact that the Bavarian Exhibition contained many objects of medical and sanitary interest, so that the members of the profession who attended the Congress would derive some practical benefit from their visit to South Germany.

In his opening address Dr. Graf of Elberfeld referred to the advantages derived from controversy on disputed points of theory or practice, which associations like the present encouraged. He called attention at some length to the relations of the State to the medical profession, which are at present, it would seem, in a somewhat unsatisfactory position. Legislation has been proposed in reference to various professions and callings, and medicine seems, according to the Government scheme, to receive but scant courtesy, doctors being in some provisions of the statute bracketed with theatrical managers and tavern-keepers. The main object of the recent Congress was to elaborate a scheme which could be put forward as an amendment to the Government proposals, and as representing the general opinion of the profession as to questions of medical organisation, the value of which principle is admitted.

The discussion which took place on the various proposals

laid before the Congress was carried on with warmth; and some of the motions put forward were to a certain extent modified before being accepted by a majority of those present. While paying regard to the rights and privileges of the profession, considerable attention was given to the discussion of the duties to the public which are incumbent upon its members in connexion with social as well as sanitary questions.

It was decided to send delegates to this year's Natural Philosophy Congress at Eisenach; and prospective arrangements were made for the discussion at next year's Medical Congress, as a principal subject, of the best means of applying Imperial legislation to counteract the spread of epidemic disease. On that occasion it is also contemplated to discuss the prolongation of the existing time of probation for intending practitioners.

The resolutions adopted referred to five main topics, with reference to which numerous detailed suggestions were agreed to.

*Admission as a Practitioner.*—It was decided that any measure bearing on this point ought to be submitted by the Government to the medical profession through its representative body; also that the use of non-German titles of Doctor of Medicine should not be allowed without the permission of the respective Governments.

*Duties and Rights of the Profession.*—Under this head the independence of medical men as to the right to regulate their charges was asserted; as also the exclusive right of duly qualified medical men to official appointments, whether under Government or of a municipal character. The Congress approved of the compulsory registration by medical men of the occurrence of infectious diseases within the scope of their practice, and of gratuitous certificates of cause of death being obligatory. The principle was also accepted that the State has a right to claim in sanitary matters the active co-operation of medical men, a suitable allowance being made for the loss of time and personal trouble thus incurred.

*Representation of the Profession.*—The detailed controversy which took place under this head does not seem to have led to a settlement of the vexed question, whether universal suffrage amongst medical men, or the voting of those belonging to recognised associations, should be the principle adopted in the election of the national and provincial medical boards, which would officially represent the profession in questions affecting its relations with the various Governments. The resolution adopted inclines towards a certain amount of local option being allowed in each country or province under this head.

*Tribunals of Honour.*—It was resolved that the right of exclusion from the various associations should be vested in a tribunal elected from amongst the members, with the right of appeal on the part of anyone brought before that body to a higher tribunal, also composed of medical men. The latter authority, likewise, would have jurisdiction as to matters affecting medical men who might not be members of any association. The object of these provisions is probably to render groundless the claims which the State has put forward as to the right of suspending in certain cases medical men from the exercise of their professional functions.

*Medical Certificates for Insurance Companies.*—The extension of the various forms of life and accident insurance which is now being encouraged by the Imperial Government has, it would seem, imposed duties upon the medical profession which, being exercised for the protection of insurance companies from fraudulent claims, should be the object of special remuneration by them. It was resolved that the attention of the medical associations of Germany be called to this matter, to which it is proposed to devote more attention at the Congress of 1883.

The Berlin *National Zeitung*, in referring to the addresses of Dr. Graf, Dr. Merkel (of Nuremberg), and other speakers, alludes in a friendly spirit to the appreciation which exists in Germany of the value and necessity of medical co-operation in the work of sanitary reform, and expresses the hope that the claims of the profession to due liberty in their action and in their internal organisation will be fully recognised in any legislation proposed by the Imperial Government.

ON the 1st inst. a meeting was held in Queen-square, Bristol, to promote a movement for the erection of an international hospital at Washington in memory of the late President Garfield.

# THE LANCET.

LONDON: SATURDAY, AUGUST 12, 1882.

THE degree to which the various phenomena of the cardiac contractions depend upon nervous mechanisms, or upon peculiarities in the function of the muscular tissue itself, is a subject on which opinion has been widely divided among physiologists, and is not yet altogether settled. Spontaneous rhythmical action seems to depend on the nervous ganglia, since only those parts of the frog's heart which possess such structures go on beating if isolated. But the apex of the heart, in which no ganglia can be demonstrated, can be excited to rhythmical contraction by stimuli, as the constant current and the influence of an alkaline solution—a fact which seems to demonstrate that rhythmical action cannot, after all, be entirely due to visible nervous structures. There is, however, one part of the heart, the bulbus arteriosus, in which, when isolated, contractions may occur, although no ganglia have been found in it. A mechanical stimulus excites in it a series of contractions. MUNCK has therefore assumed that ganglia must exist in the bulb although they have not been discovered. LÖWITT has recently searched afresh for any ganglionic structures which might explain these contractions. In the greater part of the aortic bulb he could find none; only at one spot in the superior segment of the bulb he found a mass of nerve-cells which may be called the bulbar ganglion. It is invisible to the naked eye, but is situated at the point at which the two arteries emerge. This structure receives nervous filaments from the external coat of the bulbus arteriosus, and they present ganglionic cells in their course. It is probably by these fibres that the bulbar ganglion is connected with those of the auricle and ventricle. LÖWITT, indeed, believes that fibres from this ganglion pass directly to the muscular fibres of the ventricle, without passing through BIDDER'S ganglion, and that stimulation thus passes from the bulbus arteriosus to the ventricle, and thence to the auricle and the sinus. This is the order in which the effect is manifested, and is invariable, as long as the ventricle is intact. A connexion between the bulbus arteriosus and the auricle can only be by nerves: there is no continuity of muscular tissue from one to the other, since they are entirely separated by connective tissue. The nervous connexion between the two is, however, demonstrated by the passage of a stimulation from one to the other after the whole of the ventricle has been removed.

If BIDDER'S ganglion is removed, the heart, as ECKHARDT has shown, stops, but soon recommences its pulsations. Stimulation of the pneumogastric then causes an arrest of the heart in diastole. There must therefore be another communication between the vagus and the muscular tissue of the heart besides the chief path through the sinus, the interauricular septum, and the ganglion of BIDDER. AUBERT assumed that the pneumogastric fibres were directly connected with the ventricular muscles, but this theory is rendered unnecessary by the discovery of the bulbar ganglion.

Of the various collections of nerve tissue in the heart the most considerable is the auricular ganglion; that of the sinus venosus is next in size, then come BIDDER'S ganglia, and, lastly, the bulbar ganglion. According to LÖWITT the cells of this are unipolar, like those of the spinal ganglia.

An opportunity of observing the effect of stimuli applied to the human heart, such as was afforded by the celebrated case submitted to royal experiment two hundred years ago, is necessarily extremely infrequent. A somewhat similar case has, however, lately occurred in Germany, and has been examined by ZIEMSEN. A woman, forty-five years of age, suffered from an enchondroma, which occupied the greater part of the anterior wall of the thorax. The removal of the tumour left an opening into the left half of the chest, eleven centimetres long and nine wide, at the bottom of which were seen the two ventricles of the heart, and part of the left half of the diaphragm. If the heart was touched with the finger, each normal contraction of the ventricles was followed by a second of shorter duration, involving both ventricles, even when one only was touched with the finger. Compression of both femorals, and of both subclavians, had no other effect than to lessen the frequency of the cardiac contractions. Direct stimulation with the faradaic current did not modify the frequency or the rhythm of the contractions, and caused no sensation. Stimulation with the voltaic current caused, however, a distinct contraction of both ventricles. Moreover, when the positive pole was applied to the heart, and the circuit was closed, there was a considerable acceleration in the frequency of the contractions, from 80 to 100. A strong current caused a peculiar sensation not distinctly localised, but no actual pain.

The power of rhythmic contraction of the isolated apex of the heart is manifested under the influence of an alkaline solution, and is therefore supposed to be excited normally by the stimulus of the alkaline blood. The mode of action of such a stimulus has been experimentally studied by LÖWITT, by tying the ventricle on a manometric cannula, after having removed BIDDER'S ganglion. If an alkaline solution is passed through the heart, it responds to a stimulus by a series of contractions, but without the solution only a single contraction is produced. The composition of the solution, and the pressure under which it is injected, both influence the result. The cessation of the rhythmical contractions appears to be due, not to the loss of the ability to contract rhythmically, but to the cessation of the stimulus, for the contractions recur when the stimulation is renewed. The longer the alkaline solution has remained in contact with the heart, the slighter is the intra-cardiac pressure which suffices to renew the contractions, and the longer is their duration. The mode in which the alkaline solutions act has also been investigated very carefully by MARTIUS, who comes to the conclusion that their influence is merely to enable the heart to utilise the residue of blood and serum which may remain in its substance and inner surface. When all nutritive substances of this kind have disappeared, the alkaline solution of chloride of sodium has no more influence than an acid solution. Solutions of peptone, caseine, egg-albumen, syntonin, myosin, mucin, glycogen, and milk, are also without effect, while blood, serum, lymph from the thoracic duct, and sero-albuminous liquids may re-establish the cardiac irritability.

Underlying the effect of the stimuli which evoke contractions is the remarkable fact that they are rhythmical, and this seems ultimately to depend on a peculiarity of the muscular tissue. According to MAREY there is a periodical variation in the excitability by a stimulus. He has shown that in the course of a revolution of the heart of a frog or tortoise, the organ passes successively through two conditions. During the contraction it is insensitive to stimuli, which a little later, during the period of relaxation, cause a new contraction intercalated in the series of rhythmical beats. The excitability is very slight during contraction, while it is far greater and gradually increases during the period of relaxation. DASTRE has lately shown that this is true, not only, as MAREY affirmed, of the whole heart, but also of the isolated muscular tissue of the apex. Not only does the excitability progressively increase during the diastolic period, but it lessens during the course of the systole. This character seems to explain the mysterious fact that discontinuous movements may result from continuous excitation experimentally produced, although in the case of the organ under normal conditions the most potent stimulus, intracardiac pressure, varies in its degree so as to constitute an intermitting stimulus. It is interesting to note that the period at which the stimulus is most intense during the systole, in which it is no longer needed, is that at which the sensibility to it is least. The effect of the varying intracardiac pressure in producing the rhythm is beautifully shown by an experiment of DASTRE, in which he connected together two separated hearts, one of the tortoise, the other of the frog. The pressure was raised in one by the contraction of the other. The point of the ventricle of the frog's heart contracted with the rhythm of that of the tortoise, while the base, with the auricles, maintained its own rhythm. Pressure is effective only when applied to the interior of the heart. External pressure has no influence. It thus appears to be the mechanical distension which is the active agent, and it may be that the excitability increases during the diastolic period, partly at least in consequence of the progressive increase in the degree of distension.

Another interesting fact observed by MAREY is that if the normal rhythm of the frog's heart is disturbed by provoking, artificially, a new contraction, after each systole thus provoked there is a compensating pause of such a length as to restore the normal rhythm. DASTRE has investigated the question whether this is to be ascribed to the nervous mechanism of the heart or to the muscular tissue. He finds that while true of the whole heart, it is not true of the apex, and he therefore concludes that the compensating rest is due entirely to the intracardiac nervous structures.

THE growth of wealth must lead to the steady growth of consultation as a feature of medical practice, and the growth of medical science and art must render the questions to be determined in consultation increasingly grave and delicate. The specialisation of work in medical practice is to some extent an inevitable necessity, and it gives rise to questions of treatment in which the ordinary parties to a consultation are necessarily very unequal. Were an ophthalmic or a gynaecological authority of fifty years ago to take part in a consultation now as to the expediency of iridectomy or sclerotomy in glaucoma, or of ovariectomy, or of oöphorec-

tomy, or for the removal of the pylorus in cancer, he would be much perplexed. In regard to some of these procedures, he would be too much puzzled with the morality of them to take an unbiased view of their advantage. Respecting questions arising over ordinary and every-day cases of disease, it must be admitted that the general practitioner holds his own pretty well. If he be a thoughtful man and a careful observer of what he sees, he enjoys an enormous advantage. The continuous observation of cases—not only of cases, but of families in which cases arise, of the habits of the adults, of the diatheses of children, of personal idiosyncrasies, and of general social circumstances—gives him a fund of knowledge which cannot but be most valuable for purposes of advice and therapeutics. Such a practitioner will never be ignored by a good consultee. Both parties are the complement of each other. They will be only thankful for each other's special knowledge, and anxious to throw it into a common consultation for the elucidation and cure of the patient's disease. Differences of opinion respecting either treatment or diagnosis are not likely to occur, and if they do arise are capable of easy adjustment. It is in regard to new procedures and lines of treatment that ethical questions of some difficulty are likely to arise. The occasional triumphs of bold surgery are so astounding that sanguine practitioners or physicians are in danger of requiring the surgeon to go too fast or too far in the use of surgical means. The surgeon in such a case has himself to blame. He is no longer the mere mechanic that he was considered to be when the Colleges of Physicians would not admit to their Fellowship one who insisted on retaining the qualification of a College of Surgeons. In these days eminent surgeons vie with eminent physicians in their knowledge of collateral science, and they lay it under contribution to the perfecting of surgical proceedings. The surgeon has no excuse if he has not power to form an independent opinion even in a medical case, or if in such a case he allows himself to be the mere instrument in an operation of which he does not fully approve. He cannot relieve himself of responsibility for opening an abdomen, or removing a kidney, or for puncturing a pericardium with no fluid in it, simply by representing that he acts at the request of another practitioner. We shall yield to none in admiration of the triumphs of careful antiseptic surgery. But the very brilliance of these triumphs makes it more necessary to revert to the ethical principles which should regulate the surgeon in attempting them, and in attempting to reduce the fatality with which they are too often qualified. These ethical principles become more important than ever for the guidance of the surgeon on the one hand, and for his protection on the other. What are these principles? The first is that he himself should be fully satisfied of the justifiableness of the course he is about to take, and of the probability that it will conduce to the good of the patient and to the credit of the healing art. The second is that if there seems much doubt about the matter he should explicitly say so and represent the prospect of a cure as a possibility, and not a probability, to the patient and his friends, and to the general practitioner. Where the procedure is very risky or unusual, or mutilative, it is clearly desirable that not only the consent of the friends, but that of some authority equal to the operator should be required. We do not say that this is

indispensable. Some of the best surgery now practised had to be begun under the frowns and denunciations of the authorities of the day. But it is extremely desirable, and for want of it one great reputation in surgery collapsed terribly and properly. The times are liberal. There is no disposition to adopt finality notions of what surgery or medicine can do or should do. On this account it is only reasonable that where surgery places life in danger which is not already endangered, and contemplates a permanent and serious mutilation, it should act with caution, with conviction, and with a consensus of opinion.

It is with great satisfaction that we already begin to see the fruit of our endeavour to press the truth about sewer-gas on public attention cropping up both at home and abroad. Brighton is, ill-temperedly it is true, and we fear awkwardly and expensively, but nevertheless after a fashion—stirring itself. Let us hope that when the folly of an irascible and misguided moment has been recognised and abandoned, the authorities of London-super-Mare may be reasonable and accept the counsel, instead of resenting the remonstrance, we have addressed to them. We claim to have been their true though candid friend in this matter; and the time must come, sooner or later, when they will themselves perceive this fact and recognise that our sole object has been the purification of a “health-resort” in which, on public grounds alone, we have a lively interest. Meanwhile there are abundant evidences that what we have written on the subject of sewer-gas and sewer ventilation, *à propos* the special needs of Brighton, has produced results far more extensive and salutary than even we had contemplated. Despite the ridiculous attempts made by some of our lay contemporaries to appease public anxiety, by representing the gaseous emanation from sewers as innocuous if not absolutely healthful, it is beginning to be recognised that the great practical disadvantages of the “main-drainage” and “intercepting-sewer” system, whenever and wherever adopted—namely, the accumulation and return of sewer-gas—must be overcome before the requirements of public health can be held to have been absolutely satisfied.

The necessity of the crisis in sewerage reform is to devise and adopt some efficient mode of ventilation, by which the vapours and gaseous products of decomposition given off by the sewage in its passage through the common sewers may be destroyed, or, if that be impossible, carried harmlessly away. Closed pipes must and will retain, and, under certain conditions, return their vaporous and gaseous contents, unless these are removed by a special system of ventilation. Open gratings in the streets of a populous district are not simply nuisances, but traps for the unwary. So far from the assertion that a “whiff” of sewer-gas is not poisonous being true, it is a painfully well-known fact—indeed it is a matter of common observation—that a purely casual inhalation may produce a peculiarly marked effect. In regard to this, as to other poisons, it often happens that the victim of the evil influence is the person who has been for the shortest time and to the least extent exposed to it. It is so even with an odour. The dwellers in foul air become so habituated to it that they do not perceive the stench that nauseates a chance visitor. That this rule of tolerance

applies to poisons is so notorious that we can only marvel that it is not generally admitted. It is, however, a matter of little moment what may be said or written in apology for or defence of the *status quo* as regards sewer ventilation.

It is an incontrovertible fact that sewer-gas is poisonous; and the only question should be, By what method or means are we to get rid of it? We have no special leaning to—and certainly no sort of interest in—any particular “system.” It is obviously necessary to discharge the gas as far as possible *out of* the respired atmosphere, and consequently it cannot be right to ventilate the sewers directly into the streets. This is a simple common-sense conclusion. No question of the dilution of the poison by admixture with the air can possibly come into consideration where the open grating system is adopted, because the pedestrian, or, if the grating be near an open window, the house occupier, inhales the mingled gas and vapour as it rises from the grating. It may not be perpetually given off, but it makes its way out—probably in gusts—as the varying distribution of heat in the system of sewers and the relative temperature of the external atmosphere may determine. The only rational plan of procedure, as it seems to us, is to ventilate the sewers by pipes rising above the level of the adjacent houses, so that it may mingle freely with the higher strata of the atmosphere, and become oxidised. No one who has had any practical experience in ventilation ought to be ignorant of the fact that the atmosphere is stratified by the zones of heat and consequent currents that traverse and intersect it. Even in a room some twenty feet square and thirteen feet high, there may be three or four practically distinct strata of the contained atmosphere, and a vapour or gas introduced at one level will not *quickly* rise or fall to another. The law of the diffusion and admixture of gases is easily suspended by conditions of local temperature and the play of jets of cold air. Just as mists and fogs may roll on the ground, become entangled by trees, be interrupted by the reverse current of air over a river, or hang suspended over tracts of land which are not yet affected by their presence; so sewer-gas may be disseminated through certain strata of the atmosphere, and neither be diluted by, nor affect, other strata, for an appreciable period of time, quite long enough to bring other conditions into operation, and render its ultimate disposal—the unexpected. The only sensible plan of dealing with a noxious gas or vapour is to destroy it locally where it is generated, or, failing that, to disperse it at a higher level. This is the course of procedure we have recommended in dealing with sewer-gas, and to that recommendation we adhere. The objection that such a discharge is difficult, because, when the sewers happen to be of a different temperature from that of the higher strata of the atmosphere—which is generally the case—a down-current may be set up in the ventilating pipes, is not worth discussing, because in practice the difficulty can be easily got over by employing pipes of different heights, the lowest always reaching above the roofs of the houses, the highest opening at a much greater altitude. When several pipes so arranged are connected with the same system of sewers, it will scarcely ever happen that even for a moment the outpour is interrupted. The discharging orifices lie in different strata, and with the protection of cowls the currents of the atmosphere act in a

way that is found to be compensatory. This is, however, a matter of detail. We only allude to it in passing to note the recognition of a difficulty which has been pointed out, and at the same time to indicate that there is a remedy close at hand.

Our immediate object is, we hope, in a fair way of being attained, and we are glad to know that much collateral good has been done by the discussion in which we have been involved. Everywhere and among all classes of the resident population attention has been aroused, and many extensive and costly measures have been taken to remedy evils which were previously overlooked. There are two points we would again, and more strongly than heretofore, press on the notice of the public: First, the system of ventilating by street gratings *must* be finally abandoned. In some parts of the metropolis the condition of matters in this respect is most unsatisfactory. Second, it is useless to trust to the ordinary traps for disconnecting house-drains from the sewers. This last-mentioned matter is within the control of every householder. Properly constructed disconnecting chambers should be fitted to every house. The present season, when families are leaving town, is, so far as London is concerned, a timely one to have this limited and not very costly measure of safety carried into effect. We venture to hope our suggestion will not be unheeded.

AMONG the many improvements of modern times in connexion with military operations, the provision of hospital-ships for the reception and removal of the sick and wounded of troops on active service deserves special notice and commendation. On the outbreak of the war with China in 1859, two large steam-ships, the *Mauritius* and *Melbourne*, were fitted out as hospital-ships, with every requisite for the efficient treatment and accommodation of the sick and wounded. The plan of the special fittings and the general arrangements necessary for the service on which they were to be employed were prepared and carried out under the supervision of the late Deputy Inspector-General HENRY MAPLETON. The results were so satisfactory, and the advantages arising from this provision for the sick and wounded so manifest, that when the Ashanti campaign was undertaken at the end of 1873, H.M.S. *Victor Emanuel*, a wooden screw steamer of upwards of 5000 tons burden, was selected for a hospital-ship, and was fitted up, under the supervision of Dr. MARSTON, at that time assistant in the Sanitary Branch of the Army Medical Department, for the reception of six sick officers and 250 men. Among the improvements made upon the arrangements of the previous ships was the introduction of a laundry with a patent steam washing-machine, drying-room, and store-room for soiled linen, and an ice-machine capable of making 4 cwt. of ice daily. The *Victor Emanuel* was deemed by the medical officers to be a complete success, and was of great value to the numerous sick and to the wounded in the campaign. As we lately stated, two hospital-ships are to be sent to Alexandria. One of these has been fitted up for the purpose in the Albert Dock, under the supervision, so far as the hospital arrangements are concerned, of Surgeon-Major MOORE. The vessel is the *Carthage*, one of the largest of the Peninsular and Oriental Company's screw steamers, and of 5100 tons burden. She will afford accommodation for

twenty-four sick and convalescent officers and for 220 men, besides the medical staff and duty men of the Army Hospital Corps and the ship's crew. Of the men, 80 will be provided for on the main and 140 on the lower deck. The Staff will consist of six medical officers and one quartermaster, three sergeants, one corporal, and twenty-four privates of the Army Hospital Corps. Accommodation has also been provided for four lady nurses. Surgeon-Major FERGUSON has been appointed senior medical officer in charge. The arrangements of the hospital portion of the ship seem to have been very carefully considered, and to promise favourably for the comfort and welfare of the sick and wounded. Abundant means of ventilation have been provided by windsails, punkahs, and Edmonds' system of ventilating tubes, in addition to the inlets afforded by the portholes when weather permits. The baths have all been fitted with pipes to supply fresh water when deemed necessary instead of salt, and have the usual steam-pipes for heating the water. There is an ice-making machine on board capable of producing 2 cwt. daily, and we understand there are also two similar machines to be landed for use on shore. The *Carthage* takes out an abundant supply of hospital comforts. She has not been fitted with a laundry like that of the *Victor Emanuel*, which we think is to be regretted; it is believed, however, that there will be no difficulty experienced in getting the washing done on shore, and, except on the passage out and home, the vessel is never likely to be more than a few days out of harbour. A tank has been fitted up on board in which any clothing requiring disinfection can be placed and thoroughly treated either with boiling water or with disinfectants, of which there is an abundant supply on board in the form of Condy's fluid, carbolic acid, and chloride of lime. Five and a half tons of ice have been taken on board for use, if required, until the ice-making apparatus has been set in operation, and to preserve the meat and other provisions for the outward voyage. We understand that the utmost harmony has prevailed among all the parties engaged in fitting out this vessel, and that the Admiralty have shown a most praiseworthy desire to carry out the wishes of the Medical Department to the utmost extent of their powers. We sincerely trust that the results may prove as satisfactory as those obtained on the two previous occasions.

## Annotations.

"No quid nimis."

### HEALTH OF ENGLISH HOLIDAY RESORTS.

AT this holiday season the Registrar-General's annual table of mortality statistics in the principal watering-places and health resorts has considerable interest, not only for holiday makers, but also for the authorities of watering-places competing for the favour of the public. The Registrar-General's Quarterly Return just issued contains the mortality statistics for the three months ending June last, relating to 46 seaside and inland watering-places. These statistics afford trustworthy indications of the recent health and sanitary condition of these holiday resorts. It has not unfrequently been objected that these statistics do not always relate to the precise boundaries of the different watering-places. This is so far true that the area of the registration district or sub-district taken to represent the watering-places is in most cases larger than the watering-

place itself. The Registrar-General points out that as the population of the health resort is more urban in character than that of the surrounding district, the inclusion of the latter should in most instances favourably affect the mortality statistics. It has been asserted, however, that the opposite result is thus sometimes produced. There can be no question, however, that the holiday visitor of a watering-place is distinctly interested in the sanitary condition of a larger area than the arbitrary limits of the urban sanitary district, especially as regards zymotic fatality. The mortality statistics of the forty-six English watering-places during the last quarter were exceptionally favourable. The mean annual death-rate of the population of these watering-places, estimated at about a million, did not exceed 16·8 per 1000, the zymotic rate being only 1·72. Compared with the rates prevailing in the whole of England and Wales, and also in the rural districts, the mean watering-place rates indicate satisfactory general health, and freedom from zymotic fatality.

#### THE EGYPTIAN EXPEDITION.

THE past week has witnessed the despatch of the Hospital Ship *Carthage*, of eight field hospitals, and the 1st Bearer Company of the Army Hospital Corps, to Egypt. H.R.H. the Duke of Cambridge, accompanied by the Director General of the Army Medical Department, made an inspection of the *Carthage* on Tuesday last, and expressed himself greatly pleased with the arrangements for the sick and wounded. On the main deck, which is lofty, well lighted and ventilated, the sick are berthed in large iron swinging cots, each provided with a small head table and a punkah. The ports are large, and, except in unusually rough weather, will be open. The lower deck, which is also lofty, is intended for convalescents; here the ordinary ship canvas swinging cots are slung, the men's mess tables being fixed to the deck underneath. Excellent cabins for sick officers, a cheerful day-room for them, in addition to the ordinary saloon, numerous baths, lavatories and closets, have been arranged with much forethought. The dispensary has been specially fitted up by Messrs. Savory and Moore. The medical staff consists of Brigade Surgeon H. Fergusson, Surgeon-Major C. Maunsell, Surgeon Western, Captain of Orderlies Joseph, 27 non-commissioned officers and men of the Army Hospital Corps, and four Sisters from the Netley Nursing Establishment. The medical officers and men of five Field Hospitals embarked on board the *Carthage* on Thursday for conveyance to Egypt. Brigade Surgeon Veale and Surgeon-Majors Macdowell, Warren, Tanner and O'Leary in charge of each, with six medical officers and a quartermaster of the Army Hospital Corps attached for duty.

Brigade Surgeon W. Jackson, C.B., having been appointed to the personal staff of Sir Garnet Wolseley, left for Brindisi, on August 4th, to join the Commander-in-Chief of the expedition. Dr. Jackson was attached to Sir Garnet's staff during the Ashantee and Zulu campaigns. Surgeon-Major F. Howard has left for Egypt in medical charge of the troops in the *Viking*. Brigade Surgeon A. M. Tippetts, and Captain of Orderlies Andrews, Army Hospital Corps, have been ordered to Gozo to form the base hospital on the island.

The 2nd Field Hospital left Portsmouth in the *Pelican* on August 5th, Brigade Surgeon Oliver Barnett, C.I.E., in charge, with Surgeon-Major A. Robinson, Surgeon I. W. Beatty, Surgeon Lyons, Lieutenant of Orderlies Howell, and thirty-seven non-commissioned officers and men of the Army Hospital Corps.

The *Marathon* embarked at Portsmouth on August 5th the 1st Bearer Company, under Surgeon-Major S. K. Ray. The Company went out complete as to men and equipment; the officers attached were Surgeon-Majors R. C. Hickson,

J. Shaw, Surgeons Lucas, Addison, Captain of Orderlies L. Gorman, and Lieutenant of Orderlies Marshall; one Warrant officer and 143 non-commissioned officers and men of the Army Hospital Corps. No. 3 Field Hospital also sailed in the *Marathon*, the *personnel* being Surgeon-Majors Beath, Troup, Surgeons Anthonisz, Mitter, and Lieutenant of Orderlies Enright, with thirty-seven non-commissioned officers and men of the Army Hospital Corps.

Captain of Orderlies Osborne, Army Hospital Corps, left Liverpool in the *Capella* on August 5th for Egypt.

We understand that the dress of the medical officers in Egypt will be as follows:—Frock and trousers, blue serge; helmet white, with dun-coloured puggaree, with black line twisted through it, and blue veil; forage cap, Glengarry, with departmental badge.

#### THE UNION OF NERVES.

M. GLUCK, not long ago, suggested the use of Neuber's "ossein" drainage-tubes (composed of decalcified bone) as a means of promoting the union of divided nerves. His attempts were, however, not successful. M. Vanlair has lately repeated the experiment, avoiding as far as possible any conditions which might have interfered with the results in Gluck's cases, and he has been more successful than the Berlin surgeon. At the first attempt he obtained, in four months, the regeneration of a nerve filament no less than five millimetres in length. From other experiments he has arrived at the conclusion that it will be possible to reproduce nerve segments of almost any length. The details of the operative procedures are not described in M. Vanlair's paper, which was communicated to the Académie des Sciences, and is chiefly occupied by some facts which, proceeding in this manner, he has ascertained regarding the process of regeneration of nerves. These facts corroborate the conclusions of Eichhorst, Ranvier, and Helin, that the regeneration is by a process of peripheral budding. He has also ascertained that a partial restoration of muscular activity, correlative to an anatomical regeneration of the nerve fibres, may occur a long time before the return of cutaneous sensibility. The new growth always commences in the marginal zone of the fasciculi, and only reaches very slowly the axial bundle. Hence the conclusion is drawn that the efficient cause of the proliferation is not the direct irritation due to the division, but the inflammation which spreads from the sheath in consequence of the injury. The maturation of the newly formed fibres proceeds from the periphery towards the centre; the inferior half of the intercalated segment resembles the normal type of structure much more closely than the superior half. The relations which Vanlair has traced between the new segment and the peripheral portion of the nerve are as follows. A distinct fasciculus in the inferior part of the segment may pass through the junction, and then emerge as an altogether independent nerve, to ramify in an adjacent muscular mass. Other bundles pass along the dissociated fasciculi of the peripheral portion without penetrating into their interior, so that a section presents two distinct circumscribed portions, one constituted by young, living, almost microscopic fasciculi, directly continuous with those of the intermediate segment; the other composed of larger fasciculi with degenerate fibres, belonging to the old peripheral segment. Another part of the fibres of the intermediate portion separate and are lost in the connective tissue which forms a swelling at the junction of the old and new portions. Lastly, a small number of new fibres enter the fasciculi of the degenerated fibres, and pass either into the empty Schwann's sheaths or into the interstices between them, and can be traced for a certain distance from the point of section. Thus the peripheral end seems to be the channel for only a limited number of the new nerve fibres, and to constitute rather an

obstacle to the regular progress of the new elements. These observations, if accurate, seem to show that it is a mistake to endeavour to bring closely together the extremities of divided nerves. What is necessary is that the regenerating nerve should be enclosed in some limiting structure such as a Neuber's tube.

#### LIVES CAST AWAY ON THE MOUNTAINS.

It is time to speak out plainly and enter an earnest protest against the miserable waste of human life which seems to be involved in mountaineering. No possible good can be done by climbing the Alps for mere pastime. When a scientific object is in view the risk of life may be justifiable, but nothing can excuse the reckless venture which has no better purpose than the gratification of a caprice or the indulgence of a small ambition. It is not a very great or grand thing to be able to scale the slippery sides of high mountains. The pains incurred, the strength expended, and the skill displayed in surmounting the difficulties of a feat of this description, might be bestowed on many a more useful enterprise. We are not animated by any home-sick or craven sentiment in making this assertion. We know how to appreciate deeds of daring, and can sympathise with those who take pride in manly exploits, but we fail to see the point or purpose of "mountaineering." It is not even as nearly related to *possible* usefulness as ballooning, because it is just conceivable that some day the aeronauts may discover a way of turning their art to practical advantage; but *climbing*, in the Alpine sense, is at best a piece of pure pastime, and often involves a sacrifice of life, as in the recent miserable accidents, which we all deeply regret. A young man engaged in the study of medicine is the last victim to this futile form of desperate enterprise. We will not trust ourselves to speak farther of the matter. It is too terrible to write or think about. A valuable life cast away on the mountains; a career which might have been one of usefulness to humanity blighted! The subject is one of humiliating interest, the "accident" a matter of profound regret.

#### OCCLUSION OF THE EXTERNAL AUDITORY MEATUS.

DR. ORR has recently recorded three cases of occlusion of the external auditory meatus which have occurred in the practice of Dr. S. Sexton of New York. In the first case, a man, aged thirty-nine, who had previously suffered from occasional otorrhoea and tinnitus aurium on taking cold, fell from a truck and cut his left temple and ear. This caused great swelling of the whole side of the head, and an abscess formed in front of the pinna, which was opened. Six weeks after the accident, when he came under Dr. Sexton's care, he complained of deafness in the left ear, vertigo, especially on rising quickly, very distressing tinnitus, and a sense of fulness in the ear. The orifice of the auditory meatus was found to be occluded by a dense integumentary membrane, except for a minute aperture at the upper and back corner, which just admitted a small probe. Through this aperture a small blunt-pointed tenotome was passed, and a ring of the skin a quarter of an inch in diameter was removed. Blood and inspissated pus were evacuated, and two days later "a firm wad of cotton-wool, thoroughly saturated in the secretions in which it was found," was removed, and "normal hearing was at once restored." The patient knew nothing of the introduction of any wool into his ear since he was thirteen years old, but the plug was evidently of more recent date than this. The meatus was dilated at first by a speculum and then by plugs of cotton-wool, and all aural symptoms subsided. The second case was similar in that it occurred through injury. A man, aged sixty-two, gave the history that when a boy he was trodden on by a horse, and

his left ear severed from the skull. It was cleansed and replaced, and ultimately firmly adhered. But it was not quite accurately adjusted, being placed too far forwards: the opening of the meatus was quite closed by tegument, the lower portion of the auricle seeming to cover it. A tiny sinus opened in front of the tragus, and through this some thin matter and wax could be occasionally squeezed. By firmly pressing on the skin over the meatus the man experienced a bitter taste in the mouth, and there was slight tenderness over the mastoid process. The third case presented itself in a young girl aged thirteen, who had suffered for many weeks with discharge from the right ear. To prevent the child scratching the auricle, she was kept in bed lying on the inflamed ear. "This caused an adhesion of the raw parts about the margin of the concha." When seen, the external auditory canal was completely closed by a diaphragm of the common tegument, situated about the junction of the cartilaginous and osseous portions of the canal, slightly concave and very smooth. Should any signs of middle ear mischief arise, Dr. Sexton intends to open the canal without delay.

#### PRACTICAL CLASSES IN SCOTLAND.

WHILE much is said and written (in the south) with regard to medical education and examination, it appears that a complete change in the curriculum of the Scotch universities is being quietly, and almost without comment, effected. By means of practical classes the student's work has been much increased, and the requisite expense has been almost doubled, and this without more than a passing word in the University Court, as each teacher asks that his course of practical instruction should be recognised or rendered obligatory on the part of the student. The full force of this change will be more evident if an examination of the subjects now taught practically be attempted. These are not all as yet compulsory, but the student somehow understands that even when not so his chance of success at his examination is materially assisted by the information obtained at the class, while others fear that offence may be given to the professor if they abstain from such attendance. The practical classes now organised in some or all of the Scotch universities are these:—Anatomy, Physiology, Chemistry, Botany, Natural History, Materia Medica, Toxicology, Midwifery, Surgery, and Pathology, in connexion with the regular classes, while the name is legion of those less regular, and conducted by lecturers on special subjects. These last, too, become more necessary every year, as the ordinary subjects get overgrown and unfit to be coped with in the time allotted to them. Nor can we look for any decrease in the practical department of teaching. To meet these extra facilities the examinations for the M.B. degree have recently been divided, so that they may be taken at four, instead of three, periods, as heretofore it was found that all the extra teaching did nothing to reduce the number of those who were unsuccessful in their examinations. In consequence of the amount of work, it is now customary among the best students to take five or six years to complete the curriculum, while many of those who attempt to finish in the usual period of four years get so frequently remitted, as well as disorganised in their succession of classes, that they ultimately find themselves behind their less hopeful brethren. It appears hard that poor students should be overweighted, as they must now be, by extra classes, extra fees, and other expenses; but the supply of candidates continues so great that it does not seem likely to unfavourably affect the public interest were the curriculum extended to six, or at least five, years, while it is certain that this would not be more than enough for the ordinary student to obtain a fair acquaintance with the extensive field he requires to culti-

vata. While increased value is very properly given to practical work, attention might profitably be directed to the question of curtailing the number of lectures compulsory in some of the more easily demonstrated subjects. In some way the amount of classwork must be lessened, or the period of study must be lengthened. There are other matters which may with advantage be considered in this connexion.

#### ORIGIN OF THE OLFACTORY TRACT AND STRUCTURE OF THE OLFACTORY LOBES.

SIGNOR GOLGI, in the last part of the "*Archives Italiennes de Biologie*," states that he has made a series of sections through the olfactory lobes, with a view of determining the connexion of the cells and strands of the olfactory lobes. He finds that there is in man and mammals a superficial layer, continuous with the tractus olfactorius, which gradually becomes thinner posteriorly and stretches towards the gyrus hippocampi; a thicker layer of grey matter, rich in ganglion cells; and a layer of nerve fibres, not very clearly defined from the deeper layer of ganglion cells with which they are connected. He maintains that two kinds of nerve cells exist in the grey substance of the lobi olfactorii—one set the processes of which divide into extremely fine fibrils, and are lost in the delicate plexus of the neuroglia, and a second set the fibres of which, though they divide and subdivide, yet preserve their individuality. The fibres of the tractus olfactorius sometimes curve away from their longitudinal course and enter the superjacent grey matter obliquely. The deeper fasciculi of the lobus olfactorius may be traced to the corona radiata, and some, perhaps, into the anterior commissure. Some of the nerve fibres of the olfactory tract originate in the plexus of fine nerve processes of the lobi olfactorii, but are not directly continuous with the ganglion cells of this region. Other fibres, again, are directly continuous with the processes of the ganglion cells.

#### WHAT HINDERS NOTIFICATION OF INFECTIOUS DISEASE.

We direct attention to a letter in another column, entitled "*Notification of Infectious Disease*." It bears not on the main question of the expediency of requiring notification of cases of infectious disease to be made to the sanitary authority either by the medical man or by the householder, but on some of the consequences of letting into the secrets of practice the representatives of the sanitary authority. We are not familiar with the local Act under which the nuisance inspector acted in this case, but if he were acting within its powers it must be a remarkable piece of legislative work, and confer on the inspector gifts as well as powers enough to make the plodding practitioners of medicine envious. The case is this: The town concerned is one in which the Notification of Infectious Disease Act is in force. Under it our correspondent, a medical man, had certified on June 6th to the medical officer of health that F. W.— was suffering from scarlet fever; thereupon, on June 6th, the nuisance inspector visited the house and forbade the patient's father, a cabdriver, plying for hire, but offered him work in the town's service, which he was unable to perform. On June 18th, twelve days from the certification of scarlet fever, and only about six days from the commencement of the infectious process of desquamation, the nuisance inspector gave leave to the father—who was all the time living and sleeping in the infected house—to resume driving his cab! When the medical man called on the 20th June he found his work very much taken out of his hands. The sanitary inspector had supplied a prescription for a disinfecting oil with which the patient was to be rubbed. The medical practitioner naturally felt indignant at such interference, and wrote accord-

ingly to the Sanitary Committee without receiving any answer from it. The inspector, indeed, called and explained that the prescription was the work of the officer of health, and that it was left under the impression that the doctor had ceased his attendance. We are strongly of opinion that the time has come to acknowledge the right of the sanitary authorities of a community to know the existence and general circumstances of any cases of infectious disease that may occur in the midst of it, and to take steps for the protection of the healthy. This is the inevitable tendency of all recent sanitary legislation, and the merest prudence on the part of a civilised community. Clearly this cannot be done without the aid, direct or indirect, of medical men in attendance on the patient. How this should be secured it is not our present purpose to inquire. But we direct attention to the above case as a typical example of the way in which it is not to be secured, and of the harm that will be done if sanitary inspectors are to be allowed to act with medical despotism, to take away liberty and to restore it, to prescribe, and to ignore the experience of the profession in regard to the duration of the periods of risk in infectious disease. Such a system is not more intolerable to the profession than it will prove delusive to the public.

#### PNEUMATIC DRAINAGE.

A NEW system for the protection of houses from the infiltration of sewer gas, and the disposal of town sewage, has been introduced at Paris and Lyons by M. J. B. Berliez, civil engineer, and former director of the Compagnie des Vidanges, of Lyons. An illustration of this new system can now be seen in working order at the barracks of the Pépinière, Boulevard Malesherbes, where a thousand soldiers are quartered, and with the permission of M. Berliez we were able to examine every detail of the process. Underneath the closets the old cesspool has been emptied, thoroughly cleaned, and converted into a cellar. Here we found M. Berliez's apparatus. From each closet above a pipe communicates with an iron cylinder or drum. Within this first receptacle there is an iron basket which will retain a hard substance, such as a brush, or even an infant if thrown down the drain. The detection of crime is thus facilitated, and the obstruction of pipes rendered impossible. A portable handle, affixed from the outside, is used about once a week to impart a strong rotary motion to this basket; the presence of any hard substance is then detected by the sound, and any accumulation of softer substances macerated and driven out. From this first receptacle, and by natural gravitation, the liquefied sewage flows into a second iron receptacle placed close at hand, within a yard or so. A large ovoid floater occupies the greater part of the space within, the pointed end fitting hermetically an opening at the bottom, where the pneumatic suction keeps the floater in its place. It is not till the receptacle is almost full of water that the floater is able to disengage itself from this suction, and, rising, enables the sewage to escape by passing under the floater into the pipes, where the pneumatic suction carries it away. This suction is produced by a steam-engine situated in the suburb of Levallois-Perret, and the iron pipes, placed within the main sewers, communicate not only with the Pépinière barracks, but with several private houses, and with a dépôt at the Place de la Concorde, where the contents of many cesspools are brought and emptied. The total distance is 4600 metres. It is, therefore, on an extensive scale that the experiment has been tried and so far has worked well, giving rise to no sort of nuisance, and instead of allowing sewer gas to ascend house drains, drawing it, on the contrary, away. It is proposed to place these apparatus under all the houses of Paris instead of cesspools; to draw by pneumatic action all the sewage to dépôts situated in the open country outside

Paris, and there pump it forward distances varying from ten to fifty miles, where it may be used either to irrigate farms or be precipitated and converted into solid manure. It is calculated that the sale of this manure and an annual tax of £2 8s. for every house where the system is applied will cover working expenses and yield a large profit. This tax would be an economy on the present cost of emptying cesspools, and the sanitary advantages secured would be an inestimable benefit. The principal objection to the system, so far as its application to towns such as Paris is concerned, rests in the fact that the iron used for the pipes must corrode under the action of sewage matter, and the slightest leakage would cause a total collapse of the whole system. Careful, constant supervision and prompt repairs would be indispensable. Then, the avoidance of nuisance depends on the frequent usage of the closets, as fermentation would set in if the receptacles were left half full for a few days. Families leaving home would have to carefully flush their closets the last thing before their departure; for though each house would be thoroughly protected from sewer gas, it would not be protected from any noxious gas arising within the receptacles. Fortunately these receptacles are very small, and must, in ordinary households, be frequently and automatically emptied during the course of the day; so that, generally speaking, there would be no time for mischief to arise.

#### THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

THIS Association held its thirty-seventh annual meeting on August 2nd, at Glasgow. The retiring president, Dr. Hack Tuke, vacated the chair in favour of Professor Gairdner, the president for the year. The attendance of members was satisfactory; and several visitors, including Dr. Scott Orr, President of the Faculty of Physicians and Surgeons, were present. Dr. Orange, of Broadmoor Criminal Lunatic Asylum, was nominated as president-elect; and it was agreed that the next meeting should be held in London. Drs. Ingalls of Ghent and Blanch of Paris were made honorary members. Members were cordially invited to neighbouring Scotch asylums, and several days were in this way spent most pleasantly by many of them. Professor Gairdner delivered an able address on the increasing connexion between the so-called specialism of the asylum physician and scientific medicine. The hearty thanks of the meeting would show that a responsive chord had been struck in the minds of members, while Professor Gairdner's election to the chair was deemed another proof of the sincerity and width of their views. Further, thanks were voted to the Faculty for the reception the Association had met with at their hands that day, as well as for liberty to the West of Scotland Branch to meet quarterly under their roof. Afterwards a delightful trip by special steamer to Tarbert was enjoyed, the members dining together on board.

#### A BLOOD DIET FOR THE HERBIVORA.

THE fact that all animals, even the herbivora, are at first nourished on a diet of milk, which must be considered as purely animal, led M. Regnard to suggest that an animal diet might be employed with advantage at a subsequent epoch in their history. The idea is not new, but attempts to verify it by, for instance, feeding horses on meat, raw or cooked, invariably failed in consequence of the disgust which this diet occasioned. It occurred, however, to M. Regnard that an animal substance might be utilised—certainly highly nutritious, of which tons are wasted weekly—viz., blood. The problem was how to present it to the animal in such a form as not to occasion disgust. The blood was heated to 100°C., and the coagulum thus obtained was pressed and rapidly dried in a stove, and then powdered in a coffee mill. It was found to keep well, and to be destitute of odour and of taste, and was given mixed with other food in

doses varying from ten to eighty grammes daily. The experiments were made on lambs which had been abandoned by their mothers. Three lambs were kept on the ordinary diet of beetroot, hay, &c., and to three others the powdered blood was given. The first steadily lost flesh, while the latter increased to three times the original weight, and connoisseurs declared that they had never seen such fine lambs of the same age. The animals surpassed their fellows which had been suckled by their dams both in weight and size, and their coat of wool became doubled in thickness. Experiments of the same kind are now in progress with calves, and promise to be as successful as the others. It will certainly be a matter of high importance if the vast amount of nutriment now almost entirely wasted can be thus utilised. The saving of milk in rearing calves, for instance, would alone be a most valuable item. It appears that this system of alimentation is applicable also to man. In the case of a rickety child of eighteen months the results are said to have been most encouraging.

#### DEATHS UNDER CHLOROFORM AND ETHER.

TWO inquests have recently been held in the central district of Middlesex upon persons dying when under the influence of an anæsthetic. The first case was that of a male patient, aged forty years, who was about to be operated upon by Mr. Coulson in St. Peter's Hospital, Berners-street, for stricture of the urethra. After two drachms of chloroform had been administered by the house-surgeon, the patient suddenly ceased to breathe and died in a few minutes. A post-mortem examination was made by Dr. A. J. Pepper, who stated that the heart was undergoing fatty degeneration, but that all the other organs were healthy. The deceased had not led a very regular life, and was at times addicted to intemperance. The second case was that of a woman, aged fifty-three years, who was admitted into the Middlesex Hospital suffering from cancer of the uterus, which caused obstruction to the bowels. Stercoraceous vomiting occurred three days after her admission. Mr. Henry Morris decided to perform colotomy, and a mixture of chloroform and ether was administered by one of the resident medical officers. After the patient had been inhaling for two or three minutes, she began to vomit, and then suddenly appeared to be choking and ceased to breathe. In both cases the usual efforts for restoration were continued for some time, but without avail. Verdicts of death from misadventure were returned by the jury.

#### PLASTIC SPLINTS IN SURGERY.

DR. SAMUEL N. NELSON, of Boston, U.S., has published in the *Brooklyn Annals of Anatomy and Surgery* a careful paper on the use of Plastic Splints in Surgery. He describes the various kinds of plastic splints in use, with the exception of the varieties of felt, and the mode of application and special features of each. The chief object of the paper is to commend the plaster-of-Paris splint as the best of all—the cheapest, safest, and most reliable. The material recommended for the bandages is “the cheap bleached cotton cloth used for printed calico, before it has received the dressing. It is then free from the vegetable oil with which each fibre was covered, and has not received the filling of earthy and starchy compounds necessary to give the firmness required in finishing, and is equivalent to the surgeon's absorbent cotton.” Dr. Nelson is a decided advocate of the treatment of recent fractures—simple or compound—by the plaster-of-Paris splint, and he gives abstracts from the reports of several American surgeons showing the great success of this plan when applied to cases of fracture of the femur. He considers this treatment not only suitable for all fractures of the bones of limbs, but also for fractures of the spine, ribs, and clavicle.

### EXCISION OF THE KNEE-JOINT.

MR. P. J. HAYES has published in the *Dublin Journal of Medical Science* a table of his cases of Excision of the Knee, and in connexion with this table has described his mode of operating and treatment. He makes the usual incision across the front of the joint, divides the lateral ligaments at once, and is careful not to cut the structures uniting the bones behind. To avoid this he divides the crucial ligaments by cutting downwards on to the tibia, and in removing the ends of the bones he saws from before back and not quite through the bones, breaking through the posterior part, and then peeling the soft tissues off the fragments to be removed. The splint he employs is a metal bracketed back splint, the leg piece being an inch anterior to the thigh piece. In addition he has a short splint over the front of the thigh, and this he fastens on very firmly, so as to press the femur backwards and maintain it in exact apposition with the tibia. The leg piece he affixes by plaster-of-Paris, which is continued over the ankle, and so a metal foot-piece is not required. The knee-joint is fully exposed, and can be dressed antiseptically, or in any way preferred by the surgeon. Mr. Hayes's cases numbered fourteen; of these eleven recovered with good useful limbs; in the other three amputation was performed, in one case because the bones could not be kept in apposition; in one case on account of want of repair and phthisis, and in the third from what appears to have been septic diarrhoea; the last two cases died. With this experience Mr. Hayes is fully justified in speaking favourably of excision.

### SPOONS IN THE INTESTINE.

MR. SAMUEL KOHN in the *Medical Record*, New York, July 22nd, relates a remarkable case in which a patient suffering from melancholia, with intercurrent attacks of mania, was removed from the asylum with symptoms of peritonitis; vomiting; pulse 120; temperature 102.5° F.; a pale, anxious countenance, &c., with general abdominal pain, but special tenderness over the right iliac region. Such attacks recurred and subsided alternately over a period of five weeks, partial obstruction occurring four times. The patient said she was "rotten inside," and could not possibly live. One day the mother of the patient came to the doctor's office and said that, that morning, in the fæces of the patient, which she had regularly examined, she had found a long, hard, spindle-shaped mass of fæces, encased in glairy mucus. Examination revealed the edges of several spoons protruding from the mass. Softening and breaking it up she found it to contain three teaspoons, which the doctor found to have every appearance of having lain lengthways in the intestine for a long time, the concavity of one fitting into the convexity of another. All abdominal symptoms disappeared. The patient declared that she swallowed them all in one day with the intention of thus ending her existence.

### INFLUENCE OF LIGHT ON VISION.

M. CHARPENTIER has been engaged in a series of researches to determine the quantity of light requisite to enable the eye to distinguish between two luminous points. He finds that with equal illumination and for the same distance the visibility of luminous points is directly proportional to their surface or to the square of their diameter. That with equal illumination and when of equal size the visibility of luminous points is inversely proportional to the square of their distance from the eye; and, thirdly, that when the luminous points are of equal dimensions, and at the same distance from the eye, their visibility is directly proportional to their illumination. The eyes were in all the experiments exactly accommodated to the distance of the objects, and were free from astigmatism.

DR. DUTRIEUX, the Belgian explorer, who was residing at Alexandria at the time of the bombardment, and during that trying period, when half the city was in flames, calmly pursued his work in the Egyptian Government Hospital, has been rewarded by the Khedive with the title of Bey, and the appointment of Physician-in-Chief to the Hospital. Dr. Dutrieux, in a letter dated July 20th, says: "I have escaped the massacres perpetrated by the criminals and Bedouins let loose by Arabi Pasha against a defenceless population. My house has been burnt and pillaged. As medical officer of the Government Hospital and of the European Hospital, my professional duties detained me in Alexandria, which I have not quitted for a single minute."

WE regret to learn that an accident of a painful and serious, though happily not of an alarming, nature has befallen Dr. F. J. Mouat, who a few days ago sustained a transverse fracture of the right tibia and fibula an inch above the joint, with a dislocation. The latter was easily reduced by Dr. Mouat himself, and there has been no subsequent displacement. The treatment of the injury has, we understand, so far proceeded most satisfactorily, and there is every reason to hope that recovery from its effects will speedily ensue.

THE village of Great Smeaton, Yorkshire, is in mourning on account of the death of Mr. J. W. O. Mogg, the trusted medical adviser of the place. Mr. Mogg was pursuing his round of visits in his dog-cart on the 27th ult., when his horse stumbled, the deceased was thrown out, and, falling on his head, received injuries which resulted in death the following morning.

DR. M'EWEN of Chester has, we regret to learn, succumbed to the attack of paralysis with which he was seized last week. Dr. M'Ewen was for many years prison surgeon to Chester Castle, at which institution, we believe, he succeeded in effecting many important sanitary improvements. He had recently been appointed President of the local branch of the British Medical Association.

RETIRED Deputy Inspector-General of Hospitals, Charles D. Steel, has had conferred on him the Greenwich Hospital pension of £50 per annum, vacant by the death of Retired Deputy Inspector-General of Hospitals, James Taylor.

AT the jubilee held at the Wurzburg University on the 3rd inst., amongst the celebrities who received honorary degrees were Sir James Paget and Professor Huxley.

THE Professorship of Surgery in Berlin, recently vacated by the resignation of Von Langenbeck, has been filled by the appointment of Professor von Bergmann.

THE Royal Commission on Metropolitan Sewage Discharge met on the 4th inst. There were present—Sir John Cooke (in the chair), Dr. De Chaumont, F.R.S., Prof. A. W. Williamson, F.R.S., Dr. Thomas Stevenson, Mr. J. Abernethy, F.R.S.E., and Dr. W. Pole, F.R.S., secretary. The examination of witnesses for the complainants was proceeded with. The Commission will take no further evidence until Tuesday, October 24th; but, in accordance with the terms of the Commission, the Commissioners proceeded down the Thames on the 8th inst. for the purpose of viewing the outfall of the sewage at Barking Creek.

THE recent bazaar in aid of the funds of the Cottage Hospital at Egham has produced the sum of £90 for the benefit of the institution.

THE  
BRITISH MEDICAL ASSOCIATION.  
FIFTIETH ANNUAL MEETING,  
*Held at Worcester, August, 1882.*

THE proceedings of the Association commenced on Tuesday last, the 8th inst., a large number of members arriving in the town on that day. There was every promise of fine weather, and the visitors to the ancient city had opportunities of viewing its famous works, the Art Exhibition, the Cathedral, &c., in addition to engaging in the more serious business with which the programme was filled. After an informal reception by the Mayor and Corporation, the members marched in a body from the Guildhall to the Cathedral, where service was held, followed by a brief sermon by the Dean of Worcester. At 6 o'clock the Mayor and Corporation entertained the President and officers of the Association at dinner.

At 8 P.M. the first general meeting was held, when Mr. Barrow of Ryde, the outgoing President, yielded the chair to Dr. W. Strange. A cordial vote of thanks was passed to Mr. Barrow on the motion of Mr. Wheelhouse, seconded by Dr. Joseph Rogers, and the President delivered his inaugural address, which, although lengthy, was admirably adapted to the occasion. Space will not permit us to give more than the briefest abstract of this address. It commenced by a reference to the fact that the Association on this its fiftieth anniversary was revisiting its birthplace, and therefore the occasion was a most suitable one, both for retrospect and for looking forward to the future. Instead, then, of dwelling upon the history of the Association, he proposed to deal with the "revival" and "survival" of medicine in these kingdoms, and to trace the evolution of the medical mind during the past half century, and then to make a forecast of what the future is likely to be. He described the period 1830-40 as one pregnant with mighty changes, political, social, and scientific. The political collapse was accompanied by a corresponding mental stagnation, and science gained no hearers. Then came the reaction, and the era of scientific discovery set in, whilst political enfranchisement accompanied the increase in commercial and social intercourse. The idea of combining and forming associations for the diffusion of knowledge led to the initiation of the British Association, followed a year later by the foundation of the Provincial Medical and Surgical Association in the city of Worcester by Charles Hastings and his small but devoted band of coadjutors. Looking back to the condition of medicine at that time he pointed out that "that decade was distinguished by a galaxy of names, the like of which, at one period of time, the world has rarely if ever seen." The characteristics of those men whose names had since become as household words were patient research and observation of facts and thorough conscientiousness in the use of them; and, secondly, unswerving courage and truthfulness in announcing those facts to the world. Authority was being questioned on all sides, and he instanced the sensation created by Lawrence's celebrated lectures on the natural history of man. Dr. Strange praised highly the literary works and style of the men of those days, and advised modern medical authors to carefully peruse the works of those masters before putting pen to paper. "Evidence of the increased activity in medical research was afforded by the publication of the 'Cyclopædia of Practical Medicine,' edited by Forbes, Simon, and Conolly, two of whom later founded the *British and Foreign Medical Review*. The theory as well as the practice of medicine was being overthrown, and the action taken by Hastings in founding the Association was to place the provincial practitioner in almost as good a position as his metropolitan brother. And what was the condition of the provincial practitioner at this time? With the exception of a few local physicians of the older stamp, solemn, scholarly, and formal, and here and there an apothecary of more than ordinary acuteness of observation, there existed one dead level of mediocrity; men without the ambition to compete with their metropolitan brethren because the means of doing so were denied them. No sparks of genius emanated from their brains, because there was no mental friction to produce them. No doubt it was the inferior education of the general practitioner that made

literature distasteful to him, and scientific attainments rare; whilst the desire for improvement, which might casually arise, found no field for action. So he settled down into the mere copier of other men's prescriptions, and the collector of current nostrums for certain symptoms. Bundles of prescriptions were handed down from one practitioner to another along with the practice. Having no other idea but that disease was an entity, he set to work to drive it out of the system by the popular means of bleeding, purging, and sweating. If this were the intellectual status of the provincial practitioner half a century ago, were his morals and social status of a higher grade? I am not one of those *detractores temporis acti* who delight in recalling the caricatures—for they were caricatures, even then—of Fielding and Smollett, and, afterwards, of Dickens. Whilst the squire and the parson of the parish did not disdain to take their recreation in the parlour of the village ale-house, what wonder that the village doctor made that same ale-house his club also? But this, and his over-addiction to field sports, sometimes in company with his betters, but more often with his inferiors, drove away all desire for study, even if the means had been at hand, which, generally, they were not. So the top boots and the red coat did duty for the stethoscope and the test-tube; whilst the lancet was thrust into the arm of the too-willing patient as recklessly and ruthlessly as the spur and the whip had been applied to the sides of the animal which brought doctor and patient together. These were the palmy days of the provincial physician. Many times has he been figured, as, with solemn step and well-poised cane, he descended from his lumbering postchaise at the door of some opulent patient. The arrival of this great man in some country town was quite an event, and the signal for all the blind and halt and lame to turn out literally for a touch of the great man's hand. Those who could pay pulled out their guineas; those who could not might, perhaps, count upon getting a glance and a word from the 'Great Doctor,' as he was called, as he passed through the admiring crowd to his carriage in the courtyard in the inn. His grand and pompous manner denoted that he felt himself a head and shoulders taller than the poor apothecary who stood by, meekly trying to catch at the inconvertible dicta as they fell from the mouth of the medical oracle. Well, both species are now extinct, or extant only as fossils in some remote locality." Turning now to the working of the Association, he remarked that the provincial profession in 1832 was scarcely ready for it, but the time was soon to arrive in which several factors operated. "But another event, almost coeval with the founding of our Association, came to the rescue, and helped to make the decade 1830-40 for ever memorable in the annals of British medical literature. This event was the establishment of THE LANCET as the leading medical journal. THE LANCET, indeed, dates back some eight years before this time, but it was a puny thing in the first years of its life. It might have been compared at that time to a wasp buzzing about the ears of the drones of the medical hive; but when remodeled and enlarged in 1831, it began a fresh era. We may now liken it to a weasel, or to a still more unsavoury animal, the polecat, biting, scratching, driving out of their holes, with venomous scurrility the 'Bats,' as it called the hospital surgeons and councillors of the Royal College, and hanging them up, like vermin on a barn-door, to general obloquy. This was the function of THE LANCET, varied only by the publication of a few lectures and hospital cases, obtained amidst all kinds of difficulty and opposition, for several years after its commencement. But the services which this remarkable journal, after it had conquered its own independence, rendered to free medicine in the earlier days of its existence, amidst all its faults, failings, and even vices, were simply incalculable. Monopolies destroyed; hole-and-corner meetings and doings of the corporations, for the benefit of the few to the detriment and exclusion of the many, exposed; pompous ignorance and overbearing imbecility held up to scorn; the oppressed and obscure, but honest and industrious seeker after truth, brought to the front. After a time, feeling its growing strength, this brave journal attacked the Legislature itself. And it was time. Its apathy towards all that concerned the interests of our profession, displayed in its tolerance of the most abominable abuses and monopolies in high places; its utter neglect of the public health; the farce of the coroners' courts; its winking at the atrocious adulterations of the people's food; its inhuman neglect of the sick poor; and its disregard of all decency in respect of the burial of the dead—these abuses were one by one attacked,

and their authors and abettors lashed with a pitiless and unsparring hand, until redress and reform were grudgingly conceded. The man who, whatever his faults, spent the best part of his life in compelling the Legislature to listen to his exposure and his complaints of these gigantic evils, and to redress them, was at length listened to, and admitted into the Legislature itself. None the less does the memory of Thomas Wakley deserve this testimony from us who now possess an organ of our own quite capable of maintaining those rights and privileges for which, in the early days of our Association, we had no weapon wherewith to do battle. The celebrated *Review* was of a different character; it did not deal with satire, or use 'the withering mockery of THE LANCET,' but to analyse and collect all that was of value in medical literature, and it is to be deplored that in this faster, but possibly shallower, age of the present day, this valued journal died of inanition after forty years' existence."

From this survey of the past with a brief reference to medical politics, Dr. Strange passed to the second part of his address, the "Survival of Medicine." He cited the theme or motto of the Association, the advancement and perfecting of medical science and practice, and the increase of helpful fellowship between all its members. The first and chiefest characteristic of the profession was its liberty to think, speak, write, and teach. It judged of the real progress made in the art of medicine, and its verdict of approval was the best reward the faithful worker could have. But liberty might degenerate into licence, and he deprecated the haste and hurry of the age, in which not only all authority was set at naught, but old teachings were paraded as new. Such licence, applied to practice, led to self-assertion, self-laudation, and self-sufficiency, and the evil spirit of quackery within the profession. A second characteristic was philanthropy, in which the profession, ignoring its own material advantage, aimed only at the prevention and relief of human pain and misery. The public was beginning to feel that the profession was not a trade; but we should be on our guard against unreasonable exactions. Added to these was truth; and here he dwelt in eloquent terms upon this great cause of intellectual morality, deprecating mischievous haste in the publication of unformed theories and ill-observed facts. He alluded to collective investigation as a corrective for this, and concluded with some strong and pungent remarks upon the quackery that exists so widely in the practice of the profession. These and other defects could only be combated by hearty co-operation, and he urged them to see whether their Council could not be empowered to act as a High Court of Equity and Ethics, before which all important questions affecting professional honour and conduct might be brought up for judgment.

The report of the Council was then read by Mr. Fowke, the general secretary. It referred to the work accomplished and influence attained by the Association during its fifty years' existence, to the labours of its committees, and to its financial position. It stated that there were now 9563 members on the roll, enumerated the losses by death during the past year, and stated that the following new regulations with regard to the election of members had been adopted by the Committee of Council.

"1. There shall be a standing notice in the *Journal* every week of the meetings of the Committee of Council throughout the year; and stating that gentlemen wishing to be elected Members of the Association must send in their names *twenty-one days* before the meeting of the Committees of Council at which they wish to be elected.

"2. That a list of applicants be in the hands of the Committee of Council *fourteen days* before such meeting of the Committee of Council, and that the branch secretaries be supplied with *several* copies of the list.

"3. That no member be elected by a branch unless his name has been inserted in the circular summoning the meeting at which he seeks election.

"The question of Homœopathy, recently discussed in some branches of the Association, and unfortunately mooted in the addresses in Medicine and in Surgery at the annual meeting at Ryde, has occupied much time and thought on the part of the Committee of Council. Immediately on the delivery of those addresses the idea arose in many minds that the views enunciated by the readers of the addresses had, in some way, been put forward (through them) by the Committee of Council itself; and it was not until the President of the Council, Dr. Bristowe, and Mr. Hutchinson, had severally, and in the most public manner, shown that this was not so, that the feeling was allayed. Following upon

this a memorial was presented to the Committee of Council from one branch demanding the *expulsion* from the Association of a member on the ground of his public profession of homœopathy. To this extreme measure the Committee of Council could not accede. As far as is possible, they have rigidly closed the door of *entrance*, and have made it impossible for a professing homœopath to enter the Association through election by the Committee of Council; and they have called upon the branches to aid them by demanding that every name proposed for election shall be inserted in the circular summoning the meeting at which election is sought. They conceive that, by these means, such effectual supervision will be exercised by the Branch Councils that no homœopath will be able to gain admission, either through the Committee of Council or through the Branches, and that thus both doors of entrance are effectually closed. Against perversion to homœopathy *after admission* they are at present powerless, except by the expulsion of the offender; and this, under present circumstances, they consider *unadvisable*: first, because they hold that such a course would be beneath the dignity of the members of a great and avowedly liberal profession, and, secondly, because it would confer an amount of notoriety which is very undesirable upon those who were expelled. At the same time, the Committee of Council courts a full expression of opinion on the part of the whole Association as to whether it will tolerate homœopathy in its ranks or not; and if it should determine that the profession of homœopathy shall *ipso facto* disqualify from membership, then they conceive that the course will be clear, since the unwitting election of a homœopath would thereby be rendered null, and perversion after election would imply the voluntary cessation of membership. The admirable speech in reference to vivisection, delivered by Professor Humphry at Ryde last year, having met with your strong approval, was ordered to be reprinted for the use of the members of the Association; it was decided to send four copies to each member of the Association, and 40,000 were therefore printed and, with the exception of about 1000, distributed. A member having been summoned to the Bow-street Police-court by the Society formed for the Suppression of Vivisection, on a charge of cruelty to animals, founded upon statements made by him at the meeting of the International Medical Congress last year, your President of Council and Professor Humphry, taking counsel with your Editor, decided to defend the case on behalf of the Association. The charge was dismissed. The expense of defending the action was £75. Your Council trust that the action taken will meet with your warm approval.

"The following resolution has been received from the Physiological Society:—'That the Physiological Society feels deeply grateful to the British Medical Association for the generous manner in which their Council came forward to support the cause of physiological science on the occasion of the prosecution of one of the members of the Society under the Act 39 & 40 Vict. cap. 77; and that the secretary be directed to convey the warmest thanks from this Society to the Council of the British Medical Association for their very valuable assistance on that occasion.'

Reference was also made in the Report to the terms of the motions of which Dr. Milner Fothergill and Dr. Ward Cousins had given notice, and stated that the Stewart Prize would be awarded to Dr. Vandyke Carter, for his "Researches in Spirillum Fever," and the Middlemas Prize in Ophthalmology to Mr. W. Adams Frost, F.R.C.S.

Some animated debating ensued upon the Report; for Mr. Nelson Hardy, who moved its adoption, appended a rider to his motion, to the effect that it be an instruction to the Committee of Council that any member of the Association who professed homœopathy, or any other designation implying a special method of treatment, shall *ipso facto* be deprived of his membership. The motion was seconded by Dr. Moore, and met with the indignant opposition of Mr. Husband, who declared that he had never before heard of such an advantage being taken by the mover of the motion to adopt the Report. He urged that if a crusade were entered into against the homœopaths in the ranks of the Association it would only serve to increase their notoriety, and hinted that there was no legal power to expel them. Dr. Joseph Rogers took the same line, and the President ruled Mr. Hardy out of order, who accordingly converted his "rider" into an "amendment" to the motion to adopt the Report, moved by Mr. Husband, seconded by Dr. Rogers. Dr. Fitzpatrick seconded the amendment in an energetic speech, urging the Committee of Council to put

their foot down on homœopathy, and demanding the expulsion of homœopaths according to the laws of the Association, fearless of any consequences. Dr. Seaton remarked that no man could be admitted a member who was not a qualified practitioner, and that the onus therefore lay with the licensing bodies—a remark that was strongly dissented from by the majority. Mr. Dix of Hull, having with difficulty obtained a hearing from the excited meeting, put a different complexion on the matter by pointing out that there were at the present time no laws which empowered the Committee of Council to refuse the membership to homœopaths, the laws passed to that effect in 1832 not having been re-enacted when the Association was incorporated a few years ago. The proper course would be to re-enact these by-laws. Dr. Robert Barnes thought the Council had the right to exclude any candidate, as in other societies or clubs; and, in reply to a question Dr. Wade stated that the Council had the power of expelling members on a majority of two-thirds, subject to confirmation by the next annual meeting. The amendment was then put, and was lost by a large majority, only fifteen voting for it. The report was then unanimously adopted.

The next business on the programme was the motion by Dr. Fothergill to alter the By-law 12, referring to the election of editor of the *Journal*. Although notice of this motion had been advertised for many months, yet Dr. Fothergill evidently thought it more prudent that it should not be put to the vote, for it was stated by Mr. Wheelhouse that a letter had been received from him asking that another time should be fixed for it. Dr. Ward Cousins then moved the resolution of which he had given notice to a greatly diminished audience. His speech, which was an amusing definition of the actual working "centre" of the Association, contained some forcible arguments in favour of the changes he advocated—viz., that the President of the Association be an *ex officio* member of the *Journal* and Finance Committee, and that four of the elected members should retire annually, and be eligible for re-election for two years; Dr. Grigg seconded the motion. Mr. Wheelhouse, the Chairman of the *Journal* and Finance Committee, deprecated the continual change in its composition which this would effect, and pointed to the financial prosperity of the Association as evidence of the good work done. Dr. Fitzpatrick strongly urged the adoption of the motion, which would infuse new blood into the Committee. Mr. Husband proposed that the question be referred to the Committee of Council for consideration, and Mr. Barrow seconded the proposal, adding, however, his surprise that the President of the Association was not *ex officio* a member of any committee. The President in putting the question agreed with his predecessor's remarks, and Mr. Husband's resolution was carried by 38 votes against 11. The meeting, which had been very animated, adjourned at a late hour.

At the Council meeting held on Wednesday morning, an invitation to hold the meeting of 1883 at Liverpool was unanimously accepted, with Dr. Waters, of that city, as president elect. An invitation to Belfast for 1884 was also presented.

The Address in Medicine was subsequently delivered by Dr. W. F. Wade of Birmingham. He began by stating that the circumstances of the law suggested retrospection, and proposed to recall some of the actual facts of medicine as it existed when the Association was founded and some others which have occurred since. He referred to the fact that only a few years before the weekly medical press had been established and experiences were being recorded, which are all the more to be prized since they were written in a spirit of truth, bloodletting pervaded all branches of practice, and formed the chief therapeutical resource. Not many years before 1832 a weekly medical journal, which still maintains its high character, was instituted under the then appropriate name of THE LANCET. In a few years after this date, the title of this periodical had well-nigh become an anachronism; for a revolution of opinion had taken place; the time had come for a reconsideration of ancient dogmas, and that reconsideration in many instances led to their effacement. A truer insight into the *vis medicatrix nature* led to the abandonment in many regions of practice of the stern measures for "assisting nature," and the use of "expectant medicine." Amongst other influences which led to this was the historical fact of the Hahnemannian therapeutics, the underlying doctrines of which were incapable of being received by the scientific mind. They demonstrated, how-

ever, the recuperative powers of nature, for, "rightly or wrongly, cures apparently wrought by such mediation were, and are judged to be, instances of spontaneous recovery." But systems are only swept away because of their fallacies or the faults of those who administer them, such as ignorance of the teachings of science or inattention in their application to special cases. A second source of error is a too rigid adherence to the dictates of science. "Disguise or dislike it as you may, it is not the less certain that in the treatment of disease we have no firmer basis than the doctrine of probabilities." But in all departments it is the same; and there is no reasonable cause for discouragement or despair in the fact, though it is a reasonable cause for reflection, care, and thoughtfulness. Especially needful is it to guard against meddlingness in medicine, in desperate cases. In the onslaught against the abuse of bloodletting Marshall Hall led the way, and by prolonged and careful experimentation he advanced powerful arguments against the practice, being, like Harvey, compelled to reiterate his views and the experiments on which they were based before he could carry conviction to men's minds. As a result of this, "Men came to look at bleeding from an exactly opposite point of view to that which they had previously occupied, and began to see that it was not absolutely necessary at the onset of disease; was of doubtful safety as a routine treatment during its height; and at a grand crisis might even be fatal. Can we wonder that in a few short years the practice had ceased to exist?" Another explanation of this change of practice was that so well put forward by Sir T. Watson of "change of type" in disease—a view which compels us to watch constantly the effects of our own operations and of the workings of nature. Every year adds to our knowledge of the structure and functions of the body, of its derangements, and their effects upon organs, and the extent to which these can be controlled by treatment. New instruments, new methods of research, new drugs, and new facts and theories respecting old ones are from time to time presented to us. We may yet have to go much farther in these directions and be less bound by custom than at present. Dr. Wade then adverted to the other side, citing the trial and subsequent abandonment of the treatment of delirium tremens by large doses of tincture of digitalis, and Todd's error of hasty generalisation in advocating the treatment of acute diseases by unlimited quantities of alcohol. Other errors to which medical men are prone are the love of specifics and the confounding of debility and disease. Dr. Wade concluded by exhorting all to aid in the work of making medicine more rational, more truly scientific, and more free from error, than it has been in the past.

At 1.30 the members were entertained at luncheon in the Shire Hall by the Worcester and Hereford Branch, and a bust of Sir Charles Hastings was presented to the City of Worcester. The interest of the meeting was enhanced by the delivery of a speech on the leading incidents of his father's life, by Mr. G. Hastings, M.P.

## THE SECTIONS.

The Sections all met for the first time on Wednesday, at 3, and in each the President delivered a short introductory address. In the Section of Medicine, Dr. T. Clifford Allbutt spoke of the great change that had come over the whole field of medicine during the past fifty years, and traced it to the "power of unity" and the "gift of freedom." "With the earth his servant and his civil rights secured, the final and crowning work remained, to win the freedom of his mind." The first lesson learnt by emancipated mind was "that force and matter are but one subject under two names." Dr. Allbutt then went on to point out that the old therapeutics was passing away, and that in its place a growing desire to prevent the earliest changes and manifestations of disease had sprung up.

## SURGERY.

In the Section of Surgery, Mr. AUGUSTINE PRITCHARD occupied the chair, and spoke of some of the changes he had witnessed during his professional life. When he began work "there were no anæsthetics, no antiseptics, no clinical thermometer, no ophthalmoscope, none of the marvellous and invaluable revelations of the microscope, even the stethoscope itself was young." Body-snatching had just been put an end to by the passing of the Anatomy Act; bleeding, cupping, tooth extraction, and the making of setons

and tissues were all part of the daily work of the surgeon, and *en passant*, Mr. Pritchard advocated a return to a more liberal use of the issue and the seton for counter-irritation. He considered rapidity in operating was almost as essential now as in the days before anaesthetics. Pleading for the more general use of the median operation of lithotomy, he related a case in which he had by this means removed from the bladder a lump of sealing wax which had been passed down the urethra. Just noticing the wonderful progress of surgery in abdominal surgery, osteotomy, and antiseptic surgery, he concluded by referring to Mr. James Luke, Mr. J. F. South, Mr. Spence, M. Pirogoff, Mr. Busch, Mr. Gore, and Dr. Greenhow, all of whom, more or less widely known, had passed away during the year.

After the President's address Mr. J. GREIG SMITH read a paper on Early Operative Treatment of Joint Disease, in which he repeated the opinions he has already published, and expressed the conviction that many cases of excision and amputation should be saved by timely surgical treatment of less severity. Dividing cases of chronic joint disease into three, commencing in synovitis and in inflammation of the red medulla of articular ends of bone, he sketched his treatment as follows:—In cases of synovial disease: (1) simple remedial measures, including counter-irritation of this part; (2) a free incision into the joint, and the removal, by finger, knife, or scissors of all purpy tissue, followed by drainage for about two weeks; this failing (3) excision. In cases of medullo-arthritis: (1) rest as obtained by encasing the limb in plaster-of-Paris; if this fail, (2) cut down on the bone and gouge out all the diseased bone; and this failing, (3) excision. Mr. Smith advocated the practice of aseptic surgery in these operations.

Mr. MORRIS followed with a paper on six cases of Abscess in Bone, illustrating the value of their surgical treatment. Mr. WM. THOMPSON then read a paper on a remarkable case of Rupture of the Knee-joint and Compound Fracture of Patella after suture of that bone, treated by incision, and followed by recovery. Then followed a discussion upon the various topics thus raised. Mr. TEALE expressed his sense of the value of subcutaneous puncture of joints where there is tension and pain; but the chief subject discussed was the treatment of fracture of the patella. Mr. JESSOP and Mr. WHEELHOUSE (Leeds) each related a case of compound fracture of the patella, which was most successfully treated by antiseptic suture of the fragments. Mr. Jessop had employed the same plan in a case of simple fracture, in which he waited three weeks to let the effusion into the joint be absorbed. Mr. WHEELHOUSE and Mr. TEALE each referred to a case of badly united fracture of the patella, by which the limb was seriously impaired, in which they had freely laid open the joint, removed all the uniting material, and wired the fragments; each case was done aseptically and with perfect success.

Mr. REGINALD HARRISON showed the fragments of a phosphatic Urinary Calculus, weighing over 2 oz., which he removed at one sitting by Bigelow's operation. The man, who was under thirty years of age, recovered. Mr. Harrison expressed his preference for the flat-bladed lithotrite, wherever practicable, and also for Bigelow's original evacuator, which he always uses.

Mr. PEARCE GOULD showed the photograph of a Calculus weighing over 3 oz., successfully removed at one sitting by Dr. Bigelow. He also mentioned the case of a stone weighing over 2½ oz., of which he had removed by lithotomy, after failing to crush it by Dr. Bigelow's most powerful instrument.

Dr. WARD COUSINS showed a long-beaked staff, which he had found very useful in lithotomy, especially in children. Several speakers, however, thought it would be a rather dangerous instrument if not used with great care. Mr. Browne referred to forty-two successive cases of lithotomy at the West Bromwich Hospital without a death, in one of which the stone weighed 7¼ oz.

At the general meeting on Thursday morning the address in Surgery was delivered by Dr. Stokes of Dublin. He took for his subject the three great advances in Surgery during the past fifty years—namely, the introduction of anaesthetics, antiseptic surgery, and resections of joints. The address was notable for its vigorous defence of Listerism, and for the eloquent indication of experimental research in medicine with which it terminated. A cordial vote of thanks was passed, on the motion of Mr. Teale, seconded by Sir W. Mac Cormac. After the address the Stewart prize was presented to Dr. Vandyke Carter, for his researches in relapsing

fever. The prize was received on Dr. Carter's behalf by Surgeon-Major Walker.

#### ANATOMY AND PHYSIOLOGY.

Professor G. M. HUMPHRY, F.R.S., opened the Section of Anatomy and Physiology by an address in which he referred to the divergence of these two sciences. In reference to anatomy, he said, upon the good, clear, ready knowledge of it, more than upon that of any other branch of his science, depends the power of the medical man, more particularly of the surgeon, to do definite positive good; to form, that is, distinct diagnoses, and to adopt decided treatment; and the want of interest which anatomy suffers from not being a progressive science is more than compensated for by its practical importance. "Here I would remark that I think its paramount and unassailable *locus standi* has of late been somewhat lost sight of in its teaching. The books on anatomy, whether manuals or more formal treatises, commonly contain little or no allusion to the practical import of the several structures and their disposition, and the methods of description have usually no relation to this point. Moreover, the anatomist does not seem sufficiently alive to the value of that kind of physiological knowledge—the knowledge of mechanical adaptation, or morphological relation, and of developmental phenomena—which is the proper associate of anatomy, which appertains to it in the same way and in the same right as the study of process appertains to the study of minute structure. Too often the bare naked facts are marshaled in solemn fulness one after another, not to be digested, but to be gulped again, much as they went down under the examination squeeze." While highly valuing the study of anatomy, pure and simple, as cultivating the qualities of attention, accuracy, and painstaking to a greater extent than other studies, he said he valued more its capabilities to excite interest, to nurture inquiry, and to strengthen the mental faculties by virtue of the practical and physiological expositions which are its legitimate accompaniments, some of which he referred to. He expressed a hope that examinations, which largely influence the mode of teaching, may shortly be improved by a considerable extension of the time devoted to them. In conclusion, after reference to the rapid and progressive advance of physiology, he paid an eloquent tribute to the memory of the much-lamented Mr. F. M. Balfour.

#### PUBLIC MEDICINE.

Dr. ALFRED CARPENTER presided over the section of Public Medicine, and in his opening address reviewed the work done in Hygiene and Public Health by the Association in its early years.

#### PATHOLOGY.

Dr. HUGHLINGS JACKSON opened the proceedings by an address on the nature of post-mortem examinations, and urged upon the general practitioners the advisability of forming a kind of club, and combining to perform all post-mortem examinations ordered by the coroner in conjunction with each other.

A discussion on the Pathology of Diabetes followed, in which Dr. S. Mackenzie, Dr. Pavy, and Dr. Saundby took part. Specimens illustrating other diseases of the nervous system were afterwards exhibited and discussed.

### HEALTH OF THE ARMY.

#### NO. I.

THE Statistical and Sanitary portion of the Army Medical Department Report for 1880 has just been presented to Parliament. Although a little earlier than last year, it is at least three months later of appearing than usual; we trust the new Director-General will take measures to prevent in future any unnecessary delay. The medical portion and the various papers by medical officers and contributions from Netley will, it is to be presumed, be soon put in circulation, in accordance with the arrangements which we brought to notice last year.

The strength of the white troops serving at home and abroad during the year 1880 averaged 159,622, being about 5000 under the numbers in the preceding year. The admissions into hospital per 1000 of the strength amounted to 1157

the deaths to 13·34, the number sent home as invalids to 31·32, and discharged the service as invalids to 21·92, and the proportion constantly non-effective from sickness was 56·89. Compared with the results for the preceding year these ratios show a slight reduction in the admissions and a very marked one in the deaths, the numbers sent home as invalids, and discharged the service, while there has been a very slight increase in the proportion constantly non-effective from sickness. The great reduction in the mortality has taken place in the force at the Cape, Mauritius, and Cyprus, while that in the number of invalids sent home has been at Cyprus and the other Mediterranean stations, and at the Cape, China, and India; all the other commands showing an increase. There has been an increase in the mean daily sick in Bermuda and the West Indies, and in Mauritius and China; at the other foreign stations there has been either a decrease or scarcely any variation from the preceding year. Although the results are on the whole favourable when compared with those of 1879, they are all above the average of the last ten years, except the numbers sent home and discharged as invalids, the difference being especially marked in the constantly non-effective from sickness, which has been above the average both at home and in all the foreign stations except Cyprus and China.

In the United Kingdom the average strength of the troops during the year was 83,895. The ratio of admissions into hospital was 896, of deaths from all causes 6·83, of invalids discharged the service 22·52, and of constantly sick 46·09 per 1000 of strength. Compared with 1879 there has been an increase in the cases of 74 per 1000, of which sixty-two were due to syphilis and gonorrhœa. The deaths were somewhat lower than in the preceding year, chiefly those from tubercular diseases; there was also a reduction in the proportion invalided, but an increase in the mean daily sick, the latter caused by syphilis and gonorrhœa. There does not appear to have been any unusual amount of sickness or mortality in any of the military divisions. There were 94 cases and 18 deaths of enteric fever during the year; of these 18 cases and 3 deaths occurred at Buttevant, 5 cases and 4 deaths at Tipperary, 12 cases and 2 deaths in Dublin, and 10 cases with 2 deaths in the Household Brigade in the home district. There were 96 admissions and one death by delirium tremens, and 73 admissions with one death by alcoholic poisoning, Cork and the Channel Islands furnishing the highest proportion of cases, and the Chatham district the lowest. The usual tables are given of the prevalence of syphilis and gonorrhœa. From these it appears that the admissions into hospital for primary venereal sores were 74 per 1000 of the strength at the fourteen stations under the Contagious Diseases Act, and 167 at the fourteen not under the Act, the admissions for gonorrhœa being 100 and 128 in the two groups. From the table in the report showing the sickness and mortality in the different arms of the service, it appears that the admissions into hospital were highest, and considerably above the average, in the cavalry, the deaths in the Royal Artillery, if the Brigade Depôts be omitted on account of their death-rate being considerably affected by the number of men sent home from the battalions on foreign service, the proportion discharged as invalids in the Foot Guards, and the average constantly sick in the cavalry. No information is given as to the diseases to which the high ratios of cases and of constantly sick in the cavalry have been due, but the subject is one deserving of careful inquiry.

At Gibraltar the average strength of the troops was 4483 men, from whom the admissions into hospital were in the proportion of 738, the deaths of 4·24, the invaliding of 34·80, and the mean daily sick of 43·91 per 1000. These are all much lower than in 1879; but it must be remembered that in that year the sickness and mortality were greatly increased by the unhealthiness of the regiments which had arrived in the garrison from Cyprus. Compared with the ten years preceding 1879, the admissions, invaliding, and mean sick have all been above, but the deaths 2·30 per 1000 under the average. The excess of the admissions was to a great extent caused by syphilis and gonorrhœa. The highest ratio of admissions occurred in the 41st Regiment, which landed on the 11th August. We cannot congratulate the military authorities on their wisdom in thus sending a corps composed of young soldiers to commence their tour of foreign service on the Rock at the very hottest season of the year; a heavy sick-list might have been anticipated. Only 5 cases of enteric fever occurred during the year; but of these 2 proved fatal, both of them soldiers who had recently arrived.

In a strength of 4885 men at Malta, the admissions were 857, the deaths 10·02, the invaliding 18·01, and the mean sick 46·56 per 1000. These ratios do not differ greatly from those of the preceding year, except the deaths, which show an increase of 1·67 per 1000; but they are all, except the invaliding, above the average of the last ten years. The excess in the mortality was chiefly due to enteric fever, of which there were 53 cases and 17 deaths. They occurred chiefly in the latter half of the year; but no information is given in the report as to the barracks from which they were admitted or the corps by which they were furnished, nor is anything said as to their probable cause. The same injudicious arrangement of sending out regiments from England at the hottest period of the year was carried out here as at Gibraltar, and with the same result, the 26th and 38th, which arrived in the middle of August, having furnished a much higher ratio of admissions than any of the other corps. The admissions and deaths among the men of the Royal Malta Fencible Artillery amounted only to 556 and 5·76 per 1000 respectively. No cases of enteric fever occurred, and there were only two deaths in the corps, one by phthisis and the other by accidental drowning.

The health of the troops serving in Cyprus was on the whole very satisfactory; the admissions amounted to 1002, the deaths to 2·26, the invaliding to 18·07, and the mean sick to 53·27 per 1000. The somewhat high ratio of sickness, as shown by the admissions and mean sick, was partly due to the recurrence of intermittent fever among the men of the Royal Engineers and 35th Regiment, who had previously suffered from that disease, but also to the prevalence of syphilis and gonorrhœa; of syphilis the senior medical officer observes: "The disease is still rife in Limassol, and no adequate measures have hitherto been adopted for either its suppression or control." From the end of May till the beginning of October the troops were encamped on Mount Troodos, except a few left at Depôt Limassol and in charge of the camp at Polymedia. To this judicious measure is probably in a great measure due the satisfactory reduction in the amount of sickness and mortality in the island.

In the Dominion of Canada a force of 1670 men furnished 859 admissions, 6·59 deaths, 35·93 invalids, and 46·68 constantly sick per 1000 of strength; the admissions were lower, but the others slightly higher than in 1879; but, except the deaths, all were considerably above the average of the ten preceding years. The reduction in the admissions was a result of the improved health of the 101st Regiment, which in 1879 had a very high sick rate, from its previous service in Cyprus. Five cases of enteric fever were reported, but of these four occurred among men who had just arrived by the *Crocodile* from Bermuda, where, apparently, the disease had been contracted. The number of cases of alcoholic poisoning indicates a very unsatisfactory state as regards temperance at Halifax, the admissions into hospital having been as high as 24·5 per 1000.

At Bermuda, in a force of 1974 men, there were 696 admissions, 9·62 deaths, 29·89 invalided, and 40·15 constantly sick per 1000 of strength. These ratios are higher than those for 1879, and are also above the average of the last ten years. The increase in the cases was most apparent in diseases of the digestive system and in accidents. The excess of the deaths above the average was not more than might be fairly attributed to ordinary fluctuation in limited numbers. There were 27 cases of enteric fever with 6 deaths; of these, 12 cases and 5 deaths occurred in the 99th Regiment. No information is given as to the barracks occupied by the regiment, or those from which the cases were admitted. There is only the somewhat vague remark of the principal medical officer, that "enteric fever has established a footing in every part of these islands, but especially in the two chief military stations, St. George's and Prospect." He also states that it is by no means common among the residents, and that "a fatal case has not been recorded for nearly two years." If this be not a result of defective registration of the causes of death, it points to the necessity for a thorough and careful investigation into the conditions which give rise to the prevalence of the disease among the military. The high ratio of admissions by diseases of the digestive system is largely due to dyspepsia and diarrhœa; it may be a question to what extent the former of these is a result of intemperance, the admissions under the head of alcoholic poisoning and delirium tremens having been 14·7 per 1000 of the strength. "The cheapness and facility in the supply of liquor continue to be the causes of much intemperance."

The health of the troops in the West Indies during the

year was satisfactory, the admissions having been 918, the deaths 8.63, the invaliding 42.43, and the mean sick 42.88 per 1000; these ratios, except the deaths and invaliding, though higher than in 1879, correspond closely with the average of the last ten years; the deaths were  $2\frac{1}{2}$  per 1000 below, and the invaliding considerably above, the average. Fevers were more prevalent than in 1879, and two deaths by them occurred at Up Park Camp, Jamaica, in one of which "the antecedent illness presented a suspicious resemblance to yellow fever." It is, we think, to be regretted that no statement is given showing the relative sickness and mortality among the troops quartered in Jamaica and Barbadoes respectively. A very marked difference formerly existed, and it would be interesting to see in what respects the two stations now differ. We trust this will not be lost sight of in the next volume, when the results will be greatly affected by the epidemic of yellow fever at Barbadoes. The health of the black troops differed little from the average of the last ten years, except that there was an increase in the invaliding and mean sick. The proportion per 1000 of strength was: admissions 1091; deaths 19.23, invaliding 36.63, and mean sick 64.36. Paroxysmal fevers were the most prevalent, and, as is always the case, tubercular the most fatal diseases. Of 21 deaths in the force 10 were by phthisis.

Among the black troops in West Africa the admissions, deaths, and mean sick closely corresponded with the average, being 1546, 22.47, and 62.33 respectively. There were no men invalided during the year. The most prevalent diseases were paroxysmal fevers, which caused more than two-fifths of the admissions into hospital; and next to them diseases of the digestive system. As with the black troops in the West Indies, phthisis was the most prominent fatal disease; it caused one-half of the deaths.

At the Cape of Good Hope the average strength of the troops was 5552, including a small detachment at St. Helena. The admissions into hospital were in the ratio of 797, the deaths 32.24, the invaliding 47.19, and the mean sick 53.74 per 1000. These were all much lower than in 1879; but in both years the mortality was largely due to losses in action. In 1879 the death-rate, exclusive of killed in action, was 35.10, and in 1880 it was 19.99 per 1000, so that in the latter year there was a marked reduction in the losses by disease, though they were double the average of the ten years preceding the outbreak of the Zulu war. Of the deaths in 1880 rather more than half were from enteric fever, and of the 55 from it 46 occurred in the first quarter of the year. It prevailed throughout the Transvaal and Natal. The principal medical officer states "that medical officers have been pretty well agreed in assigning the cause of it to polluted water-supply at the various camping grounds on the line of march, and consider that it was not due to causes in the various stations at which it occurred. . . . Cases of enteric fever and diseases of the digestive system occurred often largely after a corps arrived at its destination, and were confined almost exclusively to fresh arrivals, ceasing after they had been a little while on the station." Of the deaths from wounds in action 59 occurred out of, and 9 in, hospital.

At Mauritius, although the admissions were still very high, there was a reduction of nearly one-third as compared with 1879, and the mortality fell from 25.85 to 5.67. The proportion of admissions per 1000 of strength was 2204, deaths 5.67, invaliding 79.32, and mean sick 98.53. Nearly half of the admissions were from paroxysmal fevers, none of which, however, terminated fatally. The condition of the troops, however, is one that demands serious consideration, seeing that during the last two years very nearly one-tenth of the force has been constantly on the sick list. The senior medical officer urges strongly "the removal of the greater portion of the garrison from St. Louis to the sanitarium at Curepipe, which is situated 1900 feet above the sea level; he observes that there appears to be no military reason against such a step, and he regards it as the only radical change that is likely to affect the health of the troops. Large huts at the sanitarium have been completed, but at present there is no hospital there." Looking to the deterioration of health, which must result from this perpetual prevalence of fever, it would appear to be a most desirable measure alike of economy and humanity to remove the troops from their present unhealthy stations on the low grounds.

At Ceylon the admissions, deaths, and mean daily sick were considerably higher than in 1879, and much in excess of the average of the last ten years. They were in the pro-

portion of 1238 admissions, 25.0 deaths, 58.0 invalided, and 64.24 mean sick per 1000. There was a marked exemption from the febrile group of diseases. The class which gave rise to the largest proportion of cases, and to two-thirds of all the deaths, was that of diseases of the digestive system, dysentery being the cause of eleven deaths. It was most prevalent in June and July at Colombo; "many of the cases were of the hæmorrhagic form, very severe, and rapidly fatal." The principal medical officer observes that "it was remarkable that when this disease was prevalent among the troops at Colombo the civil population there was almost free from bowel affections." He does not, however, afford any information as to the probable causes of its prevalence and fatal character among the military.

The health of the troops in China and the Straits Settlements appears to have been satisfactory during the year; for though the admissions and deaths were a little higher than in 1879 they, as well as the invaliding and mean sick, were much under the average of the preceding ten years. The admissions were 979, the deaths 8.42, the invaliding 19.65, and the mean sick 45.95. These results cannot but be considered satisfactory by those who remember the unhealthy character of Hong Kong when first occupied by our troops. The admissions and deaths were slightly lower in the Straits Settlements than in Hong Kong. There is but little to call for remark with regard to any of the classes of diseases, except the occurrence of three cases of diphtheria at Hong Kong, of which two proved fatal, and the source of which it was found impossible to trace. The ship *Meane* is used as the station hospital for the troops at Hong Kong. The principal medical officer draws attention to the inconveniences and disadvantages arising from this, and strongly recommends the erection of a good hospital on shore, and also points out the urgent need of one for the wives and children of the soldiers serving in the colony.

## THE FESTIVAL AT WÜRZBURG.

WE have been favoured by Dr. Russell Reynolds with his "impressions" of the festival at Würzburg. They will doubtless be perused with pleasure by our readers.

The festival in commemoration of the three hundredth anniversary of the founding of the Julius-Maximilian University has been for some time past fixed to take place from the 1st to the 4th of August of this year; and its occurrence has been one of the greatest interest, not only to Würzburg itself, but to all the Universities of Bavaria, and of Germany, and of many neighbouring States.

Arriving in Würzburg on the 31st of July, the whole city was found arrayed in festal attire. Every street, every public building, and every private house was decorated in the most tasteful manner. Long festoons of flowers and ferns were placed on either side of the main streets, and flags of brilliant colour and device were hung from the roofs and the windows of the houses both small and great. The whole town was full of joyous welcome; and it was most interesting to see the crowds of visitors arriving from all quarters and by every train receiving the hearty congratulations of their friends, who were resident in the city the university of which they had come to honour. The jovial greetings of old students and new, of middle-aged professors with their former colleagues or alumni, were profuse on every hand, and of such kind as to make it obvious that there was much beyond a fellowship in plain scientific work, a real fellowship of heart and life in doing all that could be done to prove the attachment which all felt to their Alma Julia.

Having been delegated by the University of London to be their representative on this festive occasion, it was my honour to be invited to the private residence of the rector, Professor Wislicenus, in the evening of the day before the ceremonies began, in order to meet the delegates and invited guests, and to take part in the selection of those upon whom should fall the duty of speaking for their universities, or colleges, or schools, on the following day. Professor Wislicenus showed, in his own house, the power, and tact, and kindness which, having met together in his person, have made him the revered and able "Rector Maximus" of the university.

On Tuesday, August 1st, at 9 A.M., religious services were held in the Catholic cathedral, the Protestant church,

the Jewish synagogue. Sermons appropriate to the occasion were preached in the first by Professor Dr. Hettinger, in the second by Dean Wiessinger, and in the last by the Rabbi Bamberger. Musical performances of high character accompanied these services. At eleven o'clock the guests and deputies were received in the garden hall of the royal residence, and ushered to the White Hall of the palace by the band playing the old "fanfare" of the University of Prague. The procession was one of most striking character as it passed by the splendid gallery that leads from the garden entrance to the hall. The costumes of the officials of the town, of the university, of the schools, and of the army, were gorgeous in the extreme. The dresses of many were such as, except on like occasions, are rarely seen; and many of those present looked as if they had stepped out of the picture frames of those represented by the artists of three and four hundred years ago.

The main business of the morning was that of receiving, from quite numberless universities and schools, addresses of congratulation. The Rector called upon selected speakers to address the University of Würzburg in the names of their various colleagues, and then he delivered a powerful address upon the advantages that the university had conferred, and thanked the assembled deputies in a most warm-hearted manner.

It was very curious to one who has seen much of English universities at their festive occasions to observe the stately decorum with which the whole of this proceeding was gone through. There was no applause either by voice or hand or foot; and there was profound, even solemn, attention directed to every word that was uttered. Even when Virchow and many other distinguished speakers left the rostrum there was no applause, but there was a slight vocal cheer when Canon Stubbs, of Oxford, finished his well-phrased speech, and when the representative from Amsterdam concluded his. Still further, it was very interesting to observe the entire absence of anything that elicited either a laugh or even a smile; there was throughout a pleasurable, not grim, sense of seriousness in the whole proceeding, such, as it seems to me, befits a great university act; and this was the more striking when contrasted with the overflowing hilarity at private entertainments, and in all the social gatherings of friends.

In the afternoon it was arranged that there should be a garden party in the palace gardens at five o'clock, and dancing was to commence at ten; but, alas for many, the rain came down in torrents, and that part of the festival was unfortunately not carried out, as it was hoped that it might be. Yet, in spite of "weather," which science, even if it can predict to some extent its changes, has no power at present to control, crowds passed under umbrellas to the grounds, and, I have been credibly informed, some dancing was accomplished.

On Wednesday, the 2nd, the "Great Festival Day," the proceedings commenced at tea in the morning in the University Church, by the performance of Beethoven's overture, Op. 124. Then followed the address, the "Festrede des Rectors," Professor Wislicenus. This most eloquent discourse commenced with an account of the history of the university, and especially of that portion of it which has been presented since the 200th anniversary took place. The Rector showed how it had struggled to be free from all theological thralldom, and in what manner, and to what degree, it had succeeded. On the previous day he had spoken warmly of its thorough catholicity, but to-day he rose to a high degree of fervour, speaking of its earnest struggle as worthy of the spirit of the martyrs. "If," said he, "the very being of science is to seek and find the knowledge of the truth, and this for the good of all, then it lies in its very essence that it can endure no fetters, and the only limits to its advance must be those fixed in the nature of man. No man can point out the way to him who is the pioneer into the region of the unknown; the awakening of his scientific insight is the result of the teaching of the higher schools." Professor Wislicenus has no doubt with regard to the future, but is convinced that it may be confidently left to the "unconquerable pressure onwards of humanity in the search for truth—Das walte Gott." At the conclusion of his address, which was received with loud and long-continued applause, the Deans of the several Faculties recommended the conferring of honorary degrees upon many learned professors of many universities, and the proceedings terminated with music.

At three o'clock on the same day there was a festal dinner,

at which between three and four hundred delegates and guests were present. This was so unlike anything that occurs in England, that some description of it may be interesting to your readers. The dinner began at three and lasted until seven. Everyone appeared in full evening costume, with white cravats and gloves, and bedizened with medals and orders, such as Hood said might have "delighted the eyes of a miner." The menu was exhaustive, and the viands and wine of the best; but what was very curious was the arrangement of the toasts. Before the soup was half finished a signal was given, and everyone rose to hear Prince Theodor Carl (the cousin of the King) propose the health of his Majesty. This was received with appropriate honours, the Prince alluding to his own personal relationship to the medical profession, he having passed through a course of medical instruction, and to the present time occasionally seeing patients in consultation.
